BANCROFT, RICHARD, in *Biography*, archbishop of Canterbury in the reign of James I. sprung from a good family at Farnworth in Lancashire, and was born in September 1544. Having finished his education in the university of Cambridge, he rose by quick gradations to very distinguished stations in the church. The Puritans were the objects of his bitter invectives. Accordingly, in a sermon delivered at St. Paul's cross, on the 9th of February 1589, he accused them, in very intemperate language, of ambition and covetousness; alleging that the principal cause of non-conformity and schism was the prospect of plundering bishoprics, seizing the endowments of cathedrals, and scrambling for the remainder of the church revenues; and accusing the laity among the non-conformists of an intention to dissolve the bonds of property, and to introduce a community of goods. He strongly represented the danger of permitting private men to contest the authority, and violate the constitutions of the church, exposed the absurdity of extemporary prayers, and maintained the divine right of bishops, in terms which, in the judgment of sir Francis Knollys, one of the queen's counsellors, were injurious to the supremacy of the crown. This sermon, preached, as Strype supposes, at the instigation of archbishop Whitgift, furnished ample evidence of Bancroft's inveterate hostility against the Puritans. As one of the commissioners for ecclesiastical causes, he adopted rigorous measures for the suppression of heresy and schism; and he was an avowed enemy to sects and innovations of every kind. Writings against episcopacy, or recommending any other mode of church discipline, were treated

treated by Bancroft as seditious, and he pursued their authors as enemies to the state. His zeal recommended him to ecclesiastical preferment; and in 1597, he was advanced to the see of London, and the management of the ecclesiastical affairs of the kingdom devolved upon him. In the celebrated conference between the bishops and the Presbyterian ministers, held at Hampton court in 1603, Bancroft took an active part; and when the king required satisfaction in the three points of confirmation, ablation, and private baptism, he undertook to explain and vindicate these branches of ecclesiastical discipline, as they were exercised in the church of England. In the prosecution of this conference, and with a view to its speedy termination by an act of authority, he moved the king, that an ancient canon, that "Schismatics are not to be heard against Bishops," should be revived; and that, according to a decree of an ancient council, which prohibited any man to plead against his own subscription, those of the opponents, who had subscribed the communion-book, should be set aside. These absurd and unjust proposals were rejected by the king. When Dr. Reynolds, on the part of the non-conformists, moved for several alterations in doctrine and discipline, the bishop fell upon his knees before the king, praying that care might be taken to provide a praying clergy, as the services of the desk were too much neglected, and the duty of a parish priest wholly restricted to the pulpit; that till men of learning could be procured for every congregation, homilies should be read, and their number increased; and that pulpits might not be turned into batteries, from which every malecontent might be allowed to vent his spleen against his superiors. These requests, whether well or ill-founded, were evidently pointed against the non-conformists. Upon the lord chancellor's taking occasion to argue against pluralities, and expressing a wish that some clergymen might have single coats before others had doublets, adding also, that he had bestowed benefices in the king's gift upon this principle, the bishop of London replied, "I commend your honourable care that way; but a doublet is necessary in cold weather." The good bishop, it is said, spoke feelingly, for he had himself experienced the comfort of warm cloathing. In 1604, bishop Bancroft was elected and consecrated to succeed archbishop Whitgift in the see of Canterbury; and in this high station he retained his intolerant principles, and pursued the same measures against the non-conformists. To this purpose lord Clarendon (Hist. vol. i. p. 88.), in his eulogy, testifies, that "if he had lived, he would quickly have extinguished all that fire in England, which had been kindled at Geneva, and would easily have kept out that infection which could not afterwards be so easily expelled." For the rights of the church, the archbishop manifested a jealousy, which involved him in a contest with the judges; against whom he exhibited to the lords of the council, complaints of their encroachments on the ecclesiastical courts in granting prohibitions; but these complaints were overruled by the unanimous opinion of the judges, which Coke justly calls the highest authority of the law. In the interior discipline of the church, the archbishop was rigorously exact, urging a strict conformity to the rubric and canons, and making no allowance for diversity of opinion. He enforced subscription to the articles in the most unevasive terms; and it appears, that, not long before his death, forty-nine clergymen were deprived of their benefices for not complying with his rigid requisitions. In 1610, he proposed to parliament a plan for increasing the revenues of the church, by improving the tithes, redeeming lay impropriations, and restoring the practice of mortuaries by repealing the statute of mortmain. Parliament wisely resisted this project, which seems to have been the last public act of the archbishop's life;

for he died of the stone, at his palace at Lambeth, in November 1610, aged 67. His library was bequeathed to his successors in the metropolitan see of Canterbury. Besides his sermon against the Puritans, we have only two tracts, written by him before his advancement to the episcopal dignity, in defence of the church against the non-conformists, intitled "Dangerous Positions," and "Survey of the pretended holy Discipline." The prominent features in the character of this prelate were intemperate zeal and intolerant severity; and if he rendered any services to episcopacy, the general cause of Protestantism owed him little obligation; for nothing could be more inconsistent with the fundamental principle of the reformation, than the restraint and prohibition of that freedom of judgment and choice in the province of religion, which had been asserted and maintained by the predominant party on their separation from the church of Rome. Bancroft, however, though his principles were narrow and temper rugged, possessed a degree of understanding and of activity of spirit, which fitted him for public business, and which enabled him to occupy important stations in the church with a considerable degree of reputation. A letter written by this prelate to king James I., in vindication of pluralities, is preserved in the advocate's library at Edinburgh, and may be read in the first volume of sir David Dalrymple's Memorials. Biog. Brit. Gen. Biog.

BAND, in a general sense, some small, narrow ligament, wherewith a thing is tied or fastened.

We say, a *stay-band*, a *brow-band*, a *bat-band*, &c.

BAND, in *Architecture*, denotes any flat, low member, or moulding. This amounts to the same with what is otherwise called *face*, from the Latin *facies*, which Vitruvius uses for the same thing, and sometimes *fillet*, *plinth*, &c.

BANDS of Columns, properly denote a kind of embossments furrounding shafts of rustic columns, at certain distances, by way of decoration.

These are sometimes plain, sometimes picked or vermiculated, and sometimes carved with decorations of low relief, which are different in every different band.

Columns enriched with these bands, are sometimes called *banded columns*.

BAND, in matters of *Artillery*, denotes a hoop of iron used about the carriage of a gun.

Such are the nave bands, which are iron hoops binding the nave at both ends.

BAND, in *Geography*, a town of Persia, in the province of Mekran, 400 miles S.S.W. of Candahar.

BAND, *Bandum*, is used, in *Middle Age Writers*, for a flag or banner.

BAND of Soldiers, in *Military Language*, so many as fight under the same flag or ensign. Thus Romulus called those who fought under the same manipule (a handful of hay being then used for a flag) *manipulus militum*.

Formerly bands especially denoted bodies of foot; and the French formerly called their infantry *bandes Françoises*.

BAND of Pensioners, is still retained, to denote a company of gentlemen, who receive a yearly allowance of 100l. for attending the king on solemn occasions. See **PENSIONERS**.

BANDS, Trained. See **TRAINED Bands**.

BAND, gives the denomination to a military order in Spain, instituted by Alphonus XI. king of Castile, in the year 1332. It takes its name from *banda*, *band*, or red ribband, which comes across over the right shoulder, and under the left arm of the knight. This order is for none but the younger sons of nobles; the eldest sons of grandees are excluded; and, before admittance, it is requisite to have served at least ten years, either in the army or at court. They are bound to take up arms for the Catholic faith against the infidels.

The king himself is grand-master of the order.

BANDS of a Saddle, denote two flat narrow pieces of iron, nailed on each side the bows of the saddle, to retain those bows in the situation which makes the form of a saddle.

BAND, to put a *l-vo* in *the*, is to nail down the two ends of each band to each side of the bow.

Besides the two great bands, the fore-bow has a small one called the wither-band, and the hinder-bow another to strengthen it.

BAND, in *Surgery*, is a long slip of linen, or some other convenient material, intended for the purpose of binding and surrounding any part of the body. When a band has been rolled up for use, into a cylindrical form, it is generally denominated a **BANDAGE** or **ROLLER**.

BANDA, in *Geography*, the chief island of a group, which comprises five others, lying close to one another, and situated in the Eastern Pacific ocean, east of Celebes or Macassar, south of Ceram, and south-east of Amboyna, in about S. lat. $5^{\circ} 45'$. E. long. $130^{\circ} 30'$. These islands are called the Spice or Nutmeg islands, and also Banda isles from the name of the principal of the group. Banda formed the second government of the Dutch to the eastward. The first of these islands is Neira or Nera, where stands the chief settlement of the province; it has a spacious and commodious harbour, but difficult of access; ships anchor under the cannon of two forts, called Belgica and Nassau, the first standing on an eminence, and commanding the whole extent of the island and of the harbour, as well as fort Nassau; the defence of it would require a garrison of 400 men, and yet the whole number of military in all the islands scarcely ever exceeds 300. The next island is that of Banda, Lantor, or Lonthoir; it does not exceed eight British miles in length from west to east, and the greatest breadth at its eastern extremity may be five; it has a fort and two or three redoubts. The third and fourth in importance are Pul-way or Way, and Pulo-run or Rohm: upon the first of which is a small fort, and upon the other a redoubt. The other two are Rozingen or Rossigen, in which there is a redoubt, and to this island the Dutch company often banish their state prisoners; and Gunung-api, Gonong, or Ganap z, which has a volcano constantly emitting smoke, and often flames. The nutmeg-tree is chiefly cultivated in Neira, Gonong, Ay or Way, and Lantor or Banda; and it flourishes not only in the rich black mould, but even amidst the lavas of Gonong, which is the highest isle, the summit being 1940 feet above the sea. When the English admiral Rahnier took possession of the islands of Amboyna and Banda, which he seized without resistance, in February and March 1796, the annual produce was about 163,000 pounds of nutmegs, and 46,000 pounds of mace. The hurricane and earthquake, in 1778, almost annihilated the nutmeg-trees in Banda, so that the Dutch have become the dupes of their own avarice. From 1796 to 1798, the English East India company imported $817,372\frac{1}{2}$ lb of cloves, $93,752\frac{1}{2}$ lb of nutmegs, and $46,730\frac{1}{2}$ lb of mace, besides considerable quantities of each in private trade and privilege goods, amounting to about a third part of the above. The ground being chiefly occupied with these precious plantations, cattle and grain, &c. are imported from Batavia, at the distance of three or four weeks' sail. The inhabitants of the Banda isles were found to be 5763. The English were expelled from Lantor and Rohm, at a period prior to the massacre of Amboyna; but seized the whole Spice islands in 1796, and restored them to their Batavian masters by the treaty with France in 1801.

To the government of Banda belong likewise several other islands in the neighbourhood, known by the appellations of the South-eastern and the South-western isles. Their inhabitants are in alliance with the company, and furnish a

considerable quantity of provisions, consisting of wild-boars, stags, sea-cows, and other articles of food, which they barter at Neira for piece-goods and other necessaries. This trade, however trifling, is very beneficial to the inhabitants of Banda; and it is supposed, that the province would derive greater advantages from it, if the company would allow Neira to become a more commercial place: but this is prevented by the suspicious policy of the government. Stavornius's *Voyages*, by Wilcocke, vol. i. p. 331. vol. ii. p. 418.

BANDA, *Iean lanlu* Ruyfch. *Theat. landtsche cocatocha* and *ikan bandan* Jang. Swangi, Valent amb. *banda* Iean Potou, *banda* Renard Pise. in *Ichthyology*, synonymous names of the species of *CORYPHANA*, called by Gmelin *pentadactyla*.

BANDAGE, in *Surgery*, is a **STRAP**, a **FILLET**, **SWATHE**, or **BAND**, applied to its peculiar use upon any member, &c. of the body. The nature and application of bandages are a study of considerable importance in *Surgery*; for it often happens that the cure of a local disease depends principally or entirely upon the proper management of them. Their substance and form are various, according to the nature of the case, and the intention to be fulfilled in their application. They may be made of linen, flannel, leather, or cloth composed of different materials. Each of these substances, on particular occasions, has its respective advantages or disadvantages.

The common properties and uses of bandages are—

1. To retain parts in their situation.
2. To separate or keep them asunder.
3. To expel morbid fluids, or prevent their accumulation.
4. To confine dressings or external remedies.
5. To compress and obliterate certain vessels.

The bandages most in use are made of linen or cotton. The linen used for this purpose must have been already worn, but still sufficiently strong, cut according to the direction of the threads, and without seam. In order to prevent its unravelling, the edges may be slightly stitched round, but it ought to have no seams whatever.

As it is often impossible to procure long bandages of a single piece, and we are consequently obliged to form them of several different pieces, they should be sewed together with back-stitches, leaving ends several lines in breadth, which must be doubled round and beat perfectly smooth and even. But in order to avoid all the inconveniences that attend the use of bandages made of linen, it will be best to use fillets of linen expressly manufactured for the purpose, which may be of several different breadths and lengths.

Bandages are distinguished into *simple bandages*, which consist of a single piece, and *compound bandages*, which are composed of several different pieces, and whose application requires greater trouble and skill. They are also divided into *general bandages*, or such as may be applied to several different parts of the body, and *particular bandages*, which are adapted only for one particular part.

Every simple bandage consists of a beginning, middle, and end. The beginning and termination are named its *ends*; and when the bandage is rolled up, they are called *heads*. The middle part of the bandage is called its *body*. When we roll up one end of the bandage to the other, we have a *single-headed* bandage; but when we roll up each end separately only towards the middle, it is then termed a *double-headed* bandage. In order to apply any bandage properly, it is necessary that it should first be rolled up tight and perfectly even. The operator, when he applies it, holds its head between the thumb and fore-finger of one hand, in such a manner that it lies directed upwards in the hand, and the end that has been rolled off is held down with the other hand upon the part till it is sufficiently secured by several turns. In rolling out the bandage, the head must run as close

close as possible to the diseased part, and constantly be turned towards the surgeon; the bandage should never be rolled out too far, and the head should be held neither too tight nor too loose. When we wish to remove the bandage again, we should not pull it forcibly off from any part to which it may adhere, but previously loosen it with warm water. It is then cautiously drawn off from the diseased part, and in winding it off, that part of the bandage which has been rolled off is alternately shifted out of the right hand into the left, and *vice versa*.

To the simple bandages belong the circular bandage, the spiral bandage, the retaining, the expellent, the creeping, and the uniting bandages. To the compound bandages are referred the eighteen-headed bandage, the many-headed bandage, the T bandage, and in some measure also the Tournaïque. Some bandages receive their appellations from the names of the parts to which they are applied: as, bandages for the head, eyes, ears, nose, neck, breast, back, belly, &c.

The *eighteen-headed bandage* may be formed of several (suppose three) pieces of linen, about a foot in length, and ten or twelve inches in breadth, more or less according to the length and thickness of the limb, and all three are laid at the middle over each other. At the middle they are sewed together longitudinally, after which each of them is cut through on each side, till about two fingers breadth from the middle, into three equal parts, which form nine heads on each side. But as in this mode one head covers the other, there always remains a slit between the heads, by which means the limb is unequally pressed upon and secured. This defect may be remedied by arranging the cuts in such a manner that the heads of the middle piece of linen are always covered by a slit and the half of two heads of the two other pieces of linen. This will be the case if, as Loeffler advises us, we give the first piece of linen four, the second three, and the third again four heads. See the *Many-headed Bandage*.

In cases of compound fractures, in which the bandages are frequently soiled, it will be more convenient, as Desault advises, to use a bandage consisting of eleven separate fillets of linen, each a foot and a half in length, and four fingers broad. Four of these are to be laid at the bottom, three in the middle, and again four at the top, at the side of each other: and thus we obtain a twenty-two headed bandage of a more convenient construction. This bandage may still be improved by cutting the middle fillets shorter than the lowest, and the upper shorter than the middle; by which means the bandage will apply far better to the part. Should now any of the fillets be soiled, we have the advantage of being able easily to substitute another in its place; for we need only to sew the new fillet to the old one, and draw it by means of the latter through between the rest, without deranging any of the other parts of the bandage.

The *Circular Bandage*. This bandage may be of various lengths and breadths; it is rolled upon one head, and is used for securing small dressings, such as lint and compresses. It is applied in such a manner that one turn entirely covers the other, so that only the last turn is visible.

Retentive Bandage. This is a common simple bandage, which is used for retaining dressings in their proper situation; and it is applied sometimes with circular, sometimes with spiral, and sometimes with creeping turns.

The *Neck Bandage*. A fillet, two feet or two feet and a half in length, is laid across over the head in such a manner that the ends reach down on both sides to the shoulders; and over this another fillet, five or six feet in length and two or three fingers broad, is rolled round the neck with circular turns. The two ends of the first fillet are then doubled back to the head, and secured to the circular turns with

pins; by which means the circular turns are prevented from slipping off, an accident that is particularly to be avoided when the neck is sore.

The *Double Bandage*, to secure the head, is formed of a first fillet, which is laid across over the head in such a manner that the ends reach down on both sides to the shoulders; and over this another fillet, five or six feet in length and two or three fingers broad, is rolled upon two heads. The middle part of the latter is laid upon the forehead over the first fillet; this is then carried over the ears, round the head to the back of the neck; its heads are then fastened to opposite sides, brought forward under both axillæ, then carried backwards over the shoulders, crossed again, carried under the arms over the head, the heads fastened again, and the rest of the bandage rolled round with circular turns. The surgeon then takes hold of the two hanging ends of the first fillet, carries them down back over the head, and then joins them together, or to the other turns, after having drawn the bandage tight.

The *Expellent, or Expellent Bandage*. This is a common simple bandage, the length and breadth of which are to be regulated according to the purpose for which it is to be used. It is used in cases of ulcers, and wounds made with pointed instruments, in order first to force the pus and blood towards the orifice, and afterwards to draw them from the body, and also by bringing them into contact with the air, to promote their healing up. Before the bandage is applied, all the fluids must be expelled out of the wound, ulcer, or fistula, by rubbing, pulling, or drawing injections into it. When this has been done, compresses of various dimensions are applied along the course of the fore, and particularly at the region of its bottom; and generally it is necessary to have compresses that are graduated at one end, the thickest part of which is applied over the bottom of the fore, and the thinnest over its orifice. An assistant holds the compresses fast in their proper situation, whilst the surgeon applies a single or a two-headed bandage, according to the situation of the ulcer. He commences the application over the bottom of the compress, so as to secure and press it down by two or three turns of the bandage, which he then carries towards the orifice with spiral turns; after which he carries it back again, and finishes with spiral turns. This mode of bandaging may also be used with great advantage in cases in which a flap of flesh has been partly cut or torn off from the body, whilst it still remains attached by one part, in order to make it heal up again in its proper situation; and in this case the bandage becomes an *uniting* one. But when we apply it in this manner, we ought always to be careful to make a sufficient and equal pressure at every point; for otherwise our intention, if not entirely frustrated, will at least be impeded, and the cure protracted.

Godin's Bandage. The four-headed or sling bandage for the head. This bandage is formed of a piece of linen three or four feet in length, and from four to eight fingers broad, both ends of which are slit open so far as to leave the middle part about eight fingers long. It is generally applied with the middle part straight upon the head, so that the anterior ends hang down over the cheeks, and the two others over the ears; and in order that it may lie more firmly upon the head, the edge of the middle part that lies over the forehead, as well as that on the back of the head, is doubled round, so as to form a kind of seam. The two anterior ends of the bandage are then carried over the ears, and fastened at the back of the neck; after which the two posterior ends are carried in the same manner over the ears, and fastened under the chin. The bandage may be applied in a similar manner upon various parts of the head, only it is to

be observed, that the central portion must always be placed over the diseased part, and the ends carried in opposite directions, either crossed or stretched out.

The Uniting Neck Bandage. This bandage is formed in the following manner. The surgeon takes a napkin four double, lays it under the patient's axillæ, and pins it together in the front of the breast. He then takes two pieces of linen, fastens one end of them to the patient's night-cap, and the other to the napkin, in such a manner, that if the wound be situated in the trachea, or at the fore-part of the neck, the ends, after the patient's head has been inclined forwards a little, can be fastened to the fore-part of the cloth, in order to keep the head in that position. But should the wound be situated in the back of the neck, the head may be inclined a little backwards, and retained by the same bandage in that position, by drawing the ends of the two small fillets more backwards, and fastening them there to the napkin.

The application of the T bandage, according to Mr. Evers's method, is however more advantageous, especially for uniting wounds across the throat. For this purpose, we are to take a fillet, three fingers broad and ten feet long, and sew to the middle of it another of equal breadth and six feet long, so as to represent the figure of the letter T. The smaller fillet is now to be slit open all but one foot. In applying it, the part at which the two fillets are sewed together, is placed upon the back of the neck in such a manner that the smaller fillet lies over the back of the head upon the vertex. The two heads are next brought forwards over the shoulders, then carried under the axillæ, which are guarded with compresses, to the back; the bandage is then crossed, brought forwards again upon the breast, and fastened. The slit ends of the smaller fillet are next crossed over the vertex; after which they are carried over the face under the axillæ; the patient's chin, if necessary, being drawn downwards towards the breast, and this fillet is finally fastened like the former. Mr. Kochler has proposed for this purpose a leathern cap with straps, by means of which the patient's head may be drawn into any position that may be necessary. See the T Bandage.

The Inguinal Bandage. The bandage for luxations of the os femoris. This is a bandage eight or nine yards in length, and three or four fingers broad, rolled up into one head.

The Six-headed Bandage of Galen. This bandage consists of a piece of linen from three to four feet in length, and 8—12 fingers broad; its breadth and length being determined according to the size of the patient's head. The cloth is folded in such a manner that its breadth can be divided into three equal parts, and these parts are slit open from both sides, so far as to leave entire in the middle a space of the breadth of a man's hand, by which means six heads are formed. It is applied nearly in the same manner as the four-headed bandage for the head.

The many-headed Bandage. This bandage is formed of a piece of linen or flannel, the dimensions being regulated according to those of the diseased part, into which a number of slits are made at both sides, so as to leave only one part entire in the middle for the purpose of connecting the rest. In applying it, the whole piece is laid under the diseased part; the lowest of the ends, which lies on the outer side, is then brought obliquely upwards on the inner side, and that which lies within is brought obliquely upwards on the outer side, and so on; so that the lower ends are always half covered and secured by the upper. A many headed bandage may also be formed in another way, by cutting a piece of linen or flannel into several strips, of which the one is always longer than the other, but each of the same breadth with the rest. The shortest is generally made a foot, and the longest two

feet in length. All these strips are now laid over each other in such a manner that always half the breadth of the one is covered by the other. To secure the whole, a narrow slip of linen or tape is sewed to them behind and also in the middle. In applying it, the narrowest part of the bandage must always come to lie over the smallest part of the limb. A bandage of this kind will perform the functions of the best applied circular or spiral bandage, and it applies to the parts far better than the eighteen-headed bandage; on which account it may be used instead of the latter.

The T Bandage, the bandage for the fistula in ano. This is a common compound bandage, which is chiefly used in lesions of the neck, the breast, the abdomen, the back, but particularly the genital organs, the anus, the groin, and the perinaeum. It is either single or double. The simple T bandage is formed in the following manner: take a fillet from four to eight feet in length, and fold it together in such a manner as to get the exact middle point. At this middle point sew to it another fillet in a perpendicular direction, and of such length as may be most convenient for the purpose for which it is intended. To form the double T bandage, either two fillets are sewed in the middle obliquely beside each other, or a whole piece is sewed on and afterwards slit open. According to the dimensions of the place to which it is to be applied, it is made more or less broad.

The Creeping Bandage. This is a common simple bandage rolled upon one head, which is applied in a spiral manner round the limb, so that the one turn does not cover the other, but only lies close to it, in such a manner that no part of the limb remains visible. It may sometimes be used for securing compresses and other dressings.

The Scapulary and Napkin. This bandage consists of a napkin, and a scapulary as it is termed. The napkin is folded together, and rolled upon two unequal heads; the middle part is then applied under the arm in such a manner that the largest head is carried over the back, and the smaller over the breast; but both heads are laid over each other, and then fastened. But in order to prevent the napkin from slipping out of its situation, the scapulary is required. This is formed of a piece of linen 2—4 feet long, and half a foot broad. In the middle of the piece a slit is cut, large enough for the head to pass conveniently through it; and in this manner one end hangs down before over the breast, and the other over the back. These two ends are then fastened to the napkin before applied. We may also slit open the ends, and thus attach them more extended to the napkin, by which means they will support it better. This bandage may be used in almost all lesions of the breast, as also in simple wounds of the abdomen.

The Spiral Bandage. This is a common simple bandage, the length and breadth of which must be adapted to the dimensions of the part: the second turn of the bandage always covers the first, and the third and following turns always cover each the preceding turn, either half or a little more, so as to represent a spiral figure. The turns may be made either from the upper towards the lower part of the limb, or from the lower towards the upper; in the first case it is termed the descending, and in the second, the ascending spiral bandage. It is generally applied in the last-mentioned manner, and may be used for swathing whole limbs, by which means alone very oblique diseases may sometimes be cured.

Mr. Theden (Neue Bemerkungen u. Erfahrungen, &c. Th. I. Berl. 1781, p. 1.) was the first who called the attention of the public to the more frequent and rational use of swathing with this bandage; and experience has proved that this practice may certainly be attended with very great advantages. In applying it, every thing depends upon the whole limb being entirely encircled with it from the

the very points of the fingers or toes, so as to leave no part whatever bare, as a tumor would be produced in such a part. The method of applying it to the superior extremities is as follows:—For each finger we are to take a fillet a foot in length, and of the breadth of a finger, and wind it round each finger as well as the thumb in the following manner. The first turn is made circularly round the point of the finger, the second, in order to afford a good hold for the rest, immediately over the first; the third turn covers half or a little more of the second, and the fourth and following turns the same. The ends of these fillets are laid upon the back of the hand, and secured with a fillet from 20 to 40 feet long, and 2 or 2½ fingers broad. With this long fillet, the first turn is made immediately over the fingers round the hand, and for the sake of security, the second straight over the first; but the following turns always cover each one half of the preceding turn, and they ascend as high as the elbow, being applied neither too loose nor too tight; for we must always have it in our power to introduce a finger between the turns in case of necessity. If we intend to wet this bandage with any liquid, we must apply it somewhat looser, as it contracts and becomes tighter when it is moist; but afterwards it must be kept constantly moist, as otherwise, when it dries, it becomes too loose, and is consequently rendered useless. Should the person who applies the bandage, not know how to hit the proper measure of tightness in this case, he may wet the bandage before he applies it.

These turns are carried up as high as the elbow, where, if it be a case of injury from blood-letting, a piece of rag spread with a proper ointment is laid upon the inflamed or ulcerated part, and the bandage is carried two or three times up to the humerus, and back again, so as to form turns like ∞ ∞, as in the operation of blood-letting. If we cannot cover every part by means of these turns, we may lay an oblong piece of linen, 3—4 fingers broad, and a foot long, under the elbow, draw it tight, and secure it above and below with the bandage. The end of the piece of linen that projects under the bandage is doubled back, and another turn made round it, in order to prevent its giving way. The turns are then continued as high as the deltoid muscle, or to the shoulder, and the end of the bandage is fastened to the neck. When the tumor grows smaller, so as to render the bandage too loose, it may be renewed.

In swathing the lower extremities, it is not necessary to bandage each toe separately, and this would also be very difficult on account of the shortness of these members. We may therefore apply the middle part of a piece of linen, about twice the breadth of a man's hand in breadth and length, close to the points of the toes, and turn one part over the back of the foot, and the other under the sole; the two folds of the linen are then to be drawn tight towards the foot, and doubled downwards, both at the great and little toe, towards the sole, where they are to be held fast with the left hand. The surgeon then takes into his other hand the bandage, which may be from 30 to 40 feet long, and 2—3 fingers broad, and secures the piece of linen that includes the toes, with two circular turns, after which he proceeds to carry the bandage with spiral turns towards the leg. In order to obviate the difficulty that attends the bandaging of the heel, we may apply under the sole another piece of linen, somewhat more than the breadth of a man's hand, so as to reach above the heel, surround it with the bandage and draw it tight, then double down the ends, and secure them with the bandage in order to prevent their giving way. For the greater security of the bandage, and in order to prevent the pain which it might occasion by its pressure upon the TENDO ACHILLIS,

we may fill up the depressions on both sides of the tendon, as high as the termination of the calf, with lint, which we are bandaging the limb. As often as it is necessary, namely when any turn is not drawn so as to cover half of the preceding, we must turn the bandage, and this must be done particularly under the calf. When the limb has been swathed, a stocking that fits well should be drawn over it.

Stilted Bandage with Two Heads. This bandage is used after blood-letting at the temporal artery. It is from 16 to 20 feet long, two fingers broad, and rolled upon two heads. Instead of this bandage Mr. B. Bell recommends the use of a well-hardened steel spring, three quarters of an inch broad, and twelve or fourteen inches long, which is covered with soft leather, and of equal strength with the spring of a rupture bandage.

The single Star Bandage. This is a one-headed bandage, from sixteen to twenty-four feet long, and four fingers broad, which is used in some affections of the scapulae.

The double Star Bandage. This bandage is 3—4 fingers broad, 24—32 feet long, and rolled upon two heads: it is likewise used in lesions of the scapulae.

The Bandage for an Umbilical Hernia. These bandages may either be elastic or non-elastic. With infants an elastic bandage is both troublesome and superfluous. Mr. Richter therefore recommends to apply half a nutmeg, wrapped in a piece of linen to the umbilicus, and to secure this with a single adhesive plaster and a circular roller. But lest the bandage should slip, and the plaster together with the nutmeg fall off, he directs the front part of the bandage to be made almost as broad as the hand, and that which lies upon the hips two thirds narrower, in order that it should slip a little upwards or downwards, it may still in some degree help to retain the piece of nutmeg in its place. In order to prevent the bandage from wrinkling, it is made of double linen, and at the front part which covers the navel, a piece of leather is inserted between the two pieces of linen; by which means this part of the bandage constantly preserves its proper breadth. When we wish to change the bandage, we should introduce a finger under the bandage, and press down the nutmeg upon the navel till the new bandage has been applied, lest the navel should again be protruded. Instead of the nutmeg, we may employ for the same purpose a set of graduated compresses, or any other proper hard substance. See the article RUTRUM.

An unelastic bandage for the umbilical hernia in adults is made in the following manner. We take a piece of parchment four or five feet long and four fingers broad, and cut into the middle of it a slit a foot long, which passes over the patient's head when it is applied. To the one end, at both corners, two straps are sewed, which run on in a straight line with the whole. Two other straps are sewed immediately over the former to the margin of the bandage, so that when the whole is laid upon a horizontal surface, they form a right angle with the slip of parchment, on each side. Finally, to the inner side of the bandage a cushion is attached, which is stuffed with horse-hair, cork, or cotton, and in order that it may lie properly, it ought to have a degree of swell round the margin. In applying it, the patient introduces his head through the slit above-mentioned, so that the longer portion of the slip of parchment hangs down perpendicularly over his breast, and the shorter down his back. After the hernia has been reduced, the two upper straps attached to the margin of the bandage are carried round the body and tied upon the back; or if they be long enough, over the cushion in front. The other two are brought through between the thighs, and fastened at the back to the first, or to the upper piece of parchment or linen. But

But as the hernia is not always of equal size, being smaller in the morning, and larger after meals, and as it alternately rises and sinks in inspiration and expiration, it is evident that these elastic bandages cannot adapt themselves to those diversities, as they either render necessary a stronger, inconvenient, and often hurtful pressure, or do not press sufficiently, so that the hernia is constantly in danger of slipping through.

With adults therefore we can expect no security, except in the use of elastic bandages for the umbilical hernia; and of these there are simple, compound, and double bandages. The simple bandage consists of a somewhat broad, round, or oval cushion, and an elastic femicircle. With patients whose umbilical region is more debilitated, an oval cushion is requisite, having in the middle a bulb of the size of a walnut, which comes to lie upon the navel. Mr. Richter also recommends the use of a common bandage for the inguinal hernia, provided in its front with a shield, to the inner side of which a cushion is attached. However, this and the above-mentioned rupture bandages are not sufficiently secure against slipping out of their situation, on account of their being provided only with a single lateral spring.

Mr. Theden has proposed the use of elastic gum for bandages for the umbilical hernia; and Mr. Juville thinks that it may be sufficient with patients that are not corpulent, and when the hernia is small. But as elastic gum loses its elasticity when it grows warm, it has been proposed to supersede its use by the application of spiral steel springs to both sides of the cushion. However, both these methods are liable to the objection, that they produce the same pressure upon the whole surrounding part of the abdomen, as they do upon the navel itself; and consequently the cushion either does not compress the navel sufficiently, or it presses it more than is necessary.

A better bandage than these, for the umbilical hernia, is that of Squire, which consists of a plate, with a cushion sewed to it, and two lateral springs proceeding from the plate, which, when it is applied, firmly embrace the body. An elastic bandage of another kind is that of Suretsche, which Mr. Richter (*Abhandlung von den Bruechen*. Gottingen, 1785, p. 641. tab. vii.) has described, delineated, and in a high degree improved. Two bandages of Mr. Juville for umbilical hernia, of which the one is described and delineated by Mr. Bell, and the other by Mr. Hofer. (*Lehrfacke des Chirurg. Verbandes*. Th. II. Erlangen, 1791, p. 278. tab. xi. fig. 77.) Dr. Alex. Monro, senior, has also described a bandage, consisting of a steel spring, which, after the hernia has been reduced, is placed upon the navel, and retained in this situation by a bandage. It is drawn as tight as may be necessary by means of straps and buckles.

When, as sometimes occurs, the hernia has formed adhesions, either spontaneously, or in consequence of improper bandaging, in which case its reduction is altogether impracticable, we must use a concave cushion, instead of a convex one, that may receive the hernia into its hollow, and prevent the farther protrusion of the intestines. If the bandage be skillfully constructed, the adhesions may gradually be diminished, and the hernia at length reduced.

The writing Bandage. This is a common double-headed bandage, and one of the most useful and indispensable which is used in case of fresh wounds, in order to promote their speedy re-union. Properly it is only adapted for such wounds as run in the direction of the body and limb, and that are situated in parts which admit of the application of a bandage; however, it may also be used in cases of transverse wounds; but then it rather belongs to the compound bandages. It may be formed in different ways: *viz.*

1. According to one method of forming it, its length

must be regulated by the circumference of the wounded part, and its breadth must be equal to the length of the wound. In general, however, it is rather used narrow than broad, and it need always be so long that the wounded limb can be thrice encircled with it. In the middle part it must have a large slit, through which the head of the bandage rolled up may easily be passed. In applying it, the surgeon takes one of its heads into each of his hands, applies that portion of the middle part that is not slit to the side of the limb opposite to the wound, brings both the heads round the limb towards the wound, passes one of the heads through the slit, over the wound, drawing both heads in such a manner as to bring the lips of the wound together; after which the one head is rolled round the limb above the wound, and the other below it. When the wound is deep, a languette is applied under the bandage to each of the lips of the wound, at some distance from its edges; the thickness of these languettes must be proportionate to the depth of the wound, and by means of them the bottom of the wound is pressed together when the bandage is drawn tight.

When the wound is very long, we must either apply several bandages, one at the side of the other, or make several slits in a single bandage, and pass the head through the second slit over the first turn, and there draw the lips of the wound together, and so also the second and the third time. In this case it will be best to make the slits whilst we are applying the bandages, namely, at the place where the two heads meet each other, as otherwise they do not fit accurately to the wound. The application of this bandage, however, requires great accuracy. If it be applied too tight, it excites pain, swelling, inflammation, and frustrates the purpose of re-union; but if it be applied too loose, the lips of the wound do not come into contact with each other, and the re-union is not properly effected.

2. Another more convenient bandage which is equally applicable to longitudinal and to transverse wounds, is that which has already been recommended by Mr. Henkel. (*Anweisung zum verbeß. Verbands*, Berlin, 1767, 8. p. 237. *Tab. XV. fig. 104.*—Also Richter's *Anfangsgruende des Wundarzneykunst*. B. I. *Tab. I. fig. 2.*) It consists of four stripes of linen, each of which is from one to two feet in length, and two or three inches in breadth. The dimensions, however, must always be regulated according to those of the diseased part. These four pieces are united by means of six narrow straps in such a manner, that all the six straps cross each other like the fingers of the hand when folded. In this manner we obtain a four-headed crucial bandage, in which the six narrow straps form the centre of the whole.

When it is applied, the narrow straps, or the middle of the bandage, must be placed directly over the wound, and two of the heads must lie on each side of it, in such a manner that the one entirely covers the other. First, the two lowest heads on each side are fastened quite loose round the limb with circular turns. The two heads above are then also first drawn tight with both hands, and then fastened in the same manner as the former. When this bandage is used, we have constantly a view of the wound, as the narrow straps lie immediately over it.

3. Mr. Boettcher (*Aufwahl des chirurgischen Verbandes*, Berlin, 1795. p. 62. § 71.) has also recommended a very simple bandage for promoting the re-union of longitudinal wounds. He takes a common two-headed bandage, two or three fingers in breadth; and first applies to each side of the wound, at the distance of from half an inch to three inches from the edge, a languette, which in the mean time is held by an assistant; he then takes one of the heads into each hand, and makes the beginning with the middle of the bandage, on the side of the limb opposite to the wound.

The

The two heads are now brought over the longuettes, and in the same manner also over the wound; but this must be done in a very loose manner. The heads are then shifted into different hands, and drawn tight, by which means the longuettes are brought together, and the wound united. The two heads are then swung round each other, over the middle of the wound, then shifted again into different hands, and carried back in the same manner as they were brought forwards to the wound. This turn may be repeated three, four, or more times, according to the size of the wound. The ends are then either entirely worn off in circular turns, or should they not be long enough for that purpose, pinned to the other turns.

Should no unfavourable symptoms supervene, the mending bandage may be suffered to remain in its situation, five, six, and, if the wound be deep, still more days. Great accuracy, however, must always be used in applying it, as the wound is to be united from its bottom; and the dimensions of the longuettes, or compresses, must also be regulated accordingly; for with deep wounds they must be thicker, and with superficial wounds thinner. When the wound is entirely superficial, none are required. When the bandage is removed, the part must be retained precisely in the same position that has been given to it, and the new bandage applied in the same manner as the former. Even after the wound has completely healed, it will still be proper, by way of precaution, to leave the bandage in its situation for some days longer.

The Bandage of the Patella fractured longitudinally. For this purpose is required a bandage from sixteen to twenty-four feet long, three fingers broad, and rolled upon two heads. When it is applied, the hollow of the knee must be bolstered with compresses, and a small longuette, about half an inch thick, laid on each side of the knee-pan. The middle part of the bandage is then laid upon the hollow of the knee, and both heads brought forwards; a slit is then cut into the one part, through which the head of the other is passed, in such a manner that the slit fits to the middle of the knee-pan, after which the bandage is drawn tight transversely. The heads are then carried backwards, but obliquely, so that one comes to be situated higher than the other; and the bandaging is completed with circular turns. In order to keep the leg constantly extended, a well-bolstered ferula or splint is laid into the hollow of the knee, which may be fastened there by the last turns of the bandage. For greater security, the leg may also be inclosed in a box properly lined, which reaches as high as the thigh.

We do not here profess to give an entire treatise on *Bandages*, but only an account of those which are most commonly used. Several authors, both ancient and modern, have disapproved on this subject very amply. In particular, we recommend the perusal of Vidus Viduus, for the opinions and practice of the oldest surgeons, which he has translated from the original Greek, and elucidated by various figures: edit. Lutetiae Parisiorum, fol. 1544. Among the moderns, the best writers on bandages are M. Sue, Thiblaye, Heister, Lombard, and Bernstein; but all of them are too prolix and tedious, especially the French authors.

Mr. John Bell of Edinburgh has endeavoured to simplify this study in his first volume of "Principles of Surgery;" there is, however, a very singular declaration in that part of Mr. Bell's book, *viz.* "Those innumerable forms in which the ancients turned the roller round the head, neck, and body," says he, "are to be found in the treatises of Soranus, Glaucus, Dicoles, and Galen. In their treatises I find nothing but what has fallen into deserved neglect, nothing that I could mention either for your amusement or instruction." See page 129. Now it happens in this instance, if

not in some others, that Mr. Bell has never perused the authors whom he quotes; for he treats of the band a loded to, by Soranus, Glaucus, and Dicoles, have ever descended to their posterity. Galen, indeed, wrote on bandages, and his observations are translated by Valentinus, but in the edition we have already referred to, but certainly Mr. Bell has had no access to copies of any similar works by the three former physicians.

BANDAL, or **Passer**, in *Commerce*, the name of a measure used in the town of London, which is longer a more than half a yard, by which measure a row linen is sold in the markets; whence it is called *bandal*.

BANDALLER, *Bandallier*, or *Bandallier*, a large leathern belt, thrown over the right shoulder, and hanging down under the left arm; worn by the musqueteers in the time of James and Charles I. both for the carrying of their fire-arms, and for the carriage of their powder-charges; which being put up in little wooden boxes, or leathern cylindrical boxes, were hung, to the number of twelve, to each bandaller. Each of these boxes contained a single charge of powder.

The word is originally French, *bandouiller*, formed apparently from *bandouler*, a kind of banditti particularly infesting the Pyreneans, who were formerly distinguished by this piece of furniture; and were themselves so denominated, *quasi band de volieres, a kn't of robbers*.

The French soldiery still retain the bandaller; their horse, their musqueteers, and common guards, wearing it indifferently; excepting for some difference in its garniture. Grose (Treatise on Ancient Armour, p. 293.) says, this contrivance seems to have been borrowed from the Dutch or Walloons.

BANDARMALANKA, in *Geography*, a town of Hindostan, in the Circars, situated at the mouth of the river Godavery. N. lat. 16° 25'. E. long. 82° 26'.

BANDE, or *in Band*, in *Heraldry*, expresses the position of a lion, when he is placed diagonally in the shield.

BANDED, a term applied to a garb, or waistcoat, &c. when the band is of a colour different from that of the garb itself.

BANDEL CAUS, in *Geography*, a town of Africa, on the coast of the kingdom of Adal.

BANDEL, a town in the kingdom of Bengal, situated on the western arm of the Ganges, or Hoogly river. N. lat. 22° 53'. E. long. 88° 32'.

BANDELET, or **BANDELET**, in *Architecture*, any little band or flat moulding, encompassing a column, like a ring; as that which crowns the Doric architrave. It is also called *torus*, which Vitruvius uses for the same thing; sometimes *filix*, *dialma*, &c. It is sometimes used for the three parts which compose the architrave, called by Vitruvius, *capitula*; and which are sometimes also denominated *laminae* or *flat-bands*.

BANDELLO, **MATTHEW**, in *Biography*, bishop of Agen, was born towards the close of the fifteenth century, at Castelnuovo of Scavia, in the Milanese. He entered into the society of the Dominicans; and after many changes of situation, he settled in France; and in 1550 was nominated by Henry II. to the bishopric of Agen; but he paid little attention to the duties of his office. The time of his death is not exactly known; but he was living in 1561. He was principally distinguished as a writer of novels. His collection was first printed at Lucca in 1554, in three volumes 4to. under the title of "Novelle del Bandello," to which was added another volume, printed at Lyons in 1573. The edition of London in 1740 comprises four volumes 4to. In his narrations the author is said to imitate the manner of Boecacio, and to write in a lively, pleasing style; but he has also copied his model in those licentious freedoms, which

were no less suitable to his office, than offensive to the church. He was also author of a Latin version of Boccaccio's story of "Pito et Gilippo," of eleven cantos, in ottava rima, in honour of Lucretia Gonzaga; and of some other works. *Nouv. Dict. Histor.*

BANDELVELLO, or **OLD PORT**, in *Geography*, the name of a good harbour at the mouth of the river Doara, on the east coast of Africa, in the Indian ocean; about twenty-seven leagues north of Magadoria or Magadoxo, on the same coast.

BANDER ABASSI. See **GOMERON**.

BANDERAS, a large bay of the Pacific ocean, on the west coast of Mexico, in North America; running inland between two points of land, the north point called Tintoque, and the south cape Corientes, with an open entrance, and sufficiently spacious for the accommodation and anchorage of a fleet of ships.

BANDER CONGO, a port town of Asia, on the east side of the Persian gulf, and thirty-three leagues west from Bander Abassi. N. lat. 27° 5'. E. long. 55° 8'.

BANDERE, a town of Hindostan, in the circar of Galud, one hundred miles south of Agra, and forty-four S. S. E. of Gohnd.

BANDERET, the name appropriated to the commanders of the militia of the canton of Bern.

BANDEROLE, in *Heraldry*, is a streamer affixed by small lines or strings immediately under the crook on the top of the staff of a crossier, and folding over the staff.

BANDEROLES, in *Military Language*, the ornaments which were given to pikes near the point, in order to render their appearance handsome. These sometimes had the name of pencils. (See *Grofe on Ancient Armour*, ii. 277.)

BANDEROLI, in *Naval Language*, a little flag, in form of a guidon, extended more in length than breadth, used to be hung out on the masts of vessels, &c.

BANDEROLLS, in *Military Language*, an ancient name for camp-colours.

BANDI, in *Geography*, a river of Africa, in the country of Calabar, in Lower Guinea, which runs into the sea by two channels. There is a town of the same name on an island at the mouth of the river.

BANDINELLI, **BACCIO**, in *Biography*, a painter of history, was born at Florence in 1497, and became a disciple of Giovanni Francesco Rustico, a good sculptor. He had the ambition to become a rival of Michael Angelo, in painting as well as in sculpture; but hearing that this great master treated his works contemptuously, he laid aside the pencil, and would never afterwards resume it. As a statuary, he possessed skill and merit, and in that art he deemed himself equal to Buonaroti; however, when he found that the world did not concur with him in opinion, he was much mortified. He died at Florence in 1559, at the age of 62 years. Several of his pupils became eminent artists. The principal of his works are the bas-reliefs of the tombs of Leo X. and Clement VII. at Rome, a St. Peter, a Bacchus, the Laocoon, and some figures of some princes of the Medici family at Florence. His drawing is generally correct, and evinces an extensive knowledge of anatomy; but his muscles are too strongly marked, and he is deficient in grace. *Argenville, Vie de Sculpteurs*. *Pilkington*.

BANDITTI, from the Italian *bandito*, persons profcribed, or, as we call it, outlawed; sometimes denominated *kanitti*, or *foris banniti*.

BANDITTI, or **BANDITI**, is also a denomination given to highwaymen and robbers, who infest the roads in troops, especially in Italy, France, and Sicily. Mr. Brydone, in his *Tour through Sicily*, informs us, that in the eastern part called Val Demoni, from the devils that are supposed to in-

habit mount *Ætna*, it has ever been found altogether impracticable to extirpate the banditti; there being numberless caverns and subterraneous passages round that mountain, where no troops could possibly pursue them; besides, they are known to be perfectly determined and resolute, never failing to take a dreadful revenge on all who have offended them. Hence the prince of Villa Franca has embraced it, not only as the safest, but likewise as the wisest and most political scheme, to become their declared patron and protector; and such of them as think proper to leave their mountains and forests, though perhaps only for a time, are sure to meet with good encouragement and a certain protection in his service, where they enjoy the most unbounded confidence, which, in no instance, they have ever yet been found to make an improper or a dishonest use of. They are clothed in the prince's livry, yellow and green, with silver lace; and wear likewise a badge of their honourable order, which intitles them to universal fear and respect from the people.

In some circumstances, these banditti are the most respectable people of the island, and have by much the highest and most romantic notions of what they call their point of honour. However criminal they may be with regard to society in general; yet, with respect to one another, and to every person to whom they have once professed it, they have ever maintained the most unshaken fidelity. The magistrates have often been obliged to protect them, and pay them court, as they are known to be perfectly determined and desperate, and so extremely vindictive, that they will certainly put any person to death that has ever given them just cause of provocation. On the other hand, it never was known that any person who had put himself under their protection, and shewed that he had confidence in them, had cause to repent of it, or was injured by them in the most minute trifle; but, on the contrary, they will protect him from impositions of every kind, and scorn to go halves with the landlord, like most other conductors and travelling servants, and will defend him with their lives, if there be occasion. Those of their number who have thus enlisted themselves in the service of society, are known and respected by the other banditti all over the island; and the persons of those they accompany are ever held sacred. For these reasons, most travellers choose to hire a couple of them from town to town; and may thus travel over the whole island in safety.

The term is also applied to a sort of free-booters, who pillage in the islands of the Archipelago.

BANDOBENA, in *Ancient Geography*, a town of India, on this side of the Ganges, seated, according to Strabo, on the river Choaspes.

BAND-DOG, in *Zoology*, a variety of the mastiff or *CANIS MOLLOSSUS* of Linnaeus. It is lighter, smaller, more active and vigilant than the mastiff, but not so powerful; its nose is smaller, and possesses, in some degree, the scent of the hound; its hair is rougher, and generally of a yellowish grey, streaked with shades of a black or brown colour. It frequently seizes cattle by the flank, attacks with eagerness, and its bite is keen and dangerous. It is not often to be seen at present. *Bewick's Hist. Quadrupeds*, p. 338.

BANDOL, in *Geography*, a harbour of the Mediterranean, nearly west, and about five leagues from Toulon. It has a fort, and there is anchorage near the east part of a small island, which lies on the west point of the bay that is here formed by the coast.

BANDOLEERS, from the French *bandouliers*, in the *Military Art*. See **BANDALEER**.

BANDON, in *Geography*, the name of a fine river in the county

county of Cork, province of Munster, Ireland, which rises in the mountains of Carbery, and after watering the large and thriving town of Bandon-bridge, and the village of Inishonan, falls into the harbour of Kinsale. It is navigable for large sloops as far as Collier's quay, near Inishonan, from which place Bandon is supplied with English coal. At the confluence of the Bandon and Brinny rivers, a little above Inishonan, the East India company of England formed a settlement about the year 1612, for carrying on iron works, and building large ships; for which purpose they purchased the adjoining woods and lands. They garrisoned a castle, and built three villages; but the opposition given to this undertaking by the natives, soon obliged them to relinquish it. The great woods in the neighbourhood were from that time much demolished; though the river has not yet forfeited the character given of it by Spenser in his Fairy Queen:

“The pleasant Bandon, crown'd with many a wood.”

Campbell's Political Survey of Great Britain, &c. Smith's Cork. Beaufort's Memoir.

BANDON-BRIDGE, or, as it is more commonly called, **BANDON**, a considerable market and post town of the county of Cork, province of Munster, Ireland, situated on both sides of the river Bandon, over which it has a bridge. It was one of the towns which owed their origin to the laudable exertions of Richard Boyle, the first, and frequently called the *great*, earl of Cork. He built it in the year 1610, in the midst of a waste bog and wood, which had been impassable, and inclosed it with walls, which were of great strength for that period. In 1613, he procured for it a charter of incorporation, in consequence of which it sent two members to the house of commons; and was one of the boroughs which occasioned so violent a debate at the meeting of parliament in that year. It was part of the policy of lord Cork, as appears from his letter to secretary Cook (quoted in Smith's Cork, vol. i. p. 236.), to admit none but Protestants to live in the town; which seems to have been considered a necessary support to the infant colony. The consequence of this was, that the inhabitants, being united among themselves, and all trained to arms, were very powerful, and took an active part in the civil wars which distracted Ireland, in the middle of the seventeenth century. After the restoration of Charles II. the exclusion was not very strictly observed, though it had been confirmed by a bye-law of the corporation; but the adherents of James II. under the earl of Clancarty, having destroyed the walls in 1689, and treated the Protestant inhabitants with severity, it was revived, and has been since, with few exceptions, strictly attended to. The wisdom and advantage of this exclusion have been often called in question, but the strongest objection to it certainly is, that it tends to keep alive that animosity which has been the bane of Ireland, and which all who study the true interests of the country will endeavour to appease. The inhabitants of Bandon have been generally industrious. For many years they carried on the manufactures of stuffs, camblets, and shags, very extensively, but these have of late declined. Ticken of superior quality, and coarse green linens 27 inches wide, called *witters*, are made in the town and neighbourhood; the latter of which is sent from Cork to London and Bristol. There are also some cotton manufacturers, who employ a great number of people. The town is chiefly the property of the duke of Devonshire, representative of the eldest branch of the Boyle family, and on account of the shortness of the leases, and the want of proper encouragement, it is in general ill built, the houses not at all corresponding to the wealth of the inhabitants. During the late war, Bandon became a great military station, being conveniently situated for sending

assistance to any part of the south-western coast at which it might be wanted, and a strong garrison is still contained there. The population is estimated at 12,000, and it sends a member to the imperial parliament. Its distance S.W. from Dublin is 136 Irish miles, and S.W. from Cork 17. N. lat. 51° 44'. W. long. about 8° 44'. South's Cork, &c.

BANDORA, the capital of Saltic island, and separated from Bombay island, on the Malabar coast of India, by a narrow channel, in N. lat. 19° 5'. E. long. 72° 30'.

BANDORA, in *Music*, an inferior kind of lute, for which the notes were written in the same kind of tablature as for the theorbo or great lute. See *LUTE*.

BANDT, in *Geography*, a small island in the German ocean, near the coast of East Frisland. N. lat. 53° 36'. E. long. 6° 33'.

BANDURI, **ANSELME**, in *Biography*, an antiquary of the eighteenth century, was a native of the republic of Ragusa, in Dalmatia, and a Benedictine monk. He studied at Florence, and having made rapid progress in the learned languages, he became a preceptor. Montfaucon employed him in 1700 to examine MSS. for his projected edition of Chrysostom's works; and for extending his acquaintance with ecclesiastical antiquities, Banduri, under the patronage of the grand duke of Tuscany, spent some years in the abbey of St. Germain in Paris. Here he was enabled to complete his valuable work, intitled, “*Imperium Orientalis, five, Antiquitates Constantinopolitane*,” and published at Paris, in 1711, in two volumes, folio. He also published at Paris, in 1718, fol. a collection of Roman medals, under the title of “*Nunismata Imperatorum Romanorum a Trajano Decio ad Paleologos Augustos*,” which was enriched and enlarged, and reprinted in 4to. at Hamburg, in 1719, by J. A. Fabricius. In 1724, Banduri was appointed librarian to the duke of Orleans, and he died at Paris in 1743. *Nouv. Dict. Histor.*

BANDUSIAN FOUNTAIN, in *Ancient Geography*, a famous spring of Sicily, celebrated by Horace in the thirteenth ode of his third book, placed by some at his Sabine farm; but incontrovertibly proved by the abbé Charpy, to be near Palazzo, in the principality of St. Germain. No shady groves now hang over its banks to shut out the burning mid-day sun; its gelid waters no longer tumble down the rocks in beautiful cascades; but choaked with dirt and lost in bogs, are forced to seek their way under ground to a vent at the foot of the hill. *Swinb. Travels*, vol. ii. p. 33.

BANDY-LEGS, in *Surgery*, are the distortion of the lower extremities, in any direction. This disease is usually occasioned by a defective ossification of the *Tibia* or leg-bone, which therefore is unable to sustain the weight of the body without yielding. See *DISTORTIONS*, and *MOLLITIES Ossium*.

BANE-BERRY, in *Botany*. See *ACTEA*.

BANEE, in *Geography*, a small island of France, near the English channel, about a league S. W. of Ushant.

BANER, **JONS**, in *Biography*, a famous general of Sweden, descended of an illustrious family, was born in 1601, and was so much distinguished by his proficiency in literature, that Gustavus Adolphus used to call him his learned general. In very early youth, he attracted, by his magnanimity, the notice of that monarch, who pronounced him formed for great events, and placed him in the army; and he soon signalized himself so much, that, under twenty years of age, he was employed in many critical enterprises, which required no less dexterity than bravery. After the death of Gustavus, he supported, as commander in chief, the lustre of the Swedish arms, by a series of victories, which raised his military character as high as that of any general of the age. He sustained this reputation undiminished till his death, at Halberstadt, on the 10th of May 1641, in the 40th year of his age. Baner, though not insensible of the glory he

had acquired by his actions, usually spoke of them with great modesty. He was accustomed to say, that he never formed an expedition, nor hazarded an action, without the most reasonable hopes of success. He was equally feared and beloved by the soldiers, and always inspired them with unbounded confidence. At the head of his troops, he acted solely from himself, and without dependence, and would rather have resigned the command, than have been directed in his military operations by the orders of the cabinet. He had the absolute disposal of all commissions, and established a regular order of promotion; he was humane to the vanquished enemy, cautious in not wantonly exposing his troops to action, and he blamed those generals who in sieges sacrifice the lives of their men to raise their own military character. Coxe's Travels in Poland, &c. vol. iv. p. 51.

BANFF, in *Geography*. See BAMFF.

BANGA, a town of Africa, in the country of Whidah, on the Slave coast.

BANGALORE, a town of Hindostan, in the Mysore country, situate in the centre of the peninsula, and having routes passing through it in every direction. It is, in itself, a place of great political importance, being a fortress of strength, and from situation, the bulwark of the Mysore country, towards Arcot. It is placed, by major Rennell, in N. lat. 13°. E. long. 77° 37' 10". This is the common point of union, in the centre of the peninsula, as Coimbatore is in the south-west, and Trichinopoly in the south-east.

BANGER, one of the principal places in the island of Belleisle, on the coast of France; and Palais is the other.

BANGIUS, PETER, in *Biography*, a Swedish divine, was born at Helsingberg, in 1633, and having studied at Upsal, travelled with a pupil through Sweden, Denmark, and the Netherlands. On his return, he was appointed professor of theology in the university of Abo in Finland, and filled the chair with credit 32 years. In 1682, he was appointed bishop of Wyburg, by Charles IX. of Sweden; and died in 1696. He took great pains to serve his country, by establishing schools; and promoting knowledge. He wrote in Latin an ecclesiastical Swedish history; a treatise on Sacred Chronology; a Commentary on the Hebrews, and other works.

BANGIUS, THOMAS, a learned Danish divine, of the university of Copenhagen, was born in 1630. He discharged, with great credit, the duties of the professorships of Hebrew, philosophy, and divinity; and was the author of several learned works. He died in 1661. Among his writings in Latin are various dissertations to elucidate the scriptures; "Philological Observations," printed in 8vo. at Copenhagen, in 1640; "An Exercise on the original Diversity of Languages, and on the Excellence of the Hebrew;" 8vo. 1634; and a "Hebrew Lexicon," 4to. 1641. Gen. Dict.

BANGLE EARS, in the *Manege*, an imperfection in a horse's ears, remedied in the following manner; place his ears in such a situation as they are wanted to stand; bind them with two small boards, so fast as not to stir; and then clip away the empty wrinkled skin close by the head.

BANGO, in *Geography*, a long shoal on the east coast of Africa, of variable breadth, but in some places about two leagues. See *Cape CORIENTES*.

BANGOR, a township of America, in Hancock county in the district of Maine, on the west side of Penobscot river, 25 miles from its mouth at Belfast Bay; 65 N.W. by W. from Machias; 63 N.E. from Hallowell; and 280 N.E. from Boston.

BANGOR, a small city of Carnarvonshire, North Wales,

consists principally of one straggling street which is situated in a narrow valley between two low ridges of slate rock, opening southward towards Snowdon, and terminating northwards about half a mile from the cathedral, in the beautiful bay of Beaumaris. This town is watered by the "Deva's wizard stream," whose opposite banks are connected now by a well-built bridge of five arches. Bangor is represented as the oldest episcopal see in Wales, but the present cathedral was not founded till the beginning of the fifteenth century. The choir was built by bishop Denn, in 1496, and the tower and nave by bishop Skivington, in 1532, as appears recorded over the western door. The former measures 140 feet by 60, and the length of the whole from east to west is 214 feet. This edifice contains many monuments of its bishops and other personages; but it possesses no extraordinary attractions either in its architecture or ornaments. The officers belonging to the cathedral, are a bishop, a dean, three archdeacons, a treasurer, two endowed prebends, a precentor, chancellor, and three canons; besides other inferior officers. The cathedral service is alternately in English and Welsh. Within the diocese are included the whole county of Anglesea, all Carnarvonshire, except Llysvaen, Eglwys Rose, and Llangwilerin, the greater half of Merionethshire, and the Deaneries of Dyffrynclwydd and Arwilly. This bishopric, though not large, nor rich, has suffered many defalcations. Among others it is said, that Owen Glendower destroyed the cathedral by fire, and bishop Bulkeley wasted and sold all the revenues, and reduced the see to great poverty. It is now valued in the king's books at 131l. 16s. 3d. The late and present bishops have made considerable alterations and improvements in the palace, its appendages, and in the town. Among the praiseworthy acts of the former, was the re-erection of a large free school under his superintendance. This city is governed by the bishop's steward, who holds his court here. Besides a weekly market on Friday, here are four fairs annually. Its number of houses is 304, and these contain 1770 inhabitants. Bangor is about fifteen miles west of Conway, and 253 from London. Half a mile from Bangor, on the shore of the bay, is Abererugin, or port Penrhyn, the grand depository of the slates that are procured from lord Penrhyn's quarries, at Dolawen. Great quantities of these slates are shipped for London, Liverpool, Bristol, and other large towns.

About two miles S. E. of Bangor, is Penrhyn-hall, the elegant mansion of lord Penrhyn. The improvements made by this nobleman in the commercial character of this part of the country, and by plantations, buildings, &c. are highly honourable to his liberality and judgment. There is a ferry into Anglesea, about two miles from this town, which is much more commodious than that of Conway.

BANGOR, *Bangor-Iscoed*, or *Bangor Benachorum*, is a small village in Flintshire, North Wales, remarkable for a handsome bridge over the river Dee, and the site of an extensive and rich monastery. Bede, and several of our historians, describe this place as very flourishing at the coming of St. Augustine; and most of them relate, that Ethelrith king of the Angles, advanced to Chester with a large army, and observing the monks praying for the success of their countrymen, he rushed upon them, and consigned 1200 to death. This abbey, according to Leland, stood in a fair valley close on the Dee; but when he visited the place, every vestige of the buildings was destroyed, and the site ploughed over. Some writers have confounded this with the Bangor in Carnarvonshire. It is probable that the latter derived its name and consequence from and after the destruction of the former.

BANGOR, a post town, and sea-port of the county of Down

Down, in the province of Ulster, in Ireland, situated on the south side of the bay of Carrickfergus; but though parliamentary aid was granted to improve its port, it has very little trade. An abbey was founded here in the sixth century, part of the ruins of which yet subsists. Near this town duke Schomberg landed with the English army, 13th August 1689. Distance N. from Dublin, 90 Irish miles. N. lat. $54^{\circ} 35'$. W. long. $5^{\circ} 33'$.

BANGUE, in the *Matrici Nobilia*, a species of opiate, in great use throughout the East for drowning cares, and inspiring joy.

This, by the Persians, is called *bang*; by the Arabs, *esfar*, corruptly *esfar* and *esfar*; by the Turks, *bang*, and vulgarly *bang*; by the European naturalists, *bangue* or *hange*. The Indians, says Acosta, eat the seed and leaves to increase their vigour, and to excite an appetite to their food. The nobles and chief military officers, when they are disposed to forget their toil, and to sleep in perfect ease and security, take of the powder of the seed and leaves, as much as they think sufficient; and add to it an *arcia*, or green Indian hazel-nut; with as much opium as they think fit, and eat them all together with sugar. If they desire to be entertained with variety of scenes, and images of things in their sleep, they add some of the choicest camphor, cloves, nutmegs, and mace. If they have a mind to be merry, witty, and to indulge their amours, they add ambergrise and musk, and make them all into an electary with sugar. It is by many affirmed that the seed and leaves promote lust; whence says J. Bauhine, it appears that this herb has no affinity with hemp, though it be very much like it; since hemp, according to Dioscorides, is of a hot and dry nature, and extinguishes amorous desires.

Ray, from whom this account is taken, says, he learned from sir Hans Sloane, that it is a different plant from hemp. It grows in Hindostan, and other parts of the East Indies, where it is principally in use. Among the Indians the seed is prepared among other meliorating and aromatic substances into an electary, which excites pleasing visions, and as some say, emboldens them to perform the most daring and atrocious deeds. See DATURA.

Bangue, in reality, is a *saccedatum* to wine, and obtained in those countries where Mahometanism is established; which prohibiting the use of that liquor absolutely, the poor Mussulmen are forced to have recourse to *suicidena*, to rouse their spirits. The principal are *opium*, and this *bangue*, which, says Sale (Prel. Disc. p. 124.), consists of the leaves of hemp in pills or conveve, and by the rigid Mahometans is esteemed unlawful, though not mentioned in the Koran, because it intoxicates and disturbs the understanding as wine does, and in a more extraordinary manner. It is, however, commonly used in the East, but they who addict themselves to the use of it, are generally looked upon as debauchees. According to the account given of this substance by Alexander Maurocordato, counsellor and physician to the Ottoman Porte, in a letter to Wedelius, bangue is prepared of the leaves of wild hemp, dried in the shade, then ground to powder, put into a pot, in which butter has been kept; set in an oven till it begin to torrefy; then taken out, and pulverized again; and thus to be used in the quantity of as much, at a time, as will lie on the point of a knife. As to the opinion among the Europeans, that the Turks prepare themselves for battle by a dose of bangue, which rouses their courage, and impels them with ardour to certain death, Dr. Maurocordato assures us, that it is a popular error. The Turks think they are then going to receive the crown of martyrdom; and would not, for any consideration, forfeit the merit of it, which they would do by eating the bangue, which is held to be un-

lawful by their apostle, among other things which intoxicate.

BANGUEY, in *Geography*, an island of the Indian ocean, at the northern extremity of Borneo, not far from Balabac, the most south western of the Philippines. N. lat. $7^{\circ} 12'$. E. long. $117^{\circ} 25'$.

BANGUEY Peak lies in the peninsula of Malacca. N. lat. $7^{\circ} 18'$. E. long. $117^{\circ} 17' 30''$.

BANHAS, PADRO DOS, a small island in the bank, north of Madagascar, and near the *Islands* of the *Islands* of the Admirants, in about S. lat. $5^{\circ} 37'$, and E. long. $50^{\circ} 20'$.

BANHOS, PADRO DOS, a small island formed by a sandbank, east of the last island, as far as S. lat. $6^{\circ} 50'$. E. long. $50^{\circ} 20'$.

BANI, a small district of Africa, in the country of Calabar, containing nine or ten villages.

BANI, a town of Italy, in the kingdom of Naples, and province of Capitanata, ten miles south of Troia.

BANIA, a river of Croatia, which runs into the Ledia.

BANIAC, a small island on the west coast of Sumatra, in about N. lat. $1^{\circ} 40'$. E. long. $107^{\circ} 50'$.

BANJALUKA, or BAGWALUKA, a considerable town of European Turkey, in Bosnia, the residence of a pacha, seated near the river Setina, on the frontiers of Dalmatia, 144 miles W. of Belgrad. It is supposed to contain 18,000 persons. N. lat. $44^{\circ} 20'$. E. long. $18^{\circ} 20'$.

BANIAN-DAYS, in *Morm. Language*, a cant term among sailors, to signify those days in which they have no flesh meat. It seems to be derived from the practice of the people mentioned in the article BANIANs.

BANIAN Tree, in *Botany*. See FIGUS.

BANIANA, in *Ancient Geography*, a town of Hispania Betica, in the country of the Turduli. Ptolemy.

BANIANS, a religious sect in the country of the Mogul who believe a *metempsychosis*, and will therefore eat no living creature, nor even kill noxious animals, but endeavour to release them, if they see them in the hands of others.

The *Banians* are said to be so fearful of having communication with other nations, that they break their cups, if one of a different religion have drank out of them, or even touched them; and empty the water out of a pond where he has washed himself. It is added, that if they happen to touch one another, they must wash and purify themselves before they eat, or enter their own houses. They carry hanging at their necks, a stone called *tanleran*, as big as an egg, and perforated in the middle, through which run three strings: the stone, they say, represents their great god, and upon this account, they have great respect shewn them by all the Indians.

In a more general sense, the appellation of Banians comprehends all the idolaters of India, as contradistinguished from the Mahometans; but in a more restricted and peculiar sense, it is appropriated to one of the four principal casts, into which the Indians are commonly divided; the other three being the Bramins or priests, the Rajaputs or men of the sword, and the armans and labourers. See HINDOES.

The proper *Banians* are called, in the SHASTER, or book of their law, by the name of *shudra*, under which are comprehended all who live after the manner of merchants, or that deal and traffick for others, as brokers; exclusive of the mechanics, or artificers, who make another cast, called *seife*. Their name in the Brahma language, in which their law is written, signifies "an innocent and harmless" people; and such they really are; for they cannot bear to see a fly, worm, or any other living creature hurt; and if they receive a blow, they take it meekly and patiently. These Banians have no peculiar sect or religion, unless it

be, that two of the eight general precepts given by the legislator, Brenaw to the Indian nation, are, on account of the profession of the Banians, supposed more immediately to relate to them, viz. those which enjoin veracity in their words and dealings, and avoiding all practices of circumvention in buying and selling.

The Banians and the Chinese are the greatest traders in the Indies, to whom must also be added the Jews and Armenians who are greatly dispersed over those parts. But the most considerable trade is carried on by the Banians, in the whole peninsula on this side the Ganges. They are extremely skilful and cunning in commerce. Most of them follow brokerage, and most of the brokers of the English, Dutch, and French companies are of that nation. They are deemed, in general, very honest, and have almost constantly in their hands the stock and cash of those companies.

They are likewise bankers; and there are few places in the East Indies for which they cannot furnish bills of exchange. They have also a sort of standing cash or bank where persons may deposit their money, and take it out again whenever they please.

Their form of contract, in buying and selling, is remarkable; being done in the profoundest silence, only by touching each others fingers: the buyer loosening his *pamrin*, or girdle, spreads it on his knee; and both he and the seller having their hands underneath, by the intercourse of the fingers, mark the price of pounds, shillings, &c. demanded, offered, and at length agreed on. When the seller takes the buyer's whole hand, it denotes a thousand, and, as many times as he squeezes it as many thousand pagods, or roupees, according to the species in question, are demanded: when he only takes the five fingers, it denotes five hundred, and when only one, one hundred; taking only half a finger, to the second joint, denotes fifty; the small end of the finger, to the first joint, stands for ten. See CEURAWATH.

Their children are sometimes accustomed to trade, and to imitate the gentleness of manners, which distinguishes this class of persons. Those of the Banians, who have slaves, treat them with great humanity. Their manner of living is very frugal, and they never depart from it, except when they fettle their children; on which occasion, they spend a sum amounting to no less than 12,500*l.* Their women are also distinguished by their simplicity of manners. They hold the nuptial tie in great veneration; and never allow themselves the least intercourse with strangers. Their husbands will not be satisfied without this reserve; alleging against every kind of familiarity between the sexes this proverb; "if you bring butter too near the fire, you can hardly keep it from melting."

BANIAS, in *Geography*, a town of Syria, fifty miles S. W. of Damascus.

BANIER, ANTOINY, in *Biography*, a French abbé, was a native of Clermont, in Auvergne, who completed his education at Paris. Having been employed in classical instruction, he directed his particular attention to the subject of ancient mythology, and published in two volumes, 12mo., "An Historical Explanation of the Fables of Antiquity." This work gained him the reputation of being a writer of taste and erudition; and 1714, he was admitted into the Academy of Inscriptions and Belles Lettres. In 1715, his treatise, designed to trace the fables of the ancients to historical facts as their true origin, was much enlarged and published in the form of dialogue. The same subject was pursued by the author in several dissertations communicated to the academy of which he was a member, and published in its Memoirs. With a view to the same subject, he presented the public with the result of his researches during the

last ten years of his life, first in his "Translation of the Metamorphoses of Ovid," with historical remarks and illustrations, and the plates of Picart, published at Amsterdam, in folio, in 1732, and reprinted in 1738 at Paris, in two volumes, 4to; and afterwards in a work, intitled, "Mythology, or the Fables explained by History," printed in 4to, and also in 12mo. at Paris, in 1740, translated into English, and printed at London in 1741, in 4 vols. 8vo. Banier died in November 1741, aged 69 years. He published an improved edition of Marville's "Mélanges d'Histoire et de la Littérature," and had a great share in the new edition of Picart's "General History of Religious Ceremonies," published in 1741. *Nouv. Dict. Hist.*

BANJERMASSING, or BENDLER MASSIN of M.d'Anville, in *Geography*, a town and district on the fourth side of the island of Borneo; the chief product and trade of which are pepper. The factory of the Dutch lies in S. lat. 3°. They have here a small fort, where a junior merchant, as resident, with about 25 or 30 soldiers, are stationed. The object of this establishment is chiefly the collection or purchase of the pepper and rough diamonds produced in the country. The resident is allowed five per cent on the pepper. The contract with the king obliges him to deliver 600,000 pounds at three shivers per pound; and this is the only article which induces the company to retain this possession; for the profits on the rough diamonds, gold, wax, canes, and sago, would not be sufficient to make good the charges. Banjermassing is of no importance to the company as a source of revenue, for they do not possess a foot of land without their fort, and are obliged to be constantly on their guard against the insidious attacks of the natives. The charges of this establishment in 1779 were about 1100*l.* sterling, which, together with those of conveying the pepper to Batavia, are scarcely covered by the profits accruing from this scanty trade. The river Banjar, called Biajos by d'Anville, flows from the centre of the country almost due south, and forms the harbour of the town; and on this river is experienced a difference of twelve feet in the rise and fall of the tide. The Biajos, as they are denominated, come down this river to the port in rude boats, with gold dust, and other articles, among which are diamonds; the Moors called Banjareens being the factors. These Biajos are tattooed blue, with a small wrapper about the loins. The chiefs extract one or two of the fore-teeth, substituting others of gold; and fringes of the teeth of tigers, which abound in the island, a real badge of knighthood or of courage, are worn round the neck.

BANILLIA, in the *Materia Medica*, a name used by some for the *vanilla*, or vanilloes, used in making the scented chocolate.

BANISHMENT, EXILE, in *Law*, among us, is of two kinds: the one voluntary, and upon oath; the other by compulsion, for some offence or crime.

The former, properly called *abjuration*, was abolished by stat. 21. Jac. I. c. 28.; and has now ceased, 2 Inst. 629; the latter is enjoined by judgment of parliament. Yet outlawing and transportation may be also considered as a species of exile.

However, no power on earth, except the authority of parliament, can send any subject of England out of the land against his will; no, not even a criminal. For exile and transportation are punishments at present unknown to the common law; and whenever the latter is now inflicted, it is either by the choice of the criminal himself to escape a capital punishment, or else by the express direction of some modern act of parliament. To this purpose Magna Charta declares (c. 29.) that no freeman shall be banished, unless by the judgment of his peers, or by the law of the land. And

by the *habeas corpus act* (31 Car. II. c. 2.), it is enacted, that no subject of this realm, who is an inhabitant of England, Wales, or Berwick, shall be sent prisoner into Scotland, Ireland, Jersey, or Guernsey, or places beyond the seas, where they cannot have the full benefit and protection of the common law: but that all such imprisonments shall be illegal; that the person who shall dare to commit another contrary to this law, shall be disabled from bearing any office, shall incur the penalty of a præmure, and be incapable of receiving the king's pardon; and the party suffering shall also have his private action against the person committing, and all his aiders, advisers, and abettors, and shall recover treble costs besides his damages, which no jury shall assess at less than 500*l.* Blackit. Com. vol. i. p. 137.

BANISTER, JOHN, in *Biography*. was educated at Oxford. In 1573, having taken a bachelor's degree, he obtained a licence to practise physic. He then went to Nottingham, and professing both medicine and surgery, "was wonderfully followed (Wood says) by all sorts of people, for his happy practice in those arts." Banister published several works, of which the following are the titles: "A needful, new, and necessary Treatise of Chirurgery, briefly comprehending the general and particular Curation of Ulcers, with certain Experiments of his own Invention," London, 1575, 8vo. It is dedicated to Tho. Stanhope, esq. high sheriff of Nottinghamshire. "The History of Man, suckled from the Sap of the most approved Anatomists," nine books. fol. Lond. 1578; decorated. Douglas says, with anatomical engravings, copied from Vesalins, but miserably executed. "Compendious Chirurgery, gathered and translated, especially out of Wecker," Lond. 1585, 12mo. This is not a mere translation, the work being corrected and much improved by Banister. "Antidotary Chirurgical," containing variety of all sorts of medicines, Lond. 1589, 8vo. In 1633, several years after his death, his chirurgical works were published together in six books, in 4to. The Antidotary was dedicated to the earl of Warwick, by whom he appears to have been patronised. Wood's *Athenæ Oxon.* Aikin's *Biograph. Mem.*

BANISTER, Richard, was in great credit in the end of the sixteenth and beginning of the seventeenth century, for his skill in surgery, which he practised at Stamford in Lincolnshire. His knowledge in the art he learned of his near kinsman, John Banister, by whom he had been educated. "Sitting at the feet," he says, "of a Gamaliel in that art, let his name (he adds) be as a precious ointment poured out; for he was one to whom malice itself could do no mischief, nor hatred hurt." He continued in the general practice of surgery several years. "At length," he says, "I left the greatest mass of that unmeasurable mystery, and confined myself to the cure of the eyes, of the hare lip, the wry neck, and to assist the hearing by an instrument." But his principal object was relieving the blind; to perfect himself in this art, he appears to have associated with Henry Blackbourne, Robert Hall of Worcester, master Velder, Surflet, and Barnabie, of Fenny Stanton, Lynn, and Peterborough, all famed for their skill in couching and performing their operations on the eyes. Following their example, he visited many of the principal cities in the kingdom, particularly London, which place he visited spring and autumn for several years. It appears to have been his custom to procure certificates of the cures he performed at each place. "I can shew," he says, "that in the year 1609, I made, with the help of God, twenty-four blind people see in the city of Norwich; and I came thither again in 1611, and all of them had their sight: for confirmation of which, I had a certificate from the mayor

and alderman, with the city seal annexed." A similar certificate he obtained from Sir Wm. Cockaine, lord mayor of London in the year 1621, which appears to have been the last time of his coming thither. "But now," he says, "I know it is not long to the period of my days, so I mean to rest at home the small remnant that God hath allotted to me." He promises, however, to continue to assist those who visit him at his house. The time of his death is not known.

In 1622, he published "A Treatise of one hundred and thirteen diseases of the eyes and eye-lids: the second time published with some profitable additions of certain principles and experiments by Richard Banister, master in chyrurgery, oculist, and practitioner in physick," 12mo. The book is not paged. The part added by Banister seems to be a final treatise at the beginning of the volume, which he calls "Banister's Breviary of the Eyes." He here complains of the number of ignorant persons, and among them many women, who interfered in the art, to the hurt of the people. This part is interspersed with poetical effusions, in which he laughs at some pretended cures performed by drinking and washing the eyes with the waters of the Malvern and other springs.

"So many folks unto the town did run
For water, that alewives were half undone.
At first, when this news unto me was told,
I daunted was, it touch'd my freehold.
I dwelt from thence, at least some twenty miles,
Yet there my patients went o'er fields and hyles."
He had the satisfaction, however, to see them come back,
"Their bodies wear'd, and their griefs made worse,
And eas'd and purg'd only in the purse."

The treatise which gives the general title to the volume, and of which Banister has with most people the credit of being the author, was written originally in French by Jacques Guillemeau, translated into English by an anonymous writer, and dedicated to John Banister. Wood's *Athenæ Oxon.* Aikin's *Biog. Mem.*

BANISTERIA, in *Botany*, so named by Dr. Houtton in memory of the Rev. John Banister, a curious botanist, who lost his life in the search after plants in Virginia. Linn. gen. n. 573. Reich. 622. Schreb. 780. Cavanilles, t. 243, 258. Gert. t. 116. Clafs. *decandria trigynia; monadelphia* Cav. Nat. Order, *tribilata; malpighia*. Jusl. Gen. Char. *Cal.* perianth, five parted (four, seldom five, Cavan.) very small, stiff underneath with tubercles, permanent; two melliferous glands under each division of the calyx, except one; and they are therefore eight in number. *Cor.* petals five, orbiculate, very large, spreading, crenate (serrate C.); claws oblong, linear. *Stam.* filaments ten, very small, coalescing at bottom: anthers simple. *Pist.* germs three, winged, coalescent: styles three, simple: stigmas obtuse (enlarged into a leaflet, Cav.) *Per.* capsules three, running out into a long wing, one-celled, marked at the sides with small appendices, not gaping. *Seeds* solitary, covered, toothed on the lateral edge. *Obs.* The flower, especially the glands of the calyx, shew the affinity between this and malpighia. It differs however in the leafy stigmas and winged fruit. *B. leona* has ten, the rest have eight glands. Cav.

Ess. Char. *Cal.* five-parted, with melliferous pores at the base on the outside. *Per.* roundish with claws; stigmas leaf-shaped; seeds three, winged with membranes.

Species, 1. *B. angulifolia*. Reich. 2. 371. Cavan. diss. 426, t. 252. Lamarek. Dict. n. 1. Aublet. Guian. 2. 466. Acer scandens, fol. anguloso. Plum. Spec. 18. Clematis anguloso folio, aceris fructu. Plum. Amer. 77. t. 92. "Leaves tri-nate-angular." Stem twining, with opposite branches, thickened at the base; leaves cordate, angular, terminating

at top in a short dagger point, green above, whitish beneath, nearly equal to the petioles, on which and near the leaf are two opposite glands; without stipules; flowers in opposite axillary umbels; common peduncle elongated; rays five to seven, an inch long, jointed, with two short, opposite bracts; at the insertion of the rays are two small suborbiculate leaves; corolla sulphur-coloured. A native of Dominique, Hispaniola, &c. 2. *B. furcata*. Lam. Dict. n. 2. Plum. Spec. 18. ic. 15. Mf. t. 2. Acer. Durr. Amer. t. 15. "Leaves ovate; spikes lateral; seeds erect." Stem strong and woody, dividing into many opposite and twining branches; leaves ovate, on short petioles; there are five or six pairs of branches, nearly of the same size with those of the common acacia, but whitish on their under side; flowers axillary, in a kind of spike; petals purplish, short; third germ often abortive, whence Plumier says that the fruit is bicarpular and two winged; and Miller, that the greater number of species have only two styles. A native of the Caribbee islands, sent to Miller from Campeachy, and cultivated by him in 1759. 3. *B. laurifolia*. Lamarek. Dict. n. 3. Acer scand. fol. laurinis. Sloan. Jam. 2. 26. Plum. Spec. 18. ic. 14. "Leaves ovate-oblong, rigid; racemes terminal." Stem shrubby, climbing, with loose, reflex, diverging, roundish, rugged branches; leaves petioled, ovate-lanceolate, acute, entire, nerved, smooth; racemes paniced; peduncles commonly one-flowered, short, yellow; leaflets at the base of the peduncles two, minute, tomentose; calyx five-leaved; petals spatulate; anthers elliptic; germ three-cornered, twisted at the tip; styles subulate, short; stigmas dilated, one of the three capsules usually abortive; wings three or four times longer than the capsules. A native of Jamaica and Hispaniola. 4. *B. longifolia*. "Leaves oblong, acuminate, rigid, shining, panicle terminating; branches spreading very much." A native of the West Indies. 5. *B. benghalensis*. "Leaves ovate-oblong, acuminate; racemes lateral; seeds spreading." This species recedes from the genus, it has only one style, and the capsule has four wings. It has strong woody stalks, twining about trees which grow near it, and rises twenty feet high. A native of the East and West Indies. 6. *B. dichotoma*. *B. convolvulifolia*. Cavan. diss. 428. t. 236. Lamarek. Dict. n. 6. "Leaves ovate; branches dichotomous." Plumier first observed it in the island of Martinice. 7. *B. fulgens*. "Leaves subovate, tomentose underneath; racemes brachiate; peduncles umbelled." Its slender winding stalks rise five or six feet high; the flowers grow in a round bunch at the extremity of the branches, of a brownish yellow colour; the seeds are smaller, and have narrower wings than in the third species. A native of Jamaica and Barbadoes. 8. *B. brachyata*. "Leaves subovate; branches brachiate; seeds narrower within." Very like the foregoing; but the leaves more blunt; sending out many branches, dividing into others, and yielding tendrils which fasten to neighbouring trees, and mounting to a great height; the flowers, in loose clusters at the ends of the branches, are first of a gold colour, and fade to a scarlet, succeeded by slender thin seeds. A native of Carthage. 9. *B. aculeata*. "Leaves pinnate; leaflets oblong, obtuse; flowers spiked; stem branching, prickly." Climbing stalks, dividing into many branches with long winged leaves, composed of about twenty pair of small blunt pinnæ, each having a deep furrow on the under side; the flowers grow on loose spikes at the end of the branches, and are succeeded by single seeds, as large as those of the greater maple. A native of Tolu. 10. *B. carulea*. Acer. Plum. Mf. 2. t. 109. Spec. 18. "Branches tubercled; leaves ovate-acute, coriaceous; racemes axillary." A native of Jamaica and Dominique. 11. *B. nitida*. "Leaves ovate-oblong, quite entire, shining beneath; panicle termi-

nating leafy." A native of Brazil, where it was found by Commerçon. 12. *B. bryifolia*. "Branches tubercled; leaves ovate-acute, with a green tap on the lower surface; wings very long." Found by Commerçon near Rio-Janeiro in Brazil. 13. *B. muricata*. "Leaves ovate-acute, tomentose beneath; racemes axillary; capsules muricate." A native of Peru, where it was found by Joseph de Jussieu. 14. *B. Leona*. "Branches tubercled; leaves ovate-acuminate, coriaceous; flowers paniced." It varies with more elongated leaves. A native of America, and found by Smeathman at Sierra Leona in Africa, whither perhaps it has been transported. 15. *B. ferruginea*. "Leaves ovate-acuminate, ferruginous beneath; flowers paniced; bracts imbricate." A native of Rio-Janeiro, near St. Sebastian, in Brazil, found there by Commerçon. 16. *B. emarginata*. "Leaves ovate, subcordate, emarginate-cuspidate at the end, tomentose on the lower surface, flowers raceme-corymbed." A native of America. 17. *B. Guayana*. "Leaves ovate, tomentose beneath, flowers in corymbs, seeds erect." A shrub, six feet high, putting out many tomentose twining branches, by which it climbs up trees. A native of Guiana, on the borders of meadows, flowering in August, observed there by Aublet. 18. *B. sinuatifolia*. "Leaves ovate, acuminate, flowers in corymbs, yellow, wings gradually widening." A shrub with a trunk five feet high, putting forth many climbing, twining branches. A native of Guiana, on trees, by the sides of meadows and fields, flowering and fruiting in August, observed there by Aublet. 19. *B. orbiculata*. "Stem twining; leaves orbiculate, beneath tomentose and silky; petioles biglandular." A native of Jamaica, Guadaloupe, and St. Domingo. Cavanilles attributes to this the same synonyms of Sloane and Browne, which Linnaeus has given to *B. fulgens*. 20. *B. ciliata*. "Leaves cordate-roundish, eared, smooth, ciliate." A native of Brazil, where it was found by Dombey. 21. *B. auriculata*. "Stem twining, leaves subflagittate, smooth, with rounded lobes, flowers in umbels." A native of Rio Janeiro, found there by Commerçon. 22. *B. ovata*. "Stem twining, leaves ovate, acute, quite entire, flowers in umbels, involucre stipuled." A native of the island of Dominique, where it was found by Desportes and Surian. 23. *B. palmata*. "Stem twining, leaves palmate, tomentose beneath, petioles biglandular." A native of St. Domingo, found there by Desportes. 24. *B. sagittata*. "Stem twining, leaves sagittate, large, tomentose, petioles biglandular." A native of St. Domingo, found there by Desportes.

The species of this genus are all inhabitants of very hot climates, chiefly of America, from Brazil to Louisiana, particularly the islands. They are shrubs, mostly with twining stems, adorning the woods with the beauty of their flowers, and the variety of their opposite leaves. Plumier discovered four sorts; and for the rest, we are obliged to Aublet, Commerçon, and other modern travellers.

Propagation and Culture. These plants, being natives of hot countries, cannot be preserved in England, unless they are kept in a bark-love. They are propagated by seeds, procured from the countries where they grow, naturally gathered when fully ripe, and brought to England in sand or earth. When they arrive, they should be sown immediately in pots, and if it be autumn, or winter, the pots should be plunged into a hot-bed or tanner's bark, and secured from frost and wet, till spring, when they must be removed to a fresh hot-bed, which will bring up the plants; when the plants come up, let them be put into separate pots, filled with light earth, and plunged into the bark-bed, after which they must be treated like other tender plants from the same countries. Martyn's Miller.

BANISTERIA. See GOUANIA.

BANK, in *Commerce*, is a denomination given to certain societies or communities, who take on them the charge of the money of private persons to improve it, or keep it secure; or it is a common repository, where many persons agree to keep their cash, to be always ready at their call, or direction. The word *bank* in this sense comes from the Italian *banca*, formed of the Spanish *banco*, a bench, whereon the ancient money-changers sat in the public markets; or, as others think, a table whereon they told their money; for the Spanish *banco* signifies a table, as well as a bench; as among the Greeks the word $\tauραπεζα$ signified a bench, as well as a table, whence the word $\tauραπεζιτης$ for a *banker*. Accordingly the institution of banks commenced in Italy, where the Lombard Jews kept benches in the market-places for the exchange of money and bills. Mr. John Law, indeed, in his treatise, intitled, "Money and Trade considered," ascribes the invention of banks to Sweden; alleging that the bulk of their money being copper, rendered it inconvenient; and in order to remedy this, a bank was set up, where the money might be pledged, and paper credit given to the value, which passed in payments, and facilitated trade. But this opinion, says Anderson (*Hist. Comm.* vol. i. p. 476.), is so far from being barely probable, that it is in a manner past all doubt, that the five cities of Italy were, in very early times, the inventors of banks (lumber-houses, or lombard-houses) and bills of exchange, long before the countries on the north extremity of Europe knew any thing of commerce, which Sweden knew least and latest of all the rest.

It cannot be doubted but that the beginning of traffic was by exchanging one commodity for another, as men could best suit each others occasions. But the necessities of men being so various and different, in respect to the quantity and quality of requisites, money was instituted as the most convenient medium for commerce, whereby people might procure whatsoever they stood in need of, in quantities according to their exigencies.

This changed the term of bartering into that of buying and selling; yet all trading at length results into a general barter. For he who sells any thing to receive money for it, purchases what he requires with the same money. Money then becoming the principal engine for circulating the bulk of commerce, its application to trade is proper to be considered.

Money is used in the minuter kinds of dealings, as retailing, &c. when it is commuted for all kinds of labour, and to furnish the necessary provisions for daily use. This requires its being divided into the smallest denominations of the pieces, as into shillings and pence; so that this way of dealing is not capable of being transacted by bills and assignments.

Money is also employed in the more extensive and wholesale way of trade, wherein large sums are negotiated; and this occasions frequent payments from one tradesman to another. In which payments, although strictly speaking ready cash be required as often as contracts are made, yet as commerce in general consists in the mutual dealings and transactions of many traders, it may often so fall out, by means of interchangeable debts and credits, that divers traders may satisfy each others occasions, without making any payments in specie, by transferring their debts to each other.

But when such mutual conveniences do not occur, traders usually receive their money in specie, and to pay it from one to the other. Yet this way of payment is attended with many inconveniences, as trouble in counting the money, hazard in securing it from the attempts of robbers.

and loss from trusting it with unfaithful servants; for the prevention of all which, cities of large commerce have very naturally introduced the use of banks.

Of these banks some are *public*, consisting of a company of moneyed men, who, being duly established and incorporated by the laws of their country, agree to deposit a considerable fund or joint stock, to be employed in various ways for the use of the society; or *private*, being such as are set up by private persons or partnerships, who traffic in the same way upon their own single stock or credit. Of the former sort of banks, several have been established in the principal trading cities of Europe, as in Venice, Genoa, London, Edinburgh, Amsterdam, Hamburgh, Paris, &c. The most ancient of these is the bank of Venice.

BANK, or **BANCO**, of *Venice*, commonly called *banco del giraz*, was established in the middle of the twelfth century, or as Anderson suggests (*Hist. Com.* vol. i. p. 84.), A.D. 1157, though some have dated its establishment in 1176, or somewhat later. It is properly a board of public credit and interest, or a general and perpetual purse for all merchants and traders, established by a solemn edict of the commonwealth, which enacts, that all payments of wholesale merchandise, and letters of exchange, shall be in banco, or bank notes; and that all debtors and creditors shall be obliged, the one to carry their money to the bank, the other to receive their payments at banco; so that payments are performed by a simple transfer from the one to the other; he who was before creditor on the bank books, becoming debtor as soon as he has resigned his right to another, who is entered down as creditor in his place; so that the parties only change name, without any effective payment being made. Indeed there are sometimes actual payments made, especially in matters of retail, and when foreigners are disposed to have ready money to carry off in specie; or when particular traders choose to have a stock by them to negotiate in bills of exchange, &c. The necessity of these effective payments has given occasion to the opening a fund of ready money; which is found so far from diminishing the stock, that this liberty of withdrawing money at pleasure rather augments it. By means of this bank, the republic, without encroaching on the freedom of commerce, or without paying any interest, is mistress of 5,000,000 ducats, to which the capital of the bank is limited, to be in readiness on any pressing occasion; the republic being security for the capital. The original fund of this bank was two millions of ducats. In one of its wars with the Turks, the state became security to pay the money lodged in it, which they had been under a necessity of using in that exigency. Its agio, in process of time, arose so high as to be 30 per cent. better than current money, although the state by several edicts endeavoured to keep it lower. Its capital was afterwards made double the original sum; and the state, in another exigency, made free with that increased capital. In after times the state enacted, that bank money, or the agio of the bank, should never exceed 20 per cent. advance, as it still remains to this day.

The constitution of this bank was originally founded on such just principles, that it has served as a model in the establishment of banks in other countries, and the administration of its affairs has been conducted with so much integrity, that its credit has never been shaken; and it has been of infinite benefit to the state. For adjusting and balancing all their accounts in banking, they shut their books four times in every year, for three weeks at each period. Accordingly, Venice may boast of having given the first example to Europe of an establishment altogether unknown

to the ancients, and which is the pride of the modern commercial system.

BANK of England, was first established in the year 1694, partly for the convenience of commerce, and partly also for the emolument of the proprietors; and it is the greatest bank of circulation in Europe. The scheme was projected by Mr. W. Paterfon, a merchant, and debated for a long while in the privy council, till at length, by an act of 5 & 6 William & Mary, cap. 20. it was enacted, that their majesties might grant a commission to take particular subscriptions for 1,200,000*l.* of any persons, natives or foreigners, whom their majesties were hereby empowered to incorporate with a yearly allowance of 100,000*l.* viz. 96,000*l.* or 8 per cent. for interest till redeemed, and 4000*l.* to be allowed the intended bank for charges of management. The corporation was to have the name of "The governor and company of the bank of England;" their said fund to be redeemable upon a year's notice, after the 1st of August 1705, and payment of the principal, and then the corporation to cease. The company was enabled by this act to purchase lands, &c. unlimitedly, and to enjoy the other usual powers of corporations; their stock was to be transferrable. They were restricted from borrowing more than 1,200,000*l.* except on parliament funds, and from trading in any merchandise, except in bills of exchange, and in bullion, and in the sale of such goods as were the produce of lands purchased by the corporation: and all bills obligatory under the seal of the said corporation, were made assignable by indorsement. The charter of incorporation was executed July 27, 1694; which directs, that there be a governor, deputy-governor, and twenty-four directors; and specifies the qualifications of voters and of directors; together with other regulations, which have been farther amended and enlarged by subsequent statutes.

In 1697, the bank was allowed to enlarge its capital stock, by an engraftment of 1,001,171*l.* 10*s.* Its whole capital stock, therefore, amounted at this time to 2,201,171*l.* 10*s.* This engraftment is said to have been for the support of public credit. In 1696, tallies had been at 40, and 50, and 60 per cent. discount, and bank notes at 20 per cent. During the great recoinage of silver, which was going on at this time, the bank had thought proper to discontinue the payment of its notes, which necessarily occasioned their discredit. By this engrafting act, as it was called, the capital stock of the bank was to be exempted from any tax; no act of the corporation, nor of its court of directors, nor sub-committees, should subject the particular share of any member to forfeiture; but these shares were subject to the payment of all just debts contracted by the corporation; and it was made felony to counterfeit the common seal of the bank, affixed to their sealed bills, or to alter or erase any sum in, or any indorsement on their sealed notes, signed by order of the said governor and company, or to forge or counterfeit the said bills or notes. This act was judiciously framed for the restoration of public credit; and it served to effect two points; viz. the rescue of the exchequer tallies and orders from the stock-jobbing harpies by engrafting them into this company, and also by cancelling the bank notes, also engrafted, which had been at 20 per cent. discount; because the government had been greatly deficient in their payments to the bank; and a good interest was secured to the proprietors of the increased capital. By stat. 6 Anne c. 22. it was enacted, for securing the credit of the bank of England, that no other banking company in England shall consist of more than six persons, empowered to issue bills or notes payable on demand, or for any time less than six months, which is the only exclusive privilege belonging to the bank. In pur-

suance of the 7th Anne. c. 7. the bank advanced and paid into the exchequer the sum of 400,000*l.*; making in all the sum of 1,600,000*l.* which it had advanced upon its original annuity of 96,000*l.* interest, and 4000*l.* for expence of management. In pursuance of the same act, the bank cancelled exchequer bills to the amount of 1,775,027*l.* 17*s.* 10½*d.* at 6 per cent. interest; it likewise undertook the circulation of 2,500,000*l.* of exchequer bills issued for the supply of the year; and it was at the same time allowed to take in subscriptions for doubling its capital. In 1709, therefore, the capital of the bank amounted to 4,402,343*l.*; and it had advanced to government the sum of 3,375,027*l.* 17*s.* 10½*d.* By a call of 15 per cent. towards the 400,000*l.* advanced to government, there was paid in and made flock 656,204*l.* 1*s.* 9*d.*; and by another call of 10 per cent. in 1710, 501,448*l.* 12*s.* 11*d.* In consequence of these two calls, the bank capital amounted to 5,559,995*l.* 14*s.* 8*d.* In consideration of the sum of 400,000*l.* advanced to government without interest, the exclusive privileges of the bank were prolonged to one year's notice, after the 1st of August 1722.

The convenience which government found in issuing exchequer bills by means of the bank, produced an agreement in 1713, when the company undertook to circulate new bills for raising 1,200,000*l.* towards the supplies, on having an allowance of 3 per cent. per annum, payable weekly, and a farther allowance of 8000*l.* per annum, payable quarterly. On this occasion, by 12 Anne, c. 11. the company obtained an additional term of 10 years to the period of their continuance as a corporation; so that they were not to be dissolved but upon twelve months notice after 1st of August 1742; and to enable them to fulfil their engagements, they were empowered to make a call for money upon the proprietors. In the following year, they first received the subscriptions to a loan for the public service, which had been hitherto usually taken at the exchequer; but the bank, being found more convenient for monied persons, has usually received them ever since.

In pursuance of stat 3 Geo. I. c. 7, 8, 9. in 1717, the bank delivered up two millions of exchequer bills to be cancelled; and it had, therefore, at this time, advanced to government 5,375,027*l.* 17*s.* 10½*d.* It was now agreed to reduce the interest from 6 to 5 per cent. In pursuance of the stat. 8 Geo. I. c. 21. in 1722, the bank purchased of the South Sea company stock to the amount of 4,000,000*l.*; and in this year, in consequence of the subscriptions which it had taken in for enabling it to make this purchase, its capital stock was increased by 3,400,000*l.* At this time, therefore, the bank had advanced to the public 9,375,027*l.* 17*s.* 10½*d.*; of which the sum of 1,600,000*l.* was entitled to 6 per cent. interest, till the 1st of August 1743; but the rest was to be reduced to 4 per cent. from and after Midsummer 1727; and the capital stock of the bank amounted only to 8,959,995*l.* 14*s.* 8*d.* It was upon this occasion, that the sum which the bank had advanced to the public, and for which it received interest, began first to exceed its capital stock, or the sum for which it paid a dividend to the proprietors of bank stock; or, in other words, that the bank began to have an undivided capital, over and above its divided one; and it has continued to have an undivided capital of the same kind ever since.

In 1728, the company of the bank advanced to government 1,750,000*l.* at 4 per cent. interest, without any power of enlarging their capital. In the following year, they advanced the farther sum of 1,250,000*l.* at 4 per cent. The capital due from government, after sundry redemptions, was 10,100,000*l.*; of which the sum of 1,000,000*l.* was re-

deemed

deemed in 1738, being part of the principal for exchequer bills cancelled in 1717.

In 1742, the company advanced a farther sum of 1,600,000*l.* towards the supply for that year, without receiving any additional allowance for interest or management; but they were empowered to enlarge their capital stock to the same amount; and by the act 15 Geo. II. c. 13. establishing this contract, by which the privileges of the bank were continued till one year's notice after the 1st of August 1764. it was declared, that the acts of 7 and 12 Anne, and all other acts for determining the corporation, should be void; and that the governor and company of the bank should remain a body corporate and politic for ever, subject to such restrictions and regulations as were contained in the acts and charters then in force. The whole sum, advanced on the original fund of 100,000*l.* per annum, thus became 3,200,000*l.* and the interest upon it from 1st of August 1742, 3 per cent. per annum.

By this act, persons forging, counterfeiting, or altering any bank note, bill of exchange, dividend warrant, or any bond or obligation under that company's seal, or any indorsement upon it, or knowingly uttering the same, shall suffer death without benefit of clergy. Moreover, the company's servants breaking their trust to the company, shall suffer death as a felon without benefit of clergy. It was also enacted, that when, at a court of directors of the bank, neither the governor nor deputy governor shall attend in two hours after the time appointed for business, then any 13 or more of the directors may chuse a chairman for the time, for the dispatch of business; and that such court shall be as valid as if either the governor or deputy governor had duly attended.

In consequence of the stat. 19 Geo. II. c. 6. in 1746, the bank agreed to deliver up to the treasury 986,800*l.* in exchequer bills; in lieu of which it was to have an annuity of 4 per cent for that sum, out of the fund for licencing spirituous liquors; and the bank was empowered to add the said 986,800*l.* to its capital stock, by taking in subscriptions for that purpose. Accordingly, at Michaelmas 1746, the whole debt due to the bank from the public was 11,686,800*l.* and its divided capital had been raised by different calls and subscriptions to 10,780,000*l.* The state of these sums has continued to be the same ever since.

In 1764, the company of the bank agreed to advance 1,000,000*l.* towards the supplies, in exchequer bills, to be repaid in 1766; and to pay into the exchequer 110,000*l.* without any repayment of the principal or allowance of interest for the same; in consideration of which, the term of their charter was extended to 1st of August 1786; and the dividend on the company's stock was raised at Michaelmas from $4\frac{1}{2}$ to 5 per cent. At Michaelmas 1767 it was raised to $5\frac{1}{2}$ per cent.

From a very early period after the establishment of the bank, it had been the practice of the company to assist government with money in anticipation of the land and malt taxes, and by making temporary advances on exchequer bills and other securities. In the year 1781, the sums thus lent to government amounted to upwards of eight millions, in addition to the permanent debt of 11,686,800*l.* An agreement was now entered into for the renewal of their charter, the term of which was extended to August 1812, on the company's engaging to advance 2,000,000*l.* on exchequer bills, at 3 per cent. interest, to be paid off within three years out of the sinking fund. In order to enable them to make this advance, a call of 8 per cent. on their capital was thought necessary, by which their former capital stock

of 10,780,000*l.* was increased to 11,642,400*l.* the sum on which they now divide. The dividend was also increased one half per cent. so that it now became 6 per cent. In consequence of this agreement, the total of their advances to government on the land and malt taxes, exchequer bills, and treasury bills, was increased, on the 25th of February 1782, to 9,991,678*l.* The amount of the bank-notes in circulation must of course be augmented by the increase of advances to government.

In consequence of large advances to government, the great exportation of coin and bullion to Germany and Ireland, and several concurring circumstances, which, at the commencement of the year 1797, produced an unusual demand of specie from different parts of the country on the banks, an order of the privy council was issued on the 26th of February, prohibiting the directors of the bank from making any cash in payment till the sense of parliament on the subject was obtained. This restriction was sanctioned by parliament; and a committee was appointed to examine the state of the bank, from whose report it appeared, that, on the 25th of February, after examining the outstanding claims against it with the corresponding assets, the amount of demands on the bank was 13,770,390; and that of assets, not including the sum of 11,686,800*l.* of permanent debt due by government, was 17,597,298*l.*; so that there was a surplus of 3,826,903*l.*

Soon after the meeting of parliament, in November following, the committee of secrecy, appointed to inquire into the expediency of continuing the restriction on the bank, reported, that the total amount of outstanding demands on the bank, on the 11th of November, was 17,578,910*l.* and the funds for discharging the same, exclusively of the permanent debt, 21,418,640*l.* leaving a balance in favour of the bank at that time of 3,839,730*l.* The report stated that the advances to government had been reduced to 4,258,140*l.* and that the cash and bullion in the bank had increased to more than five times the value at which they stood on the 25th of February 1797, when it was about 1,272,000*l.*

By this statement, the solvency and solidity of the bank were satisfactorily evinced; and, indeed, its stability must be coeval with that of the British government. All that it has advanced to the public must be lost before its creditors can sustain any loss. No other banking company in England can be established by act of parliament, or can consist of more than six members. It acts, not only as an ordinary bank, but as a great engine of state. It receives and pays the greater part of the annuities which are due to the creditors of the public (See *National Debt*, and *FUND*); it circulates exchequer bills; and it advances to government the annual amount of the land and malt taxes, which are frequently not paid up for some years. It likewise discounts the bills of merchants, and has, upon several different occasions, supported the credit of the principal houses, not only of England, but of Hamburgh and Holland. The business of the bank is under the direction of a governor, sub-governor, and 24 directors, who are elected annually by a general court; and it is transacted by a great number of subordinate clerks in different offices. The qualification of a director is 2000*l.* of a deputy-governor 3000*l.* and of a governor 4000*l.*; 500*l.* bank stock entitles the proprietor to vote at the general courts, provided he has been in possession of it six months.

The company may not improperly be denominated a trading company, and that which is peculiarly distinguished by the appellation of bank stock is a trading stock, the dividend of which, amounting to 11,642,400*l.* paid half-yearly, and now 7 per cent. accrues from the annual income of the com-

pany; and this arises from the interest received for the money advanced by the proprietors to the public, or the permanent debt of 11,686,800l.; from interest on the annual temporary advances; from the profits of their dealings in bullion, and of their discounts; from the interest of stock held by the company; from the sums allowed by government for the management of the annuities paid at the offices of the bank, such as, an allowance of 450l. per million for management of the public funds, and the allowance of 805l. 15 s. 10d. per million for receiving the contribution to loans, and from some other smaller articles.

The bank of England may be considered as the main spring of that complicated mechanism, by which the commercial payments of this country are transacted; and by which the comparatively small sum of money with which they are performed is kept in perpetual and regular circulation. The subordinate parts of this machine consist of about 70 private banking-houses in London, and about 386 banks dispersed over the country. By the joint operation of these various money-dealers, almost all bank payments, founded on commercial bargains, are ultimately settled in London, with the money which issues from the bank of England. This money consists, in ordinary times, partly of coin, and partly of bank notes. From its large capital and extensive issue of paper, that bank indirectly supplies the whole kingdom with as much gold as is required for circulation. Its notes are issued in loans, granted either for the accommodation of the public treasury, or for that of merchants by discount of their bills; and in consequence of a common agreement among the bankers, no notes of any private house are current in London. All the large payments of that metropolis are in this manner effected by the paper of the bank of England; and they are chiefly transacted by the private bankers, who, according to a conjectural estimate, make daily payments to the amount of four or five millions, and have probably in their hands a very large proportion of the whole of the notes circulating in the metropolis.

The following table will exhibit, at one view, the state of the cash and bullion, the average of bank notes in circulation, and also the discounts and advances to government during the several periods which it comprehends.

Date.	Cash and Bullion.	Average of Bank Notes in circulation.	Bills Discounted.	Average Advan. to Government.
1792. March	3,003,000	11,663,820	4,817,000	8,735,200
June	4,212,000	12,100,600	5,123,000	9,434,000
September	6,330,000	10,456,620	2,363,000	9,453,700
December	7,700,000	10,773,310	1,576,000	3,567,500
1794. March	8,603,000	11,180,720	2,338,000	3,494,100
June	8,203,000	10,306,480	3,263,000	7,723,700
September	8,006,000	10,243,940	2,500,000	6,773,700
December	7,763,000	10,927,070	1,587,000	7,543,100
1795. March	7,643,000	12,422,240	2,287,000	9,773,700
June	7,300,000	10,911,280	3,488,000	6,892,500
September	8,702,000	11,034,760	1,783,000	10,197,600
December	4,000,000	11,007,070	3,109,000	9,673,100
1796. March	2,972,000	10,224,150	2,820,000	7,211,000
June	2,532,000	9,770,200	3,700,000	11,209,300
September	2,532,000	9,720,440	3,332,000	9,901,100
December	2,500,000	6,453,710	3,790,000	9,511,400
1797. Feb. 26.	1,272,000	8,040,250	2,903,000	10,623,490

In the beginning of 1798, the bank advanced to government 3,000,000 on exchequer bills, and in the progress of the year a farther advance of 500,000l.; so that the total sum, advanced by the bank for the public service, and out-

standing on the 7th of December, was 6,777,739l. At a general court, held 14th of March 1799, it was agreed to advance to government 1,500,000l. on exchequer bills, and it was proposed to divide among the proprietors the 5 per cent. stock held by the company for the million subscribed to the loyalty-loan; and with this view to purchase 39,240l. of the same stock, to make up the sum held by them 1,164,240l. in order to make a dividend of 10l. 5 per cent. stock for every 100l. bank capital. Accordingly the transfer was made on the 11 of June.

In November following, a negotiation was entered into for renewing the term of the company's charter, although about 13 years of it remained. The proposition was agreed to at a general court held January the 9th, 1800. The conditions were, that the bank should advance to government 3,000,000l. for the service of the year 1800, on exchequer bills, payable, without interest, out of the supplies to be granted for the year 1806, in consideration of which the term of their charter was continued till the end of twelve months notice after the 1st of August 1833.

The amount of bank notes in circulation had gradually increased since the beginning of 1797; and, during the year 1800, amounted to about 15,000,000l. The amount, on an average of a month, to 25th of January 1801, was 16,365,200l.; consisting of 13,845,800l. in notes of 5l. and upwards, and 2,519,400l. in 1l. and 2l. notes.

At a general court, held 19th of March 1801, another occasional dividend of stock was proposed. This dividend was to be made of 582,120l. of 5 per cent. navy annuities, at the rate of 5 per cent. for every 100l. bank capital; and the transfer was made on the 1st of May.

The commerce of London itself is immense; not only as a seat of populous and luxurious consumption, but as a station of manufactures, and an emporium of maritime trade. The number of payments occasioned by such various transactions, is farther increased by the dividends which the national creditors receive on the great sum of our public debt. But in addition to all these payments, originating within the capital itself, bills are drawn upon London, and remittances are sent thither to provide for them, from all parts of the kingdom. Even foreign drafts, on account of merchants in the country, are, with scarcely any exceptions, made payable in London. And thus a great proportion of the pecuniary engagements, to which the whole commerce of the kingdom gives birth, are ultimately settled there. This transfer of the country payments to London, has, in some degree, subsisted for a long time; the practice, once begun, was likely, from its great advantage, to be gradually extended; and, of late years, it seems to have been reduced to a regular and very commodious system. It was much facilitated by the multiplication of country banks, during that period of high prosperity and confidence which immediately preceded the late war. The formation of these throughout the whole country was actively encouraged by the private bankers of London; and, indeed, the existence of a great national bank, which, like that of England, must provide a constant reservoir of gold, naturally suggests the creation of smaller establishments. Upon the formation of such banks in the country, many traders of all descriptions, who had formerly maintained a direct correspondence with merchants in London, fell into the practice of transacting their business with the metropolis through the banker in their own neighbourhood with whom they kept their cash. On their account, he drew largely upon a banker in London; who agreed to execute the extensive country business he had thus acquired, at a much lower commission than what had formerly been paid by the several country traders to their

their separate correspondents. The rate of commission was reduced, in consequence of the diminished trouble as well as risk; the labour of keeping accounts, writing letters, receiving and paying bills, was now transferred to one house, which had before been divided among many; and a new security was afforded to the transactions between the metropolis and the country, by the interposed credit of wealthy and respectable country banks.

The establishment of such a system of banks, and the transference of ultimate payments to one particular place, are in the natural course of that progressive subdivision of labour, which extends itself over an opulent and industrious country. The receipt and payment of money, instead of being conducted at home, are transferred, by every trader, to his banker; who derives means both of abridging his own labour, and of economising the use of money, especially of that costly part of it which consists of specie. By his skill and success in attaining these objects, he manages an important part of trade, at an expense far inferior to what the merchants themselves must have incurred, had they continued to conduct it separately by their own clerks. In proportion, likewise, as the amount and number of payments and receipts is augmented in one particular place, the business of paying and receiving is more easily and cheaply transacted; the guineas or bank notes required, though more upon the whole, are fewer in proportion to the sums paid and received. So complete, accordingly, and so systematic is that economy in the use of notes, which long experience has introduced among the London bankers, that the present payments of that metropolis could scarcely be transacted, with due regularity, if the quantity of notes were to suffer any considerable diminution. In this they are assisted by the fitness of bills of exchange and government securities to supply the place of bank notes; for the interest that grows on such negotiable paper while it is detained, saves all the loss which the banker would undergo from the detention of coin or notes; and there is a certain sort and quantity of bills, on the conversion of which into money he may rely almost as confidently as on the changing of a note into guineas, or of a guinea into silver. The ingenuity of these money-dealers, in springing the circulating medium, is aptly illustrated by a custom which prevails among the city bankers. Each of them sends a clerk, at an appointed hour in the afternoon, to a room provided for their use. Each clerk there exchanges the drafts on other bankers received at his own house for the drafts on his own house received at the houses of other bankers. The balances of the several bankers are transferred from one to another, in a manner which it is unnecessary to explain in detail, and the several balances are finally wound up by each clerk into one balance. The difference between the whole sum which each banker has to pay to all other city bankers, is, therefore, all that is discharged in bank notes or money; a difference evidently much less in its amount than that to which the several differences would be equal.

But the economised use of circulating medium is by no means the only collateral advantage that arises from this system of banks, connected in subordination to each other, with the great national bank at their head. Although a very few of the country establishments have occasionally subjected themselves to the charge of encouraging rash speculation, the system, in its complex operation, has a real tendency to strengthen as well as to enlarge the basis of credit. Bankers possess, from their situation, very superior means of distinguishing the careful trader from the improvident. The bill transactions of the neighbourhood pass under their inspection; and by this information they are

enabled to measure out confidence very nearly in a just proportion. In fact, it is considered as a regular branch of their professional experience, that they should appreciate the credit of the various traders within their district of circulation; and this sort of practical sagacity they are understood to cultivate with great assiduity. It is said to be the general practice of banks, to communicate such intelligence for their mutual advantage. Each of them endeavours to limit, not only the sum which any one trader shall obtain from themselves, but the total amount also, so far as they are able, of the sum which the same person shall borrow in different places. They endeavour, above all, to discourage bills of accommodation. While the transactions of country traders are thus surveyed by the banks of their respective districts, those of the country banks themselves are subject to the view of the London bankers, their correspondents; and these, again, are in some degree controlled by the bank of England, which restricts, according to its own discretion, the credit with which they are accommodated. A series of checks is thus maintained, which, though far from establishing a complete security against all injurious speculation, presents a powerful obstacle to its progress.

But the bank of England retains another check, of a highly important nature, over the banks in the country. The issue of its own notes is restricted, in ordinary times, by the obligation to convert them into specie. The quantity of country paper, even during the present times, is limited by its accustomed convertibility into the notes of the bank of England. If a particular country banker is imprudent enough to issue an extraordinary quantity of paper, while that of the bank of England does not exceed the demands of London circulation, a local rise of prices will be produced within the district of that country paper, but prices in London will remain as before. In this situation, the holders of country paper, in order that they may purchase goods where they are cheaper, will return that paper to the banker, demanding in return bank of England notes, or at least bills upon London. The excess of his notes will thus be continually returned upon the country banker, and he will at length find himself under the necessity of limiting his issue to that quantity which the circulation of his own district can absorb. The quantity of bank of England paper may thus be said to regulate the quantity of that which is issued by the country banks. It is not, that one uniform ratio is maintained between these two quantities; but that both are in the same proportion to the demand that is created for each by the trade which it is destined to circulate. Whenever the bank of England paper happens to exceed what is required for the purposes of London circulation, the country paper may become excessive in the same degree. And such an excess of bank of England paper may be produced, either by a diminution in the number of payments, while that of notes remains undiminished; or by whatever has a tendency, while the number of payments remains unaugmented, to augment the number or the effective power of the notes in circulation.

The most serious danger to which the bank of England is exposed is that of being drained of its specie. To such a drain it may be subjected in consequence of any alarm that occasions a great demand for guineas, either to be hoarded, or to supply the place of paper thrown out of circulation. If the alarm should be of long continuance, and the bank maintains in circulation no more than its usual quantity of notes, it may be altogether exhausted of its guineas, however small that quantity of notes may be; because if these are always re-issued in loans upon the discounts of bills, they may be perpetually returned upon the bank in demand for more specie.

Should

Should the alarm be great and of long continuance, the bank, by maintaining only a million of notes in circulation, may, by the continual return of these, be exhausted of fifty millions of guineas. Besides, a more permanent cause of a run upon the bank of England for specie is the excess of the market price of gold above its mint price. This was formerly occasioned by the debased state of gold currency; and the bank has been reduced to the necessity of coining new guineas, which were immediately melted down, that the bullion might be sold to the bank itself at the high market price. In whatever manner the high price of gold is produced, immediate demands are made upon the bank for guineas, in order to export them. These it endeavours to replace, though gold cannot be purchased without a considerable loss. A most unequal competition will thus be established between the bank, on the one hand, which buys and coins at a great loss, and the clandestine dealers, on the other hand, who melt and sell at a great profit. If the unfavourable balance of trade, which has caused this high price of bullion, were not of a temporary nature, the bank of England, by this continued accumulation of unproductive expence, might ultimately be reduced to very great distress. Besides, the excess of the market price of gold above its mint price may likewise be produced by too great a quantity of paper-money. The bank, indeed, has the power of restricting the country paper, by limiting its own notes to those which are actually needed for the purposes of circulation. It has, therefore, the power in a great degree of preventing that high price of gold, and the consequent drain of its own guineas, which proceed from an excessive circulation of paper. So long, then, as the bank is liable to payments in specie, it has an evident interest to prevent its own paper, as well as that of the whole country, from being so excessive, as to occasion a rise in the price of commodities. To limit the total amount of paper issued, and to resort, whenever the temptation of borrowing is strong, to some effectual principle of restriction; never to diminish greatly the sum in circulation, but to let it vibrate only within certain limits; to afford a slow and cautious extension of it, as the general trade of the country is enlarged; and to permit a temporary increase during an extraordinary period of difficulty or alarm:—this, according to Mr. Thornton (*ubi infra*), is the true policy of an institution placed in the circumstances of the bank of England.

If the bank of England, says an anonymous writer (*Edinb. Rev. N. I. p. 196.*), must now be considered as a national establishment, not merely influencing, by the superior magnitude of its capital, the state of commercial circulation, but guiding its movements according to views of public policy, an important revolution has taken place since the first erection of that corporation as a banking establishment. That power of issuing the medium of exchange, with the opportunities it implies of varying its quantity and value, which, while precious coin was in use, was exercised under the immediate prerogative of the crown, is now virtually invested in the governor and directors of the bank of England. In the official character of that board, some of the functions of sovereignty are united to those of a trader; and the opportunities of banking profits are blended with a trust and charge of the public interest. It will be pleasing if these shall prove more happily compatible, than they have been found in other instances. The organization of this establishment, possessed of such means to control the operations of commerce, as well as to facilitate the advance of financial supplies, may, into our political constitution already so complicated, introduce a new principle of action, the effect of which cannot be clearly discern-

ed. Perhaps an unbounded field will be opened for the extension of ministerial influence; perhaps an unexpected control may be gained to the people, over the views and measures of the executive.

The suspension of cash payments in 1797, was an event, in the opinion of Mr. Thornton, to which the national bank was liable from its very nature; the probability of which has been too studiously concealed; and to the recurrence of which we may look forward. The gold, in the coffers of the bank, had been much reduced by the effect of an unfavourable balance of trade. The alarms of invasion had led to the failure of some country banks in the north of England; this occasioned a further demand of guineas from the bank, and a diminution in the circulating notes of London. The directors aggravated the distress, and augmented the demand for guineas, by unwisely suppressing some of their notes, instead of enlarging the quantity. It has also been alleged, that the loans of the bank to government, which occasioned a limitation in its discount of commercial paper, contributed, by their indirect and unavoidable operation, to aggravate that distress of the circulation which was chiefly produced by other causes. Although the loans to government could have no tendency to diminish the sum of notes in circulation, it nevertheless tended to distress the circulation, by rendering that sum of notes less adequate to the wants of commerce, than if they had flowed into the market through the usual channel of discounts. The suspension of payments in specie was properly continued, according to Mr. Thornton, from the permanence of those circumstances which rendered it originally necessary:—an unfavourable exchange, produced partly by our heavy expenditures, but chiefly aggravated by vast importations of corn; and the prevalence, till the eve of peace, of alarms about hostile invasions. Mr. Thornton maintains that the circulating paper of the bank of England does not in fact amount now to a greater sum than, upon an average of years, was in circulation before the suspension of cash payments. Upon an average of three years, ending in December 1795, their amount, according to the evidence laid before parliament, was 11,975,573*l.* By a subsequent statement presented to the house of Commons, they amounted in December 1800, to 15,450,970*l.* From the difference between these two sums, Mr. Thornton insists that we ought to deduct the amount of two millions, consisting of one and two pound notes, which according to him have displaced in the circulation an equal sum of guineas. After this deduction, there still remains the sum of 1,475,397*l.* by which the bank paper exceeded in 1800, its average amount before the suspension of cash payments. But in the spring of 1801, the governor of the bank stated to the house of commons, that the company had reduced its notes to a sum less, by about a million and a half, than their amount in the preceding December. Lord King, in his "Thoughts on the Restriction of Payments in Specie at the Banks of England and Ireland," 8vo. 1803, disputes the correctness of Mr. Thornton's statement; and alleges, that in the spring of 1801, the issue of notes amounted to 16,365,206*l.* which was still farther increased, in the summer of 1802, to 16,747,300*l.* According to the last account presented to the house of commons, the bank of England notes in circulation amounted to 16,108,560*l.* If we compare, says his lordship, this sum with the above average of three years ending in December 1795, even after we add to the latter the whole two millions of which Mr. Thornton speaks, and which seems a very large allowance, the present issue from the bank will be found to exceed that, which was formerly convertible into specie, by something less than one-

sixth of the whole. If we consider the quick circulation which paper admits of, and the increase which an accelerated rate of circulation gives to the effective powers of currency, this addition of almost one-sixth must be regarded as an immense augmentation of the mass of efficient currency. While the issue of bank of England notes was moderate and restrained, the market price of bullion, particularly of silver bullion, which is a more certain standard than gold, because it is a more regular article of commerce, continued very nearly the same as its established price in our mint. In the summer of 1799, however, about the same time with the great increase of bank paper, a rapid and extraordinary advance took place in the market price of bullion. That of silver rose at once to 5s. 8d. almost ten per cent. above the mint price. It continued to rise along with the progressive increase of notes; and in 1801, when they exceeded sixteen millions, it was as high as 6s. more than 16 per cent. and even as 6s. 1d. more than 17 per cent. above the mint price. Thus also, while the issue of the bank of England notes was moderate and restrained, the rate of exchange at Hamburgh continued in favour of this country, being from three to five per cent. above par. But in the summer of 1799, about the same time with the great increase of bank paper, a very rapid fall took place. It fell at once to 32, above eight per cent. below par; and continued to fall almost regularly, though not quite so regularly as the price of bullion rose, along with the progressive increase of notes. At the commencement of 1801, when they exceeded sixteen millions, the exchange with Hamburgh was as low as 27l. 10s. almost 16 per cent. below par. Lord King has subjoined a set of tables, which exhibit the remarkable correspondence between the variations in the quantity of bank notes, and the variations in the price of bullion and rate of exchange. His lordship has also shewn, that the paper currency of the bank of Ireland has been augmented from 621,917l. to 2,633,854l.; and that its notes at present in circulation exceed more than four times the amount of what were in circulation when the act of restriction was passed. During the same period, the price of silver in Dublin has experienced a great advance, having varied from 6s. 6d. to 7s. Irish currency; an increase, which, estimating the mint price at 5s. 7d. is from 14 to 20 per cent. The rate of exchange between Dublin and London has been also remarkably affected; the difference having progressively increased from 8½, the ordinary difference, to 10, 12, 14, and even 16. This proof of the depreciation of bank of Ireland notes has not been confined to the course of exchange with London; but is felt in the transactions of Dublin with many of the provincial towns, where those notes have not acquired a general circulation; the currency still consisting either of specie, or of country notes. In consequence of this, and of the depreciated condition of the Dublin currency, there is an actual difference of exchange between Dublin and those towns. This is the case, for instance, in Belfast; when a payment is there made in bank of Ireland notes, an additional sum is paid proportional to the discount. Hence lord King infers, that the measure of 1797 has actually had a pernicious influence upon the system of circulation; and in strong terms deprecates its continuance. Mr. Thornton states the following fact, that the enumeration of *country-banks* taken in 1800, differed from that taken in 1797, by the excess of 386 above 353.

It is not, says Dr. Smith (*ubi infra*), by augmenting the capital of the country, but by rendering a greater part of that capital active and productive than would otherwise be so, that the most judicious operations of banking can increase the industry of the country. That

part of his capital which a dealer is obliged to keep by him unemployed, and in ready money for answering occasional demands, is so much dead stock, which, so long as it remains in this situation, produces nothing either to him or to his country. The judicious operations of banking enable him to convert this dead stock into active and productive stock; into materials to work upon, into tools to work with, and into provisions and materials to work for; into stock which produces something both to himself and to his country. The gold and silver money which circulates in any country, and by means of which the produce of its land and labour is annually circulated and distributed to the proper consumers, is, in the same manner, the ready money of the dealer, all dead stock. It is a very valuable part of the capital of the country, which produces nothing to the country. The judicious operations of banking, by substituting paper in the room of a great part of this gold and silver, enable the country to convert a great part of this dead stock into active and productive stock; into stock which produces something to the country. The gold and silver money which circulates in any country may very properly be compared to a highway, which while it circulates and carries to market all the grains and corn of the country, produces itself not a single pile of either. The judicious operations of banking, by providing, if I may be allowed the violent a metaphor, a sort of waggon-way through the air; enable the country to convert, as it were, a great part of its highways into good pastures and corn fields, and thereby to increase very considerably the annual produce of its land and labour. The commerce and industry of the country, however, it must be acknowledged, though they may be somewhat augmented, cannot be altogether so secure, when they are thus, as it were, suspended upon the Dedalian wings of paper money, as when they travel about upon the solid ground of gold and silver. Over and above the accidents to which they are exposed from the unskillfulness of the conductors of this paper money, they are liable to several others, from which no prudence or skill of those conductors can guard them. Mr. Hume (*Essays*, vol. i. *Ess. iii. p. 301.*) expresses his doubt concerning the benefit of banks and paper credit. That provisions and labour, he says, should become dear by the increase of trade and money, is, in many respects, an inconvenience, but an inconvenience that is unavoidable, and the effect of that public wealth and prosperity which are the end of all our wishes. It is compensated by the advantages, which we derive from the possession of these precious metals, and the weight which they give the nation in all foreign wars and negotiations. But there appears no reason, as he conceives, for increasing that inconvenience by a counterfeit money, which foreigners will not accept of for any payment, and which any great disorder in the state will reduce to nothing. (See *PAPER-MONEY*, *inquiry into the nature and effects of the Paper Credit of great Britain*, by Henry Thornton, Esq. M.P. London, 1802. *Smith's Nature and Causes of the Wealth of Nations*, vol. i. p. 479—484.

In Scotland, there are two *public* banks erected at Edinburgh; of which the one, called "The Bank of Scotland," was established by act of parliament in 1695; the other, called "The Royal Bank," by royal charter in 1727. New banking companies have been also erected within the last thirty and forty years in almost every considerable town, and even in some country villages. The business of the country, says Dr. Smith (*vol. i. p. 442*), is almost entirely carried on by means of the paper of these different banking companies, with which purchases and payments of all kinds are commonly made. Silver very seldom appears except in the

change of a twenty shilling bank note, and gold seldom. But though the conduct of all these different companies has not been unexceptionable, and has accordingly required an act of parliament to regulate it; the country, notwithstanding, has derived great benefit from their trade. It has been asserted, says this writer, that the trade of the city of Glasgow doubled in about fifteen years after the first erection of the banks there; and that the trade of Scotland has more than quadrupled since the first erection of the two public banks at Edinburgh. Whether this statement be strictly just or not, it is certain, that the trade and industry of Scotland have increased very considerably during this period, and it must be allowed, as an unquestionable fact, that the banks have greatly contributed to this increase. The whole value of the gold and silver, which circulated in Scotland before the union, cannot be estimated at less than a million sterling. In the present times, says Dr. Smith, the whole circulation of Scotland cannot be estimated at less than two millions, of which that part which consists in gold and silver, most probably, does not amount to half a million. But though the circulating gold and silver of Scotland have suffered so great a diminution during this period, its real riches and prosperity do not appear to have suffered any. In agriculture, manufactures, and trade, on the contrary, the annual produce of its land and labour has evidently been augmented. It is chiefly by discounting bills of exchange, that is, by advancing money upon them before they are due, that the greater number of banks and bankers issue their promissory notes; deducting always, upon the sum they advance, the legal interest till the bill shall become due. The payment of the bill when it becomes due, replaces to the bank the value of what had been advanced, together with a clear profit of the interest. The banker, who advances to the merchant whose bill he discounts, not gold and silver, but his own promissory notes, has the advantage of being able to discount to a greater amount by the whole value of his promissory notes, which he finds by experience are commonly in circulation. He is thereby enabled to make his clear gain of interest into a much larger sum. The commerce of Scotland was much less considerable than it is now, when the two first banking companies were established, and those companies would have had but little trade, if their business had been restricted to the discounting of bills of exchange. They invented, therefore, another method of issuing their promissory notes; by granting, what they called "cash accounts," that is, by giving credit to the extent of a certain sum (e. g. 2 or 3000 pounds), to any individual who could procure two persons of undoubted credit and good landed estate to become security for him, that whatever money should be advanced to him within the sum for which the credit had been given, should be repaid upon demand, together with the legal interest. Credits of a similar kind are commonly granted by banks and bankers, in all different parts of the world. But the easy terms upon which the Scotch banking companies accept of repayment are, says Dr. Smith, peculiar to them, and have, perhaps, been the principal cause, both of the great trade of these companies, and of the benefits which the country has received from it. Whoever has a credit of this kind with one of these companies, and borrows e. g. a thousand pounds upon it, may repay this sum by piece-meal, by 20l. and 30l. at a time; the company discounting a proportionable part of the interest of the great sum from the day on which each of those small sums is paid in, till the whole be in this manner repaid. All merchants, therefore, and almost all men of business, find it convenient to keep such cash accounts with them, and are thereby interested to promote the trade of those

companies, by readily receiving their notes in all payments, and by encouraging all those with whom they have any influence to do the same. The banks, when their customers apply to them for money, generally advance it to them in their own promissory notes. These the merchants pay away to the manufacturers for goods, the manufacturers to the farmers for materials and provisions, the farmers to their landlords for rent, the landlords repay them to the merchants for the conveniences and luxuries with which they supply them, and the merchants again return them to the banks in order to balance their cash accounts, or to replace what they may have borrowed of them; and thus almost the whole money business of the country is transacted by means of them. Hence the great trade of those companies.

By means of these cash accounts, every merchant can, without imprudence, carry on a greater trade than he otherwise could do. If there are two merchants, one in London, and the other in Edinburgh, who employ equal stocks in the same branch of trade, the Edinburgh merchant can, without imprudence, carry on a greater trade, and give employment to a greater number of people, than the London merchant. The London merchant must always keep by him a considerable sum of money, either in his own coffers, or those of his banker, who gives him no interest for it, in order to answer the demands continually coming upon him for payment of the goods which he purchases upon credit. Let the ordinary amount of this sum be supposed 500l. The value of the goods in his warehouse must always be less by 500l. than it would have been, had he not been obliged to keep such a sum unemployed. Let us suppose that he generally disposes of his whole stock upon hand, or of goods to the value of his whole stock upon hand, once in the year. By being obliged to keep so great a sum unemployed, he must sell in a year 500l. worth less goods than he might otherwise have done. His annual profits must be less by all that he could have made by the sale of 500l. worth more goods; and the number of people employed in preparing his goods for market, must be less by all those that 500l. more stock could have employed. The merchant in Edinburgh, on the other hand, keeps no money unemployed for answering such occasional demands. When they actually come upon him, he satisfies them from his cash account with the bank, and gradually replaces the sum borrowed with the money or paper which comes in from the occasional sales of his goods. With the same stock, therefore, he can without imprudence, have at all times in his warehouse a larger quantity of goods than the London merchant; and can thereby both make a greater profit himself, and give constant employment to a greater number of industrious people who prepare those goods for the market. Hence the great benefit which the country has derived from this trade.

The late multiplication of banking companies in both parts of the united kingdom, an event by which many people have been much alarmed, instead of diminishing, increases the security of the public. It obliges all of them to be more circumspect in their conduct, and, by not extending their currency beyond its due proportion to their cash, to guard themselves against those malicious runs, which the rivalry of so many competitors is always ready to bring upon them. It restrains the circulation of each particular company within a narrower circle, and reduces their circulating notes to a smaller number. By dividing the whole circulation into a greater number of parts, the failure of any company, an accident which, in the course of things, must sometimes happen, becomes of less consequence to the public. This free competition too obliges all bankers to be

more liberal in their dealings with their customers, and their rivals should carry them away. In general, if any branch of trade, or any division of labour, be advantageous to the public, the freer and more general the competition, it will always be the more so. Smith's *Wealth of Nations*, vol. i. p. 446, &c. p. 498, &c.

BANKS of Deposit are such as are instituted wholly for the benefit of the public. Of these Dr. Smith has given the following account: "The currency of a great state, such as France or England, generally consists almost entirely of its own coin. Should this currency, therefore, be at any time worn, clipped, or otherwise degraded below its standard value, the state by a reformation of its coin can effectually re-establish its currency. But the currency of a small state, such as Genoa or Hamburgh, can seldom consist altogether in its own coin, but must be made up, in a great measure, of the coins of all the neighbouring states with which its inhabitants have a continual intercourse. Such a state, therefore, by reforming its coin, will not always be able to reform its currency. If foreign bills of exchange are paid in this currency, the uncertain value of any sum, of what is in its own nature so uncertain, must render the exchange always very much against such a state, its currency being, in all foreign states, necessarily valued even below what it is worth.

In order to remedy the inconvenience to which this disadvantageous exchange must have subjected their merchants, such small states, when they began to attend to the interest of trade, have frequently enacted, that foreign bills of exchange of a certain value should be paid, not in common currency, but by an order upon, or by a transfer in the books of a certain bank, established upon the credit, and under the protection of the state; this bank being always obliged to pay, in good and true money, exactly according to the standard of the state. The bank of Venice established in 1157, that of Genoa in 1345, that of Amsterdam in 1609, that of Hamburgh in 1619, and the bank of Nuremberg, seem to have been all originally established with this view, though some of them may have afterwards been made subservient to other purposes. The money of such banks being better than the common currency of the country, necessarily bore an agio, which was greater or smaller, according as the currency was supposed to be more or less degraded below the standard of the state. The agio of the bank of Hamburgh, for example, which is said to be commonly about fourteen per cent. is the supposed difference between the good standard money of the state, and the clipped, worn, and diminished currency, poured into it from all the neighbouring states.

Before 1609, the great quantity of clipped and worn foreign coin which the extensive trade of Amsterdam brought from all parts of Europe, reduced the value of its currency about nine per cent. below that of good money fresh from the mint. Such money no sooner appeared than it was melted down or carried away, as it always is in such circumstances. The merchants, with plenty of currency, could not always find a sufficient quantity of good money to pay their bills of exchange; and the value of those bills, in spite of several regulations which were made to prevent it, became in a great measure uncertain.

In order to remedy these inconveniences, a bank was established in 1609, under the guarantee of the city. This bank received both foreign coin, and the light and worn coin of the country, at its real intrinsic value in the good standard money of the country, deducting only so much as was necessary for defraying the expence of coinage, and the other necessary expence of management. For the value

which remained after this small deduction was made, it gave a credit in its books. This credit was called *bank money*, which, as it represented money exactly according to the standard of the mint, was always of the same real value, and intrinsically worth more than current money. It was at the same time enacted, that all bills drawn upon or negotiated at Amsterdam, of the value of six hundred guilders and upward, should be paid in bank money, which at once took away all uncertainty in the value of those bills. Every merchant, in consequence of this regulation, was obliged to keep an account with the bank in order to pay his foreign bills of exchange, which necessarily occasioned a certain demand for bank money.

Bank money, over and above both its intrinsic superiority to currency, and the additional value which it obtained necessarily gives it, has likewise some other advantages. It is secure from fire, robbery, and other accidents; the city of Amsterdam is bound for it; it can be paid away by a simple transfer, without the trouble of counting, or the risk of transporting it from one place to another. In consequence of these different advantages, it seems from the beginning to have borne an agio, and it is generally believed, that all the money originally deposited in the bank was allowed to remain there, nobody caring to demand payment of a debt which he could sell for a premium in the market. By demanding payment of the bank, the owner of a bank credit would lose this premium. As a shilling fresh from the mint will buy no more goods in the market than one of our common worn shillings, so the good and true money which might be brought from the coffers of the bank into the hands of a private person, being mixed and confounded with the common currency of the country, would be of no more value than that currency, from which it could no longer be readily distinguished. While it remained in the coffers of the bank, its superiority was known and ascertained. When it had come into those of a private person, its superiority could not well be ascertained without more trouble than perhaps the difference was worth. By being brought from the coffers of the bank, besides, it lost all the other advantages of bank money; its security, its easy and safe transferability, its use in paying foreign bills of exchange. Over and above all this, it could not be brought from those coffers, as will appear by and by, without previously paying for the keeping.

Those deposits of coin, or those deposits which the bank was bound to restore in coin, constituted the original capital of the bank, or the whole value of what was represented by what is called bank money. At present they are supposed to constitute but a very small part of it. In order to facilitate the trade in bullion, the bank has been for these many years in the practice of giving credit in its books upon deposits of gold and silver bullion. This credit is generally about five per cent. below the mint price of such bullion. The bank grants at the same time what is called a receipt or receipt, entitling the person who makes the deposit, or the bearer, to take out the bullion again at any time within six months, upon transferring to the bank a quantity of bank money equal to that for which credit had been given in its books when the deposit was made, and upon paying one-fourth per cent. for the keeping, if the deposit was in silver; and one-half per cent. if it was in gold; but at the same time declaring, that in default of such payment, and upon the expiration of this term, the deposit should belong to the bank at the price at which it had been received, or for which credit had been given in the transfer books. What is thus paid for the keeping of the deposit may be considered as a sort of warehouse rent; and why this is a re-

house rent should be so much dearer for gold than for silver, several different reasons have been assigned. The fineness of gold, it has been said, is more difficult to be ascertained than that of silver. Frauds are more easily practised, and occasion a greater loss in the most precious metal. Silver, besides, being the standard metal, the state, it has been said, wishes to encourage more the making of deposits of silver than those of gold.

Deposits of bullion are most commonly made when the price is somewhat lower than ordinary; and they are taken out again when it happens to rise. In Holland, the market price of bullion is generally above the mint price, for the same reason that it was so in England before the late reformation of the gold coin. The difference is said to be commonly from about six to sixteen stivers upon the mark, or eight ounces of silver of eleven parts fine, and one part alloy. The bank price, or the credit which the bank gives for the deposits of such silver (when made in foreign coin, of which the fineness is well known and ascertained, such as Mexico dollars), is twenty-two guilders the mark; the mint-price is about twenty-three guilders, and the market-price is from twenty-three guilders six, to twenty-three guilders sixteen stivers, or from two to three per cent. above the mint price. The proportions between the bank price, the mint price, and the market price, of gold bullion, are nearly the same. A person can generally sell his receipt for the difference between the mint price of bullion and the market price. A receipt for bullion is almost always worth something, and it very seldom happens, therefore, that any body suffers his receipt to expire, or allows his bullion to fall to the bank at the price at which it had been received, either by not taking it out before the end of the six months, or by neglecting to pay the one-fourth or one-half per cent. in order to obtain a new receipt for another six months. This, however, though it happens seldom, is said to happen sometimes, and more frequently with regard to silver, on account of the higher warehouse rent which is paid for keeping of the more precious metal.

The person who by making a deposit of bullion obtains both a bank credit and a receipt, pays his bills of exchange as they become due with his bank credit; and either sells or keeps his receipt according as he judges that the price of bullion is likely to rise or to fall. The receipt and the bank credit seldom keep long together, and there is no occasion that they should. The person who has a receipt, and who wants to take out bullion, finds always plenty of bank credits, or bank money to buy at the ordinary price; and the person who has bank money, and wants to take out bullion, finds receipts always in equal abundance.

The owners of bank credits, and the holders of receipts, constitute two different sorts of creditors against the bank. The holder of a receipt cannot draw out the bullion for which it is granted, without re-assigning to the bank a sum of bank money equal to the price at which the bullion had been received. If he has no bank money of his own, he must purchase it of those who have it. The owner of bank money cannot draw out bullion without producing to the bank receipts for the quantity which he wants. If he has none of his own, he must buy them of those who have them. The holder of a receipt, when he purchases bank money, purchases the power of taking out a quantity of bullion, of which the mint price is five per cent. above the bank price. The agio of five per cent. therefore, which he commonly pays for it, is paid, not for an imaginary, but for a real value. The owner of bank money, when he purchases a receipt, purchases the power of taking out a quantity of bullion of which the market price is commonly from

two to three per cent. above the mint price. The price of the receipt, and the price of the bank money, compound or make up between them the full value or price of the bullion.

Upon deposits of the coin current in the country, the bank grants receipts likewise as well as bank credits; but those receipts are frequently of no value, and will bring no price in the market. Upon ducatoons, for example, which in the currency pass for three guilders three stivers each, the bank gives a credit of three guilders only, or five per cent. below their current value. It grants a receipt likewise entitling the bearer to take out the number of ducatoons deposited at any time within six months, upon paying one-fourth per cent. for the keeping. This receipt will frequently bring no price in the market. Three guilders bank money generally sell in the market for three guilders three stivers, the full value of the ducatoons, if they were taken out of the bank; and before they can be taken out, one-fourth per cent. must be paid for the keeping, which would be mere loss to the holder of the receipt. If the agio of the bank, however, should at any time fall to three per cent. such receipts might bring some price in the market, and might sell for one and three-fourths per cent. But the agio of the bank being now generally about five per cent. such receipts are frequently allowed to expire, or, as they express it, to fall to the bank. The receipts which are given for deposits of gold ducats fall to it yet more frequently, because a higher warehouse rent, or one half per cent. must be paid for the keeping of them before they can be taken out again. The five per cent. which the bank gains, when deposits either of coin or bullion are allowed to fall to it, may be considered as the warehouse rent for the perpetual keeping of such deposits.

The sum of bank money for which the receipts are expired must be very considerable. It must comprehend the whole original capital of the bank, which, it is generally supposed, has been allowed to remain there from the time it was first deposited, nobody caring either to renew his receipt or to take out his deposit, as for the reasons already assigned, neither the one nor the other could be done without loss. But whatever may be the amount of this sum, the proportion which it bears to the whole mass of bank money is supposed to be very small. The bank of Amsterdam has for these many years past been the great warehouse of Europe for bullion, for which the receipts are very seldom allowed to expire, or, as they express it, to fall to the bank. The far greater part of the bank money, or of the credits upon the books of the bank, is supposed to have been created, for these many years past, by such deposits which the dealers in bullion are continually both making and withdrawing.

No demand can be made upon the bank but by means of a receipt or receipt. The smaller mass of bank money, for which the receipts are expired, is mixed and confounded with the much greater mass for which they are still in force; so that, though there may be a considerable sum of bank money, for which there are no receipts, there is no specific sum or portion of it which may not at any time be demanded by one. The bank cannot be debtor to two persons for the same thing; and the owner of bank money who has no receipt, cannot demand payment of the bank till he buys one. In ordinary and quiet times, he can find no difficulty in getting one to buy at the market price, which generally corresponds with the price at which he can sell the coin or bullion it entitles him to take out of the bank.

It might be otherwise during a public calamity; an invasion

invasion for example, such as that of the French in 1672. The owners of bank money being then all eager to draw it out of the bank, in order to have it in their own keeping, the demand for receipts might raise their price to an exorbitant height. The holders of them might form extravagant expectations, and instead of two or three per cent. demand half the bank money for which credit had been given upon the deposits that the receipts had been respectively granted for. The enemy, informed of the constitution of the bank, might even buy them up, in order to prevent the carrying away of the treasure. In such emergencies, the bank, it is supposed, would break through its ordinary rule of making payment only to the holders of receipts. The holders of receipts, who had no bank money, must have received within two or three per cent. of the value of the deposit for which their respective receipts had been granted. The bank, therefore, it is said, would in this case make no scruple of paying, either with money or bullion, the full value of what the owners of bank money who could get no receipts were credited for in its books: paying at the same time two or three per cent. to such holders of receipts as had no bank money, that being the whole value which in this state of things could justly be supposed due to them.

Even in ordinary and quiet times it is the interest of the holders of receipts to depress the agio, in order either to buy bank money (and consequently the bullion, which their receipts would then enable them to take out of the bank) so much cheaper, or to sell their receipts to those who have bank money, and who want to take out bullion, so much dearer; the price of a receipt being generally equal to the difference between the market price of bank money and that of the coin or bullion for which the receipt had been granted. It is the interest of the owners of bank money, on the contrary, to raise the agio, in order either to sell their bank money so much dearer, or to buy a receipt so much cheaper. To prevent the stock jobbing tricks which these opposite interests might sometimes occasion, the bank has of late years come to the resolution to sell at all times bank money for currency, at five per cent. agio, and to buy it again at four per cent. agio. In consequence of this resolution, the agio can never either rise above five, or sink below four per cent. and the proportion between the market price of bank and that of current money, is kept at all times very near to the proportion between their intrinsic values. Before this resolution was taken, the market price of bank money used sometimes to rise so high as nine per cent. agio, and sometimes to sink so low as par, according as opposite interests happened to influence the market.

The bank of Amsterdam professes to lend out no part of what is deposited with it, but, for every guilder for which it gives credit in its books, to keep in its repositories the value of a guilder either in money or bullion. That it keeps in its repositories all the money or bullion for which there are receipts in force, for which it is at all times liable to be called upon, and which, in reality, is continually going from it and returning to it again, cannot well be doubted. But whether it does so likewise with regard to that part of its capital, for which the receipts are long ago expired, for which in ordinary and quiet times it cannot be called upon, and which in reality is very likely to remain with it for ever, or as long as the states of the United Provinces subsist, may perhaps appear more uncertain. At Amsterdam, however, no point of faith is better established than that for every guilder, circulated as bank money, there is a correspondent guilder in gold or silver to be found in the treasure of the bank. The city is guarantee that it should be so. The

bank is under the direction of four reigning burgoesters, who are chosen every year. Each head of a household annually visits the treasury, compares it with his books, receives it upon oath, and delivers it over, with the most awful solemnity to the fit which succeed; and that in a liberal and religious country, oaths are not yet to be despised. A rotation of this kind seems above a self-denial necessary against any practice which cannot be avowed. Should all the revolutions which faction has ever occasioned in the government of Amsterdam, the prevailing party has at no time accused their predecessors of infidelity in the administration of the bank. No accusation could have affected more deeply the reputation and fortune of the disgraced party, and if such an accusation could have been supported, we may be assured, that it would have been brought. In 1672, when the French king was at Utrecht, the bank of Amsterdam paid so readily as left no doubt of the fidelity with which it had observed its engagements. Some of the pieces which were then brought from its repositories appeared to have been scorched with the fire which happened in the town-house soon after the bank was established. Those pieces, therefore, must have lain there from that time.

What may be the amount of the treasure in the bank, is a question which has long employed the speculations of the curious. Nothing but conjecture can be offered concerning it. It is generally reckoned that there are about two thousand people who keep accounts with the bank, and allowing them to have, one with another, the value of fifteen hundred pounds sterling lying upon their respective accounts (a very large allowance), the whole quantity of bank money, and consequently of treasure in the bank, will amount to about three millions sterling, or at eleven guilders, the pound sterling, thirty-three millions of guilders; a great sum, and sufficient to carry on a very extensive circulation, but vastly below the extravagant ideas which some people have formed of this treasure.

The city of Amsterdam derives a considerable revenue from the bank. Besides what may be called the warehouse rent above-mentioned, each person, upon first opening an account with the bank, pays a fee of ten guilders; and for every new account, three guilders three stivers; for every transfer two stivers; and if the transfer is for less than three hundred guilders, six stivers, in order to discourage the multiplicity of small transactions. The person who neglects to balance his account twice in the year forfeits twenty-five guilders. The person who orders a transfer for more than is upon his account, is obliged to pay three per cent. for the sum overdrawn, and his order is set aside into the bargain. The bank is supposed too to make a considerable profit by the sale of the foreign coin or bullion which sometimes falls to it by the expiring of receipts, and which is always kept till it can be sold with advantage. It makes a profit likewise by selling bank money at five per cent. agio, and buying it in at four. These different emoluments amount to a good deal more than what is necessary for paying the salaries of officers, and defraying the expence of management. What is paid for the keeping of bullion upon receipts, is alone supposed to amount to a neat annual revenue of between one hundred and fifty thousand and two hundred thousand guilders. Public utility, however, and not revenue, was the original object of this institution. Its object was to relieve the merchants from the inconvenience of a disadvantageous exchange. The revenue which has arisen from it was unforeseen, and may be considered as accidental. Smith's Wealth of Nations, vol. ii. p. 219

BANK of France was first projected by Mr. Law, a native of Scotland, with a view of paying off the public debts of France, by drawing its creditors into the newly projected Mississippi and India companies, and erected in the year 1716. It was taken into the king's hands in 1718, and denominated the royal bank; and by its union with both the companies above-mentioned, formed a bubble, which occasioned great confusion and distress in the year 1720.

BANK, Million, derived its name from king William's million lottery in the year 1693; the proprietors agreeing in partnership to purchase tickets in this lottery. They afterwards purchased many reversions of the 4 per cent. annuities, and admitted many proprietors of annuities to purchase their joint stock, which amounted to 520,000*l*. They were a partnership by deed enrolled in chancery, in the year 1721. They divided 5 per cent. till Lady-day 1728, when they reduced their annual dividend to 4 per cent. and it was again raised to 5 per cent. which it continued till its dissolution.

BANK of Loan, Copenhagen, has a capital stock, consisting of 500,000 rix-dollars, each being of the value of about 4*s*. 6*d*. sterling. Its notes are received in payment of the royal revenues. It lends money on pledges, not exceeding 100 rix-dollars, at an interest of 4 per cent. In 1762, his Danish majesty directed the bank for current cash-notes, to exchange their 100 rix-dollar notes, for notes of 50, 10, or 1 rix-dollar: and not to pay to any one person above one crown in specie.

BANK of Rotterdam was erected in 1635. It pays bills of exchange in large money, and only 10 per cent. in shillings.

BANK of Assiguation, a new bank established in Russia during the hostilities against the Turks. When copper-money could not be coined with sufficient expedition to answer the necessities of the state, bank-notes to the value of 50, 75, and 100 rubles, in copper, were issued. These notes are changed at the bank in Peterburgh and Moscow. The former is a brick building, containing several vaulted rooms, each capable of holding 400,000*l*. of copper coin in bags, piled one above another. Since the year 1784, the old bank notes were called in, and a new issue made to the acknowledged amount of 100,000,000 rubles, in notes of 5, 10, 15, 25, and 100 rubles. On the first appearance of this paper, it was received, particularly in the remote parts of the empire, not without difficulty, and the discount against it was commonly about 3*½*%, and in some places even 6 per cent. The obvious advantages, however, over copper money soon recommended it to general use, and it was found so beneficial to commerce, that in 1779 the discount in favour of silver specie was only 1 per cent. and it bore a premium of 1*½* per cent. over copper money. But so large a quantity was circulated, and the loans to government so lowered the credit of the state, that in 1790 the discount against the paper currency was near 20 per cent.

The *Loan Bank* is an institution established at Peterburgh for the benefit of the nobility and corporations. With this view Catherine II. in 1786, made a deposit of 22 millions of rubles for the nobility, 11 millions for the corporate towns, and 3 millions for the province of Taurida, to be lent out for the improvement of rural economy, of social industry, and the benefit of civilization in general. This bank lends only on real estates. As the value of a landed estate in Russia is estimated according to the number of boors upon it, the bank takes the boors at 40 rubles per head; so that the proprietor of an estate, requiring the loan of 1000 rubles, must give 25 boors as his pledge. The loan is made for 20 years; the mortgagor annually paying 5 per cent. interest,

and 3 per cent. on the capital, so that after 20 years he has paid back the whole of his loan. The loans are subject to no other limitations than what arise from the value and the security of the pledge; every one being allowed to apply for and receive as much money as he is capable of laying down a lawful pledge for. The bank, however, lends no sum under 1000 rubles, and only by thousands, for the sake of avoiding perplexing accounts. The mortgaged property is subject to no suit, to no confiscation, nor to any demands from the crown or from private individuals. Every four years one part of the pawn is discharged, equal in value to that part of the capital already paid. The bank can redeem estates elsewhere mortgaged or appropriated to the payment of debts; and mortgaged estates may be sold; but in that case the purchaser takes upon himself all the obligations which the seller was under to the bank. The municipal magistracy vouches for the worth of the pledge; and must be responsible for it. The interest is paid annually. The bank gives ten days grace; whoever exceeds one month pays a stated penalty per cent. and this likewise holds good beyond three months, the mortgaged estate is taken into charge by the noble court of wards. The interest and fines are paid from the incomings of the estate, and the remainder is paid to the proprietor. The inhabitants of towns obtain loans on their real estates, paying yearly 4 per cent. interest, and 3 per cent. capital, and are consequently freed from their debt in 22 years. Storck's *Pict.* of Peterfb. p. 211.

BANK of Philadelphia, called the *Bank of the United States*, was founded in 1787, and seems to have been successful. Its capital stock was 10 millions of dollars.

BANK of Stockholm owes its origin to Palmshut, a merchant, who carried on an extensive trade, and possessed great property in iron mines. He established at Stockholm a bank for the purpose of exchanging and lending money, divided into two departments. Such was his credit, and such were his resources, that, though he was the only banker in the kingdom, and his connections of course very extensive, the notes which he issued at the interest of 8 per cent. for a term of ten years and upwards, were circulated through the kingdom, and received as cash by the trading part of the nation. In process of time, by the issue of counterfeit notes and other unfavourable circumstances, the bank was drained of cash, and its credit was in danger of sinking into disrepute. In this dilemma Palmshut applied to Charles XI., and induced the king to take the bank under his royal direction. Accordingly, the king appointed Palmshut director, and having established the credit of the bank, transferred the direction of it to the states of the kingdom assembled in 1688; and declared himself and his successors protectors of the bank, but renounced all interference in the disposal of the money. The states being thus declared guarantors, proprietors, and directors of the bank, several regulations were made. The bank was permitted to lend money on good security, at the interest of 8 per cent. but to pay for all money borrowed only 6 per cent.; the debtors to discharge interest upon interest, but the bank not to pay interest upon interest; all the king's revenues were to be deposited in the bank, without receiving interest. The bank was empowered to issue notes not exceeding the value of thirty-six dollars copper mint, or ten shillings; and it was finally resolved, that the states, or those whom they should depute, should have the power of inspecting the accounts, and inquiring into the nature of its constitution. By these regulations the credit and riches of the bank increased to such a degree, that towards the close of the 17th century, it became the universal depositary of the whole kingdom,

both

both as to public and private circulation, and lowered the interest from 8 to 7, and afterwards to 6, 4, and 3 per cent. In return, the interest for all money borrowed, or deposited in the bank by way of loan, was likewise lessened from 6 to $4\frac{1}{2}$, 3 and 2 per cent. The large quantity of copper money then current in the country, being by its bulk and weight extremely inconvenient, the circulation of bank notes became advantageous to commerce. From 1714 to 1717, the bank supplied Charles XII. with such considerable sums, that the revenues arising from the tolls and customs were insufficient to pay the interest, and of course there was a considerable deficiency. These supplies lowered the credit of the bank in the estimation of the public; and therefore the king, on the remonstrance of the states, mortgaged certain revenues of the crown, for the discharge of the interest; and declared that all the revenues then mortgaged should remain in the bank till the debt should be fully discharged, and also promised, that he would not, on any pretext or emergency, recur again to the bank for money, except for such as belonged to the crown. Its credit was thus in some measure retrieved; but its stock was too far drained to repair its former credit, until baron Goertz undesignedly contributed to it by a scheme which was in every other respect detrimental to the nation. To supply Charles with money for his constant wars, Goertz compelled persons, by means of fines and penalties, and afterwards by a species of torture, to deliver up their plate, jewels, and coin. In return for these effects, they received copper-money, called "Myntellen," or signs of coins, each weighing only one-third of a silver, but passing for a silver dollar, or which it was only a ninety-sixth part. The public secretly transferred their property, consisting of plate, jewels, and money, which was thus to be forced from them and exchanged for a debased currency, to the bank, confiding in the royal promise, that the bank should be exempted from the interference and inspection of the crown. Goertz advised the king to seize the property deposited in the bank; but Charles refused to violate his promise, and prohibited Goertz from making any proposals tending to the prejudice of the bank. In this crisis, the bank received such large sums of money, a great part of which paid no interest, that the profits were very considerable. Accordingly the bank, in this flourishing state, was induced, by order of the states, in 1741, to present the king with a donation of 100,000 silver dollars, or 8,333l. 4s., and to furnish him with 500,000, or 41,666l., without interest, towards carrying on the war against Russia. Since that period it has frequently advanced large sums of money to the crown and to the board of manufactures, by order of the states. The bank is divided into two departments; *lone*, or loan; and *wechel*, or exchange bank; each keeping separate accounts, but mutually supplying the other as occasion requires. The former lends money on mortgages or pledges. The proprietors on depositing these pledges in the bank, receive the full value, on paying 3 per cent. annual interest; these pledges consist of gold and silver in block, copper, brass, and half-bank felder, or certificates of having sent money to the bank; and particularly iron, for which latter article the proprietor receives three-fourths of its value at the interest of 3 per cent.; and when he disposes of it, it is again delivered to him on producing a certificate from the bank that the loan is duly discharged. Jewels were formerly received as pledges; but as their value is fluctuating, and the bank was once defrauded in that article, they are no longer admitted. Mortgaged lands and houses, being of a less certain value than other articles, pay an interest of 4 per cent. on the

money borrowed; and for the purpose of liquidating the debt, the following regulations were adopted: all borrowers on lands and houses shall pay 6 per cent. yearly; of this sum 4 per cent. is the lawful interest, and the remaining 2 per cent. is annually deducted from the capital, by which means the original debt is gradually diminished.

The *wechel*, or exchange bank, exchanges and issues bank notes, discounts bills, receives and assigns the money deposited for interest or security, and discounts the interest of 2 per cent. on all money placed in their hands. Towards the latter end of the reign of Adolphus Fredric, bank notes were issued in such numbers, and many of them at so low a value as 1s. 6d., that scarcely any specie was left in the kingdom; the bank was so drained of cash as not to be able to exchange its notes except in copper-money, and paper was almost the only currency. For preventing a total bankruptcy, and calling in the paper currency, the states, in 1766, voted a loan of 3,000,000 rix-dollars, or 750,000l. to effect the realization of the bank notes, and to circulate a sufficient quantity of specie. Other regulations were also adopted; and in order to counteract the effects of party, the diet, in 1772, committed to the king the difficult province of realizing the bank notes, and reforming the currency, which was happily effected. In 1777 and 1779, the states confirmed the realization, and made several new regulations, for securing the credit of the bank, and rendering it still farther independent of the crown. The independence of the bank was farther established by the diet of 1784. The accounts were submitted to a committee of revisors, which consists of a certain number of persons chosen by the three houses of nobles, clergy, and burghers, from their respective orders, who continue in office till the meeting of a new diet, when they are either renewed or confirmed. They assemble once every three years, and continue sitting not more than a month. They inspect the general state of the bank, compare the accounts of the directors, and observe that no abuses have been committed, and that the regulations of the states have been observed. Cox's Travels in Sweden, &c. vol. iv. p. 130—139.

BANK, *Agents of*. See AGENT.

BANK-Bills. See BILL.

BANK, *Days in*. See DAY.

BANK, *Land*, an institution projected during the years 1694 and 1695, by Dr. Hugh Chamberlain, for lending of money at a low interest on land security, which was the principal difference between this and the bank of England; in opposition to which corporation, then in its infancy and struggling with difficulties, this ill-judged project was set up. It was principally encouraged by the Tory party; and an act of parliament, viz. 7 & 8 W. III. c. 21, was obtained for the purpose. The subscriptions for its establishment failed, and the plan proved abortive.

BANK Notes. See NOTE.

BANK, or *Bank*, in *Law*. See BANK.

BANK, *Foot*. See BANQUET.

BANK, in *Natural History*, denotes an elevation of the ground, or bottom of the sea, so as sometimes to surmount the surface of the water, or at least to leave the water so shallow, as usually not to allow a vessel to remain afloat over it. In this sense, bank amounts to much the same with flat, shoal, &c.

There are banks of sand, and others of stone, called also shelves or rocks. In the North sea, they also speak of banks of ice, which are large pieces of that matter floating. See ICEBERGS.

Vapours at sea sometimes occasion such a *delirio visio*, that mariners imagine they see land with trees, &c. They

call such deceptions fog-banks. For the account of a remarkable deception of this kind, see Dr. Hawklworth's Account of the Voyages to the Southern Hemisphere, vol. i. p. 10. A long narrow bank is sometimes called a *rib*.

The *bank* absolutely so called, or the *main bank*, or *great bank*, denotes that of Newfoundland, the scene of the cod-fishery.

It is called the *great bank*, not only by reason of its vast extent, being, according to the English computation, two hundred miles long, and, according to the French, one hundred leagues, or three hundred miles; but also on account of several lesser banks near it, where cod are also caught. These last the French call *banquesaux*.

This is one of those banks which have water enough to float a ship, and which, on this account, are not dangerous.

Banks are usually distinguished by a buoy, post, or the like. On charts, sand-banks are usually marked by little dots, and banks of stone by crosses. The colours of the buoys are also varied accordingly; sand-banks being denoted by light-coloured buoys, and rocks by black ones.

In large rivers, as the Elbe, &c. sandbanks, by high tides and inundations, are liable to change places; care is therefore taken to shift the buoys from time to time, to shew the true channel of the river.

An exact knowledge of the banks, their extent, and the depth of water on them, makes the most essential part of the science of a pilot, and a master of a ship: if the vessel be large, and draw much water, great attention will be necessary to keep clear of the banks: on the contrary, if it be small, the same banks afford a sure asylum, where it may brave the largest and stoutest vessels, which dare not follow it here. By means of this barrier, many a small craft has escaped its enemy.

BANK, in vessels which move with oars, is used for the bench where the rowers are seated; popularly called, by our seamen, the *thought*.

In this sense we read of banks of galleys, of galleasses, of galliots, of brigantines, and the like.

The Venetian gondolas have no banks; for the watermen row standing.

The common galleys have twenty-five banks, that is, twenty-five on each side, in all fifty banks, with one oar to each bank, and four or five men to each oar. The galleasses have thirty-two banks on a side, and six or seven rowers to a bank. See **DOUBLE-BANKED**.

BANK also denotes an elevation of earth, stones, flukes, or other materials in form of a wall, or causeway, to stop the waters, and prevent inundations.

These, on other occasions, are denominated *dams*, and *sea-walls*, &c. and by the ancients *aggeres*; those on the coasts of Holland are more particularly denominated *dykes*. The best bank, in the opinion of Dr. Hales, is that contrived by Dr. Wark of Scotland. A quantity of furze is fixed to the bottom of the channel, of such a breadth as is proportioned to the force which it is to resist. The sand, or slime, will soon settle in the furze, and when this is covered, another bed of furze is to be laid on as before, and so on till the bank is raised to a sufficient height.

BANK is also used in several games, for the stock or fund of him who undertakes the game.

BANK at buffet, a sum of money laid down by the *tailleur*, before the gamblers, to answer all the winning cards that shall turn up in his course of dealing. Yet it is to be observed, that what the banker's gain percent. of all the money ad-

venturel at *buffet*, is greater than that at *buffet*; it being two pounds sixteen shillings and ten-pence per cent. in the first, and but fifteen shillings and three-pence in the second. Vide *D. Mo v. Dente. Chanc.* p. 93.

BANKER, in *Commerce*, a person who traffics in money, and retains it from place to place, and supplies his correspondents or customers with money from the stock deposited in his hands for bills of exchange and other securities. (See **BANK**.) The history of private banks is as follows. The royal mint in the tower of London had for some years, before the year 1640, been made use of as a kind of bank, or deposit, for merchants to lodge their cash in. But king Charles the first having in that year made free with their money, the mint lost its credit. After this, the merchants and traders of London generally trusted their cash with their servants, until the breaking out of the civil war, when it was very customary for apprentices and clerks to leave their masters and go into the army. Whereupon, in such unsettled times, merchants, not daring longer to confide in their apprentices, began first, about the year 1645, to lodge their necessary cash in goldsmith's hands, both to receive and pay for them; until which time, the whole and proper business of London goldsmiths was to buy and sell plate, and foreign coins of gold and silver, to melt and cull them, to coin some at the mint, and with the rest to supply the refiners, plate-makers, and merchants, as they found the price to vary. This account of the matter we have from a scarce and most curious small pamphlet, published in 1676, intitled, "The Mystery of the new-fashioned Goldsmiths, or Bankers, discovered," in only eight quarto pages.

Bankers on their first establishment allowed to those who entrusted their money in their hands a moderate interest for the same, and hereby their business was very considerably increased, and rose to great reputation in the year 1667, when the Dutch burnt our ships at Chatham; but this event caused a *run* on the bankers, which hurt their credit; and in the year 1672, king Charles II. shut up the exchequer, and seized the money which the bankers had lent him at 8 per cent. interest, the whole sum amounting to 1,328,526 l. The king was afterwards necessitated to pay six per cent. interest for this debt out of his hereditary excise, but the principal was never paid. However, the parliament of 12 William, cap. 12. provided for a large arrear of interest, and settled an interest of three per cent. for the future. The debt was hereby made redeemable, on paying one moiety of the principal sum, viz. 664,263 l. farther confirmed by an act of 2 & 3 Anne, cap. 15. which moiety now became the proper debt of the public; and being reduced from six to five per cent. in 1717, was finally subscribed into the South-sea capital stock in the year 1720.

Bankers now allow no interest, and by investing a certain proportion of their capital in the funds, or laying it out on other sufficient security, and trafficking with it in the stocks, in discounts, &c. reap very considerable advantage from it; and by negotiating bills, &c. on the part of their creditors, greatly contribute to the convenience and dispatch of businesses.

When the people of any particular country, says Dr. Smith (*ubi supra*), have such confidence in the fortune, probity, and prudence of a particular banker, as to believe that he is always ready to pay upon demand such of his promissory notes as are likely to be at any time presented to him, those notes come to have the same currency as gold and silver money, from the confidence that such money can at any time be had for them.

A particular banker lends among his customers his own promissory notes, to the extent, we shall suppose, of a hundred

dred thousand pounds. As those notes serve all the purposes of money, his debtors pay him the same interest as if he had lent them so much money. This interest is the source of his gain. Though some of those notes are continually coming back upon him for payment, part of them continue to circulate for months and years together. Though he has generally in circulation, therefore, notes to the extent of a hundred thousand pounds, twenty thousand pounds in gold and silver may, frequently, be a sufficient provision for answering occasional demands. By this operation, therefore, twenty thousand pounds in gold and silver perform all the functions which a hundred thousand could otherwise have performed. The same exchanges may be made, the same quantity of consumable goods may be circulated and distributed to their proper consumers, by means of his promissory notes, to the value of a hundred thousand pounds, as by an equal value of gold and silver money. Eighty thousand pounds of gold and silver, therefore, can, in this manner, be spared from the circulation of the country; and if different operations of the same kind should, at the same time, be carried on by many different banks and bankers, the whole circulation may thus be conducted with a fifth part only of the gold and silver which would otherwise have been requisite.

Let us suppose, for example, that the whole circulating money of some particular country amounted, at a particular time, to one million sterling, that sum being then sufficient for circulating the whole annual produce of their land and labour. Let us suppose too, that some time thereafter, different banks and bankers issued promissory notes, payable to the bearer, to the extent of one million, reserving in their different coffers two hundred thousand pounds for answering occasional demands. There would remain, therefore, in circulation, eight hundred thousand pounds in gold and silver, and a million of bank notes, or eighteen hundred thousand pounds of paper and money together. But the annual produce of the land and labour of the country had before required only one million to circulate and distribute it to its proper consumers, and that annual produce cannot be immediately augmented by those operations of banking. One million, therefore, will be sufficient to circulate it after them. The goods to be bought and sold being precisely the same as before, the same quantity of money will be sufficient for buying and selling them. The channel of circulation, if I may be allowed such an expression, will remain precisely the same as before. One million we have supposed sufficient to fill that channel. Whatever, therefore, is poured into it beyond this sum, cannot run in it, but must overflow. One million eight hundred thousand pounds are poured into it. Eight hundred thousand pounds therefore must overflow, that sum being over and above what can be employed in the circulation of the country. But though this sum cannot be employed at home, it is too valuable to be allowed to lie idle. It will, therefore, be sent abroad, in order to seek that profitable employment which it cannot find at home. But the paper cannot go abroad: because at a distance from the banks which issue it, and from the country in which payment of it can be exacted by law, it will not be received in common payments. Gold and silver, therefore, to the amount of eight hundred thousand pounds, will be sent abroad, and the channel of home circulation will remain filled with a million of paper, instead of a million of those metals which filled it before.

But though so great a quantity of gold and silver is thus sent abroad, we must not imagine that it is sent abroad for nothing, or that its proprietors make a present of it to foreign nations. They will exchange it for fo-

reign goods of some kind or another, in order to supply the consumption either of some other foreign country, or of their own.

If they employ it in purchasing goods in one foreign country in order to supply the consumption of another, or in what is called the carrying trade, whatever profit they make will be an addition to the neat revenue of their own country. It is like a new fund, created for carrying on a new trade; domestic business being now transacted by paper, and the gold and silver being converted into a fund for this new trade.

If they employ it in purchasing foreign goods for home consumption, they may either, first, purchase such goods as are likely to be consumed by idle people who produce nothing, such as foreign wines, foreign silks, &c.; or, secondly, they may purchase an additional stock of materials, tools, and provisions, in order to maintain and employ an additional number of industrious people, who re-produce, with a profit, the value of their annual consumption.

So far as it is employed in the first way, it promotes prodigality, increases expence and consumption, without increasing production, or establishing any permanent fund for supporting that expence, and is in every respect hurtful to society.

So far as it is employed in the second way, it promotes industry; and though it increases the consumption of the society, it provides a permanent fund for supporting that consumption, the people who consume, re-producing, with a profit, the whole value of their annual consumption. The gross revenue of the society, the annual produce of their land and labour, is increased by the whole value which the labour of those workmen adds to the materials upon which they are employed; and their neat revenue by what remains of this value, after deducting what is necessary for supporting the tools and instruments of their trade. Smith's Wealth of Nations, vol. i. p. 434, &c.

In Italy, the employment of a banker, especially in republics, does not derogate from nobility; and hence it is, that most of the cadets, or younger sons of persons of condition, undertake it for the support of their family. The nobility of Venice and Genoa were for a long time the chief bankers in the other countries of Europe.

The ancient bankers were called *argentarii*, and *nummularii*; and by the Greeks *ταρταριται*, *καθημεριται*, and *αγοραμοιστοι*. Their chief business was to put out the money of private persons to interest; they had their boards and benches for this purpose in all the markets and public places, where they took in the money from some to lend it to others. The Romans had two kinds of bankers, though their office was much more extensive than that of the bankers among us, theirs being that of public officers, in whom were united the functions of a broker, agent, banker, and notary; managing the exchange, taking in money, assisting in buying and selling, and drawing up the writings necessary on all these occasions.

BANKERS in the Court of Rome, are persons authorized, exclusive of all others, to solicit and procure by their correspondents at Rome, all bulls, dispensations, and other acts dispatched at the papal datary, or in the legateship of Avignon; they are dispersed in all the cities of France, where there is a parliament, or a presidial; and were erected into a regular and hereditary office, by an edict in 1673.

They owe their origin to the Guelfs, who took shelter at Avignon, and in other cities within the obedience of the pope, in the time of the civil wars in Italy. The favour they were in with the pontiffs, for having espoused the pa-

pal cause, occasioned their being employed in procuring expeditions of the court of Rome. But the heavy extortions they practised toward their clients, soon rendered them odious, and occasioned several denominations of reproach, as *carcini*, *catuicini*, *causfici cogiti*, &c. from the city Cahors, the native place of pope John XXII. in whose pontificate they were in their highest power.

BANKER, in *Bricklaying*, a piece of timber whereon they cut the bricks.

The banker is six feet long or more, according to the number of men to work at it, and nine or ten inches square: it is to be laid on two piers of timber, three feet high from the floor they stand on.

BANKER, in *Sea Language*, signifies a vessel employed in the cod-fishery on the banks of Newfoundland.

BANKES, Sir JOHN, in *Biography*, lord chief justice of the common pleas in the reign of king Charles I. was descended from a good family at Kefwick in Cumberland, and born there in the year 1589. In 1624 he removed to Queen's college, Oxford, and afterwards pursued the study of the law in Gray's inn. By his application and proficiency he acquired a reputation which recommended him to his sovereign Charles I. who, in 1629, made him his attorney. In August 1634, he was knighted, and appointed to the office of attorney general; from which office he was advanced, in 1640, to that of chief justice of the common pleas. In both these offices he acted with wisdom and integrity, and obtained universal approbation. So singular was his merit, that, though he decidedly took part with the king in his contest with the parliament, it was desired by the latter, in 1643, that he might be continued in office. However, he soon after lost all his credit at Westminster; for he declared from the bench at Salisbury, that the actions of Essex, Manchester, and Waller, were treasonable; and the commons voted him and the rest of the judges who were of this opinion, traitors. Lady Bankes manifested extraordinary fortitude in the defence of Corff castle in the isle of Purbeck, where sir John and his family resided. When it was besieged by the parliamentary forces, she refused to surrender it, though she had about her only her children, a few servants and tenants, amounting at one time only to five and at most to no more than forty. When the town was obliged to surrender, and the besiegers became remiss under a notion that their business was completed, lady Bankes procured a supply of provision and ammunition, and was thus enabled to hold out till the siege was raised. Sir John remained with the king at Oxford, in the discharge of his duty as a privy-counsellor, till his death, which happened in December 1644. By his will he bequeathed, besides other charities, an annuity of thirty pounds to the town of Kefwick for the support of a manufacture of coarse cottons, which had been lately established, and which, without this aid, would have been lost. Sir John Bankes was distinguished by sound integrity, cool judgment, and an amiable temper. *Biog. Brit.*

BANKIANA, in *Entomology*, a species of *PHALÆNA Torvica*, named after sir Joseph Banks; it inhabits the woods of England and Germany: is of a large size; and is distinguished by having the wings brown, with two snowy white bands, the posterior one unidentate. *Fabricius.*

BANKING, in general, the making of banks to oppose the force of the sea, rivers, or the like, and secure the land from being overflowed thereby.

With respect to the water which is to be kept out, this is called banking; with respect to the land, which is hereby to be defended, imbanking.

BANKING, in a *Salt-Work*, the raising a fence against the

sea, whereby its waters may be kept out, excepting so much as is necessary for the preparation of the salt.

BANKING, in *Commerce*. See **BANK**, and **BANKER**.

BANKOK, or **BANCOK**, in *Geography*, a town of Siam, at the mouth of the river Meimam, which discharges itself into the gulf of Siam.

BANKRUPT, in *Commerce* and *Law*, a trader, who sequesters himself, or does certain other acts, tending to defraud his creditors.

The word is formed from the ancient Latin *bancus*, a bench, or table, and *ruptus*, broken.

Bank, we have elsewhere observed, originally signified a bench, which the first bankers had in the public places, in markets, fairs, &c. on which they told their money, wrote their bills of exchange, &c. Hence, whence a banker failed, they broke his bank, to advertise the public, that the person to whom the bank belonged was no longer in a condition to continue his business. As this practice was very frequent in Italy, it is said the term bankrupt is derived from the Italian *banco rotto*, broken bench.

Cowel rather chuses to deduce the word from the French *banque*, table, and *route*, vestigium, trace, by metaphor from the sign left in the ground, of a table once fastened to it and now gone. On this principle he traces the origin of bankrupts from the ancient Roman *mensarii*, or *argentarii*, who had their *tabernæ* or *mensæ* in certain public places; and who, when they fled, or made off with the money that had been trusted to them, left only the sign or shadow of their former station behind them. 4 *Inst.* 277.

And it is observable, that the title of the first English statute concerning this offence, 34 Hen. VIII. cap. 4. "against such persons as do make bankrupt," is a literal translation of the French idiom *qui font banque route*.

A bankrupt was formerly considered merely as a criminal or offender (*stat. 1. Jac. I. c. 15. § 17.*); but at present the laws of bankruptcy are regarded as laws calculated for the benefit of trade, and founded on the principles of humanity as well as justice: and to that end, they confer some privileges, not only on the creditors, but also on the bankrupt himself:—on the creditors, by compelling the bankrupt to give up all his effects to their use, without any fraudulent concealment;—and on the debtor, by exempting him from the rigour of the general law, whereby his person might be confined at the discretion of his creditor, though in reality he has nothing to satisfy the debt; whereas the law of bankrupts, taking into consideration the sudden and unavoidable accidents to which men in trade are liable, has given them the liberty of their persons, and some pecuniary emoluments, upon condition of surrendering their whole estate to be divided among the creditors.

By the Roman law of the twelve tables, the creditors might cut the debtor's body into pieces, and each of them take his proportionable share; though some learned men have doubted whether the law "de debitore in parte secando," is to be understood in so very butcherly a light. There were also other laws, less inhuman, for imprisoning the debtor's person in chains, subjecting him to stripes and hard labour, at the mercy of his rigid creditor, and sometimes selling him, his wife and children, to perpetual foreign slavery "trans Tiberim;" but this was an oppression that produced many popular insurrections, and secessions to the "mons sacer." In Pegu, and the adjacent countries in East India, the creditor is entitled to dispose of the debtor himself, and likewise of his wife and children; inasmuch that he may even violate with impunity the chastity of the debtor's wife; but then, by so doing, the debt is understood to be discharged. In some places, bankrupts are condemned to wear

wear a green cap; at Lucca, an orange cap. Our legislators, however, in framing the laws of bankruptcy, seem humanely and wisely to have attended to the example of the Roman law of "Cession," introduced by the Christian emperors; by which, if a debtor ceded or yielded up all his fortune to his creditors, he was secured from being dragged to a gaol; "Omni quoque corporali cruciatus semoto." (Cod. 7. 71. *per tot.*) For as the emperor justly observes (Just. 4. 6. 40.), "inhumanum erat spoliatum fortunæ suis in solidum damnari." But by a deviation into the other extreme, it was afterwards enacted (Nov. 135. c. 1.), that if the debtor by any unforeseen accident was reduced to low circumstances, and would *swear* that he had not sufficient left to pay his debts, he should not be compelled to cede or give up even that which he had in his possession;—a law which, under a false notion of humanity, seems to be fertile of perjury, injustice, and absurdity. The laws of England steer between these extremes; providing at once against the inhumanity of the creditor, who is not suffered to confine an honest bankrupt who has delivered up all his effects, and at the same time taking care that all his just debts shall be paid, so far as the effects will extend. But they are still cautious of encouraging prodigality and extravagance by this indulgence to debtors; and, accordingly, allow the benefit of the laws of bankruptcy to none but actual *traders*, who, generally speaking, are the only persons liable to accidental losses, and to an inability of paying their debts, without any fault of their own. Trade cannot be carried on without mutual credit on both sides; and here the contracting of debts is not only justifiable, but even necessary. And if by accidental calamities, as by the loss of a ship in a tempest, the failure of brother traders, or by the non-payment of persons out of trade, a merchant or trader becomes incapable of discharging his own debts, it is his misfortune and not his fault. To the misfortunes of debtors, therefore, the law has given a compassionate remedy, but denied it to their faults; since, while it provides for the security of commerce, by enacting that every considerable trader may be declared a bankrupt, for the benefit of his creditors as well as himself, it has also, with a view of discouraging extravagance, declared, that no one shall be capable of being made a bankrupt, but only a *trader*; nor capable of receiving the full benefit of the statutes, but only an *industrious* trader.

The first statute made concerning any English bankrupts was 34 Hen. VIII. c. 4. when trade began first to be properly cultivated in England: which has been almost totally altered by statute 13 Eliz. c. 7. whereby bankruptcy is confined to such persons only as have used the trade of merchandise, in gross or by retail, by way of bargaining, exchange, rechange, bartering, chevance, or otherwise; or have sought their living by buying and selling. And by statute 21 Jac. I. c. 19. persons using the trade or profession of a scrivener, receiving other men's monies and estates into their trust and custody, are also made liable to the statutes of bankruptcy; and the benefits, as well as the penal parts of the law, are extended as well to aliens and denizens as to natural born subjects, being intended entirely for the protection of trade, in which aliens are often as deeply concerned as natives. By many subsequent statutes, but lastly by statute 5 Geo. II. c. 30. bankers, brokers, and factors, are declared liable to the statutes of bankruptcy; and this upon the same reason that scriveners are included by the statute of James I. viz. for the relief of their creditors: whom they have otherwise more opportunities of defrauding than any other set of dealers; and they are properly to be looked upon as traders, since they make merchandise of money, in

the same manner as other merchants do of goods and other moveable chattels. But by the same act, no farmer, grazier or drover, shall (as such) be liable to be deemed a bankrupt; for though they buy and sell corn, and hay, and beasts, in the course of husbandry, yet trade is not their principle, but only a collateral object; their chief concern being to cultivate and till the ground, and make the best advantage of its produce. And, besides, the subjecting them to the laws of bankruptcy might be a means of defeating their landlords of the rents by which the law has given them above all others, for the payment of their reserved rents; wherefore also, upon a similar reason, a receiver of the king's taxes is not capable, as such, of being a bankrupt; lest the king should be defeated of the extensive remedies against his debtors, which are put into his hands by the prerogative. By the same statute, no person shall have a commission of bankrupt awarded against him, unless at the petition of some one creditor to whom he owes 100l.; or of two, to whom he is indebted 150l.; or of more, to whom altogether he is indebted 200l. For the law does not look upon persons, whose debts amount to less, to be traders considerable enough, either to enjoy the benefit of the statute themselves, or to entitle the creditors, for the benefit of public commerce to demand the distribution of their effects.

In the interpretation of these several statutes, it hath been held, that buying only, or selling only, will not qualify a man to be a bankrupt: but it must be both buying and selling, and also getting a livelihood by it; as, by exercising the calling of a merchant, a grocer, a mercer, or, in one general word, a chapman, who is one that buys and sells any thing. But no handicraft occupation (where nothing is bought and sold, and where therefore an extensive credit for the stock in trade is not necessary to be had) will make a man a regular bankrupt; as that of a husbandman, a gardener, and the like, who are paid for their work and labour. Also an inn-keeper cannot, as such, be a bankrupt; for his gain or livelihood does not arise from buying and selling in the way of merchandise, but in a great degree from the use of his rooms and furniture, his attendance, and the like; and though he may buy corn and victuals, to sell again at a profit, yet that no more makes him a trader, than a schoolmaster or other person is, that keeps a boarding-house, and makes considerable gains by buying and selling what he spends in the house; and such a one is clearly not within the statutes. But where persons buy goods, and make them up into saleable commodities, as shoe-makers, smiths, and the like; here, though part of the gain is by bodily labour, and not by buying and selling, yet they are within the statutes of bankrupts; for the labour is only in melioration of the commodity, and rendering it more fit for sale.

One single act of buying and selling will not make a man a trader; but a repeated practice, and profit by it. Buying and selling bank-stock, or other government securities, will not make a man a bankrupt; they not being goods, wares, or merchandise, within the intent of the statute, by which a profit may be fairly made. Neither will buying and selling under particular restraints, or for particular purposes; as if a commissioner of the navy uses to buy victuals for the fleet, and dispose of the surplus and refuse, he is not thereby made a trader within the statute. An infant, though a trader, cannot be made a bankrupt; for an infant can owe nothing but for necessaries; and the statutes of bankruptcy create no new debts, but only give a speedier and more effectual remedy for recovering such as were before due; and no person can be made a bankrupt for debts which he is not liable at law to pay. But a feme covert in London, being a sole

trader according to the custom, is liable to a commission of bankrupt.

Having shewn who may, and who may not be made a bankrupt, the next subject of inquiry comprehends the particular acts of bankruptcy which render a man a bankrupt. For full satisfaction on this point, it will be necessary to consult the several statutes, and the resolutions formed upon them by the courts. Among these may be reckoned, 1. Departing from the realm, when by a man withdraws himself from the jurisdiction and coercion of the law, with intent to defraud his creditors. 2. Departing from his own house, with intent to secrete himself, and avoid his creditors. 3. Keeping in his own house, privately, so as not to be seen or spoken with by his creditor, (except for just and necessary cause), which is likewise construed to be an intention to defraud his creditors, by avoiding the process of the law. 4. Procuring or suffering himself willingly to be arrested, or outlawed, or imprisoned, without just and lawful cause; which is likewise deemed an attempt to defraud his creditors. 5. Procuring his money, goods, chattels, and effects, to be attached or sequestered by any legal process; which is another plain and direct endeavour to disappoint his creditors of their security. 6. Making any fraudulent conveyance to a friend, or secret trustee, of his lands, tenements, goods, or chattels; which is an act of the same suspicious nature with the last. 7. Procuring any protection, not being himself privileged by parliament, in order to screen his person from arrests; which also is an endeavour to elude the justice of the law. 8. Endeavouring or desiring, by any petition to the king, or bill exhibited in any of the king's courts against any creditors, to compel them to take less than their just debts; or to procrastinate the time of payment, originally contracted for; which are an acknowledgement of either his poverty or his knavery. 9. Lying in prison for two months, or more, upon arrest or other detention for debt, without finding bail, in order to obtain his liberty. For the inability to procure bail, argues a strong deficiency in his credit, owing either to his suspected poverty, or ill character; and his neglect to do it, if able, can arise only from a fraudulent intention; in either of which cases it is high time for his creditors to look to themselves, and compel a distribution of his effects. 10. Escaping from prison after an arrest for a just debt of 100*l.* or upwards. For no man would break prison that was able and desirous to procure bail; which brings it within the reason of the last case. 11. Neglecting to make satisfaction for any just debt to the amount of 100*l.* within two months after service of legal process, for such debt, upon any trader having privilege of parliament. Stat. 13 Eliz. c. 7. 1 Jac. I. c. 15. 21 Jac. I. c. 19. 4 Geo. III. c. 33.

The legislature having thus by positive laws declared what are the acts which shall be regarded as criterions of insolvency or fraud, on which a commission of bankruptcy may be grounded, our courts of justice will not allow of extending or multiplying acts of bankruptcy by any construction or implication. And, therefore, sir John Holt held (Lord Raym. 725.) that a man's removing his goods privately to prevent their being seized in execution, was no act of bankruptcy. It has also been determined expressly, that a banker's stopping or refusing payment is no act of bankruptcy; and if in consequence of such refusal, he is arrested and puts in bail, it is still no act of bankruptcy (7 Mod. 139.); but if he goes to prison, and lies there two months, then, and not before, he is become a bankrupt.

The proceedings in a commission of bankrupt, depend entirely on the several statutes of bankruptcy; and they are digested by Blackstone into the following concise order.

And, first, there must be a petition to the lord chancellor by one creditor to the amount of 100*l.*, or by two to the amount of 150*l.*, or by three or more to the amount of 200*l.*; which debts must be proved by affidavit: upon which he grants a commission to such discreet persons as to him shall seem good, who are then styled commissioners of bankrupt. The petitioners, to prevent malicious applications, must be bound in a security or bond to the lord chancellor of 200*l.*, to make the party amends in case they do not prove him a bankrupt. And if on the other hand they receive any money or effects from the bankrupt, as a recompence for suing out the commission, so as to receive more than their rateable dividends of the bankrupt's estate, they forfeit not only what they shall have so received, but their whole debt. These provisions are made, as well to secure persons in good credit from being damaged by malicious petitions, as to prevent knavish combinations between the creditors and bankrupt, in order to obtain the benefit of a commission. When the commission is awarded and issued, the commissioners are to meet, at their own expense, and to take an oath for the due execution of their commission, and to be allowed a sum not exceeding 20*s.* per diem each, at every sitting. And no commission of bankrupt shall abate, or be void, by the death of the bankrupt, subsequent to the commission, stat. 1 Jac. I. c. 15.; nor upon any demise of the crown, stat. 5 Geo. II. c. 30. The granting of a commission of bankruptcy is not discretionary, but a matter of right. 1 Vern. 153. Stat. 13 Eliz. c. 7.

When the commissioners have received their commission, they are first to receive proof of the person's being a trader, and having committed some act of bankruptcy; and then to declare him a bankrupt, if proved so; and to give notice thereof in the gazette, and at the same time to appoint three meetings. At one of these meetings an election must be made of assignees. And at the third meeting, at farthest, which must be on the forty-second day after the advertisement in the gazette (unless the time be enlarged by the lord chancellor), the bankrupt, upon notice also personally served upon him or left at his usual place of abode, must surrender himself personally to the commissioners; which surrender (if voluntary) protects him from all arrests till his final examination is past: and he must thenceforth in all respects conform to the directions of the statutes of bankruptcy; or, in default of either surrender or conformity, shall be guilty of felony without benefit of clergy, and shall suffer death, and his goods and estate shall be distributed among his creditors. Stat. 5 Geo. II. c. 30.

In case the bankrupt absconds, or is likely to run away, between the time of the commission issued, and the last day of surrender, he may by warrant from any judge or justice of the peace be apprehended and committed to the county goal, in order to be forthcoming to the commissioners; who are also empowered immediately to grant a warrant for seizing his goods and papers. Stat. 5 Geo. II. c. 30.

When the bankrupt appears, the commissioners are to examine him touching all matters relating to his trade and effects. They may also summon before them, and examine the bankrupt's wife, and any other person who soever, as to all matters relating to the bankrupt's affairs. And in case any of them shall refuse to answer, or shall not answer fully to any lawful question, or shall refuse to subscribe such their examination, the commissioners may commit them to prison without bail, till they submit themselves and make and sign a full answer; the commissioners specifying in their warrant of commitment the question so refused to be answered.

ferred. And any gaoler, permitting such person to escape, or to go out of prison, shall forfeit 500*l.* to the creditors. Stat. 21 Jac. I. c. 19. 5 Geo. II. c. 30.

The bankrupt, upon this examination, is bound upon pain of death to make a full discovery of all his estate and effects, as well in expectancy as possession, and how he has disposed of the same; together with all books and writings relating thereto: and is to deliver up all in his own power to the commissioners (except the necessary apparel of himself, his wife, and his children); or, in case he conceals or embezzles any effects to the amount of 20*l.* or withholds any books or writings, with intent to defraud his creditors, he shall be guilty of felony without benefit of clergy; and his goods and estate shall be divided among his creditors. And unless it shall appear, that his inability to pay his debts arose from some casual loss, he may, upon conviction by indictment of such gross misconduct and negligence, be set upon the pillory for two hours, and have one of his ears nailed to the same and cut off. Stat. 5 Geo. II. c. 30. 21 Jac. I. c. 19.

After the time allowed to the bankrupt for such discovery is expired, any other person voluntarily discovering any part of his estate, before unknown to the assignees, shall be entitled to 5 per cent. out of the effects so discovered, and such farther reward as the assignees and commissioners shall think proper. And any trustee, wilfully concealing the estate of any bankrupt, after expiration of the two and forty days, shall forfeit 100*l.* and double the value of the estate concealed to the creditors. Stat. 5 Geo. II. c. 30.

Hitherto every thing is in favour of the creditors; and the law seems to be pretty rigid and severe against the bankrupt; but, in case he proves honest, it makes him full amends for all this rigour and severity. For if the bankrupt hath made an ingenious discovery (of the truth and sufficiency of which there remains no doubt), and hath conformed in all points to the directions of the law; and if, in consequence thereof, the creditors, or four parts in five of them in number and value (but none of them creditors for less than 20*l.*), will sign a certificate to that purport; the commissioners are then to authenticate such certificate under their hands and seals, and to transmit it to the lord chancellor: and he, or two of the judges whom he shall appoint, on oath made by the bankrupt that such certificate was obtained without fraud, may allow the same; or disallow it, upon cause shewn by any of the creditors of the bankrupt. Stat. 5 Geo. II. c. 30.

If no cause be shewn to the contrary, the certificate is allowed of course; and then the bankrupt is entitled to a decent and reasonable allowance out of his effects, for his future support and maintenance, and to put him in a way of honest industry. This allowance is also in proportion to his former good behaviour, in the early discovery of the decline of his affairs, and thereby giving his creditors a larger dividend. For, if his effects will not pay one half of his debts, or ten shillings in the pound, he is left to the discretion of the commissioners and assignees, to have a competent sum allowed him, not exceeding 3 per cent.; but if they pay ten shillings in the pound, he is to be allowed 5 per cent.; if twelve shillings and sixpence, then 7½ per cent.; and if fifteen shillings in the pound, then the bankrupt shall be allowed 10 per cent.: provided, that such allowance do not in the first case exceed 250*l.*, in the second 250*l.*, and in the third 300*l.* Stat. 5 Geo. II. c. 30.

Besides this allowance, he has also an indemnity granted him, of being free and discharged for ever from all debts owing by him at the time he became a bankrupt; even

though judgement shall have been obtained against him, and he lies in prison upon execution for such a debt; and, for that among other purposes, all proceedings on commissions of bankrupt are, on petition, to be entered of record, as a perpetual bar against actions to be commenced on this account: though, in general, the production of a certificate properly allowed shall be sufficient evidence of all previous proceedings. Stat. 5 Geo. II. c. 30.

The certificate, when allowed, will not discharge the creditors of a bankrupt: but if he obtains it before his debts are fixed, it will discharge them: whereas if not till after they are fixed, they will remain liable notwithstanding the certificate: and if the creditor prove his debt, with intent to obstruct the certificate, it does not preclude him from pursuing his legal remedy: and even if he had received his debt or part of it, under the commission, still he might proceed to fix the bail who would be entitled to their remedy, so far as they are oppressed, by "audita querela" or by "motion." (1 Atk. 94. 1 Burr. 234. 2 Burr. 716.) The certificate does not discharge a bankrupt from his own express collateral covenant, which does not run with the land (2 Burr. 2442.); nor from a covenant to pay rent. (4 Term Rep. 94.) A bankrupt, after a commission of bankruptcy tied out, may, in consideration of a debt due before the bankruptcy, and for which the creditor agrees to accept no dividend or benefit under the commission, make such creditor a satisfaction, in part, or for the whole of his debt, by a new undertaking or agreement; and "assumpsit" will lie upon such new promise or undertaking. (1 Atk. 67.) Although a creditor of a bankrupt under 20*l.* is excluded from assent or dissent to the certificate, yet as he is affected by the consequence of allowing the certificate, he has a right to petition and shew any fraud against allowing the certificate. 7 Vin. Abr. 134. pl. 18.

No allowance or indemnity shall be given to a bankrupt, unless his certificate be signed and allowed: and also, if any creditor produces a fictitious debt, and the bankrupt does not make discovery of it, but suffers the said creditors to be imposed upon, he loses all title to those advantages. Neither can he claim them, if he has given with any of his children above 100*l.* for a marriage portion, unless he had at that time sufficient left to pay all his debts; or if he has lost at any one time 5*l.* or in the whole 100*l.* within a twelve-month before he became bankrupt, by any manner of gaming or wagering whatsoever; or, within the same time has lost to the value of 100*l.* by speculation. Also to prevent the too common practice of neglect and fraudulent or careless breaking, a mark is set upon such as have been once cleared by a commission of bankrupt, or have compounded with their creditors, or have been delivered by an act of mercy. Persons who have been once cleared by any of these methods, and afterwards become bankrupts again, unless they pay full fifteen shillings in the pound, are only thereby indemnified as to the confinement of their bodies; but any future debts they shall acquire remains liable to their creditors, excepting their necessary apparel, household goods, and the tools and implements of their trades. Stat. 5 Geo. II. c. 30. 24 Geo. 2. c. 57.

By the statute 13 Eliz. c. 7. the commissioners for that purpose, when a man is declared a bankrupt, shall have full power to dispose of all his lands and tenements, which he had in his own right at the time when he became a bankrupt, or which shall descend or come to him at any time afterwards, if these his debts are satisfied or agreed to by him: all lands and tenements which were purchased by him

jointly with his wife or children to his own use (or such interest therein as he may lawfully part with), or purchased with any other person upon secret trust for his own use; and to cause them to be appraised to their full value, and to sell the same by deed indented and enrolled, or divide them proportionably among the creditors. This statute expressly included not only free, but customary and copyhold, lands: and the lord of the manor is thereby bound to admit the assignee (Cro. Car. 568. 1 Atk. 96.): but did not extend to estates-tail, farther than for the bankrupt's life; nor to equities of redemption on a mortgaged estate, wherein the bankrupt has no legal interest, but only an equitable reversion. Whereupon the statute 11 Jac. I. c. 19. enacts, that the commissioners shall be empowered to sell or convey, by deed indented and enrolled, any lands or tenements of the bankrupt, wherein he shall be seized of an estate-tail in possession, remainder, or reversion, unless the remainder or reversion thereof shall be in the crown; and that such sale shall be good against all such issues in tail, remaindermen, and reversioners, whom the bankrupt himself might have barred by a common recovery, or other means: and that all equities of redemption upon mortgaged estates, shall be at the disposal of the commissioners; for they shall have power to redeem the same, as the bankrupt himself might have done, and after redemption to sell them. And the commissioners may sell a copyhold entailed by custom. (Stone 127. Billing 148.) And also, by this and a former act, all fraudulent conveyances to defeat the intent of these statutes are declared void; but that no purchaser *bona fide*, for a good or valuable consideration, shall be affected by the bankrupt laws, unless the commission be sued forth within five years after the act of bankruptcy committed. 1 Jac. I. c. 15.

By virtue of these statutes a bankrupt may lose all his real estates; which may at once be transferred by his commissioners to their assignees, without his participation or consent. See ASSIGNEES.

The property vested in the assignees is the whole that the bankrupt had in himself, at the time he committed the first act of bankruptcy, or that has been vested in him since, before his debts are satisfied or agreed for. And therefore, if a commission is afterwards awarded, the commission and the property of the assignees shall have a relation, or reference, back to the first and original act of bankruptcy. Inasmuch that all transactions of the bankrupt are from that time absolutely null and void, either with regard to the alienation of his property, or the receipt of his debts from such as are privy to his bankruptcy; for they are no longer his property or his debts, but those of the future assignees. If a banker pay the draft of a trader keeping cash with him, after knowledge of an act of bankruptcy, the assignees may recover the money. (2 Term Rep. 113. 3 Bro. C. R. 313.) And if an execution be sued out, but not served and executed on the bankrupt's effects till after the act of bankruptcy, it is void as against the assignees. But the king is not bound by this fictitious relation, nor is within the statutes of bankrupts; for it, after the act of bankruptcy committed and before the assignment of his effects, an extent issues for the debt of the crown, the goods are bound thereby. As these acts of bankruptcy may sometimes be secret to all but a few, and it would be prejudicial to trade to carry this notion to its utmost length, it is provided by statute 19 Geo. II. c. 52. that no money paid by a bankrupt to a *bona fide* or real creditor, in a course of trade, even after an act of bankruptcy done, shall be liable to be refunded. Nor, by statute 1 Jac. I. c. 15. shall any debtor of a bankrupt, that pays him his debt,

without knowing of his bankruptcy, be liable to account for it again. The intention of this relative power being only to reach fraudulent transactions, and not to distress the fair trader.

Sale of goods by a bankrupt, after an act of bankruptcy, is not merely void; the contract is good between the parties; but it may be avoided by the commissioners or assignees at pleasure; so that they may either bring trover for the goods, as supposing the contract may be void, or may bring debt or assumpsit for the value, which affirms the contract. (3 Salk. 59. pl. 2. 2 T. R. 143. 4 T. R. 216. 7.) And so if a bankrupt on the eve of bankruptcy fraudulently deliver goods to a creditor. (4 Term. Rep. 211.) The assignees after four, and within twelve months after the commission issued, must give twenty-one days notice to the creditors of a meeting for a dividend; at which time they must produce their accounts, and verify them upon oath, if required. And then the commissioners shall direct a dividend to be made, at so much in the pound, to all creditors who have before proved, or shall then prove, their debts. This dividend must be made equally, and in a rateable proportion, to all the creditors, according to the quantity of their debts; no regard being had to the quality of them. Mortgages indeed, for which the creditor has a real security in his own hands, are entirely safe; for the commission of bankruptcy reaches only the equity of redemption. So are also personal debts, where the creditor has a chattel in his hands, as a pledge or pawn for the payment, or has taken the debtor's lands or goods in execution. And, upon the equity of the statute 8 Ann. c. 14. (which directs, that, upon all executions of goods being on any premises demised to a tenant, one year's rent and no more shall, if due, be paid to the landlord) it hath also been held, that under a commission of bankrupt, which is in the nature of a statute-execution, the landlord shall be allowed his arrears of rent to the same amount, in preference to other creditors, even though he hath neglected to distrain, while the goods remained on the premises: which he is otherwise entitled to do for his entire rent, be the quantum what it may. But, otherwise, judgments and recognizances (both which are debts of record, and therefore at other times have a priority), and also bonds and obligations by deed or special instrument (which are called debts by specialty, and are usually the next in order), these are all put on a level with debts by mere simple contract, and all paid *pari passu*. Nay, so far is this matter carried, that, by the express provision of the statutes, debts not due at the time of the dividend made, as bonds or notes of hand payable at a future day certain, shall be proved and paid equally with the rest, allowing a discount or drawback in proportion. And infurances, and obligations upon bottomry or *respondentia, bona fide* made by the bankrupt, though forfeited after the commission is awarded, shall be looked upon in the same light as debts contracted before any act of bankruptcy Stat. 21 Jac. c. 19. 7 Geo. I. c. 31. 19 Geo. II. c. 32.

Within eighteen months after the commission issued, a second and final dividend shall be made, unless all the effects were exhausted by the first. And if any surplus remains, after selling his estates and paying every creditor his full debt, it shall be restored to the bankrupt. This is a case which sometimes happens to men in trade, who involuntarily, or at least unwarily, commit acts of bankruptcy, by absconding and the like, while their effects are more than sufficient to pay their creditors. And, if any suspicious or malevolent creditor will take the advantage of such acts, and sue out a commission, the bankrupt has no remedy, but must quietly submit to the effects of his own imprudence;

deuce;

dence; except that, upon satisfaction made to all the creditors, the commission may be superceded. This case may also happen, when a knave is desirous of defrauding his creditors, and is compelled by a commission to do them that justice, which otherwise he wanted to evade. And therefore, though the usual rule is, that all interest on debts carrying interest shall cease from the time of issuing the commission, yet, in case of surplus left after payment of every debt, such interest shall again revive, and be chargeable on the bankrupt, or his representatives. Stat. 5 Geo. II. c. 30. 13 Eliz. c. 7.

The first step to be taken towards procuring a commission of bankruptcy is for the petitioning creditor to make an affidavit of his debt before a master in chancery; or if he resides altogether in the country, before a master extraordinary there, to be filed in the secretary of bankrupt's office in London, and exhibited to the commissioners at their first meeting. When the affidavit is sworn, it is carried to the secretary of bankrupt's office, where the party suing for the commission enters into the bond to the chancellor. The clerk of the bankrupts fills up a blank petition in the name of the person that makes the affidavit, and annexes the affidavit and bond to the petition, when he prefers the same to the lord chancellor. This petition is answered in a few days, and the petitioning creditor has a commission without any further trouble. Having got the commission, he must employ one of the messengers to summon a meeting of the major part of the commissioners to open the same, when the petitioning creditor must come prepared to prove his debt, and the party a bankrupt, within the statutes. Upon the commissioners declaring the party a bankrupt, they issue their warrant for seizure of his effects, and the messenger by virtue of it seizes the effects, and continues to keep possession till the commissioners have executed the assignment. The application to enlarge the time for the bankrupt's surrender must be by petition to the great seal, six days at least before the last sitting appointed in the gazette; which petition may be either in the name of the bankrupt or of his assignees. It is usual for the commissioners to recommend, and the creditors to agree, to return the bankrupts their rings, monies, &c. particularly the jewels, &c. of their wives. If the bankrupt does not surrender himself to the commissioners by twelve o'clock at night of the last day given, the messenger warns him so to do by a proclamation made by him in the middle of Guildhall; the commissioners continuing to sit till that time. The certificate when duly signed, together with the attestations of signature, must be lodged with the secretary of bankrupts, and he will give the messenger an authority to the printer of the gazette, to insert an advertisement signifying that the acting commissioners have certified to the great seal, that the bankrupt hath conformed, and that the certificate will be allowed and confirmed, unless cause be shewn to the contrary within twenty-one days from the date of the said advertisement. If no cause be shewn within twenty-one days against the allowance of the certificate, the lord chancellor will allow the same by a subscription upon it. Jacob's Law Dict. by Tomlins, art. *Bankrupt*.

BANKRUPTCY, the act of becoming a bankrupt. (See *BANKRUPT*.) The French make this difference between a *bankruptcy* and a *failure*, that the first is supposed voluntary and fraudulent, and the latter constrained and necessary, by means of accidents, &c.

BANKS'S ISLAND, in *Geography*, an island in the North Pacific ocean, near the west coast of North America, about 60 miles long and 5 broad. It is separated from Pitt's

archipelago by the canal del Principe; and its north point is situated in N. lat. 53° 39'. W. long. 130° 13'.

BANKS'S ISLAND is also an island of the Southern Pacific ocean, about five leagues west of the coast of the north branch of New Zealand islands. It is about twenty-four leagues in compass; its surface is irregular and elevated; and it may be seen at sea at the distance of twelve or fifteen leagues. Its south point is in S. lat. 43° 32'. W. long. 186° 30'.

BANKS, PORT, a harbour on the north-west coast of America, south-easterly from cape Edgecombe, and north-westerly from S. A. Otter sound.

BANKSAL POINT, a point of the river of Belesore, on the coast of Coromandel, known by the English warehouses that are built on it, and by the tomb of a Dutchman who was there interred.

BANKSEA SPECIOSA, Retz. in *Botany*. See *COSTUS SPECIOSA*.

BANKSIA, so named by Linnæus in honour of sir Joseph Banks, president of the Royal Society, who first discovered it in his voyage with captain Cook. Lin. gen. Schreb. n. 191. Suppl. 15. Gært. t. 47. Juss. 79. Clus. *tetrandria monogynia*. Nat. Ord. *aggregate. Proteæ* Juss. Gen. Char. *Cal.* perianth one-leaved, four-cleft, inferior. *Cor.* one-petalled; tube cylindric, very short; border very long, four-parted; parts linear, lanceolate at the tip, internally hollowed by a little cavity, acute. *Siam.* filaments none; anthers four, lanceolate, sessile in the cavity of the parts of the corolla. *Pist.* germ superior, minute; style filiform, stiff, longer than the corolla; stigma pyramidal, acute. *Per.* capsule ovate, or globose, woody, one-celled, two-valved. *Seed.* two, obovate, convex on one side, flat on the other, terminated by a very large membranaceous veinless wing. *Qu.* Is this an *Avillus*?

Ess. Char. *Cal.* four-cleft, inferior. *Cor.* four-parted; tube very short; border very long, linear-lanceolate; anthers sessile in the cavity of the parts of the corolla. *Cap.* two-seeded, one or two-celled, two-valved.

Species, 1. *B. ferrata*, ferrate-leaved banksia. White Voy. 223. fig. 1, 2, 3. *B. conchifera*. Gært. fruct. 221. t. 48. f. 1. "Leaves linear, attenuated into the petiole, equally ferrate, truncate at the end with a point." This is the handsomest species of the genus; trunk thick and rugged; leaves alternate, thick at the ends of the branches, on short petioles, obtuse, ferrate, bright green above, beneath opaque and whitish, with a strong rib running through their middle; each branch terminated by a large cylindrical spike of flowers; the capsules covered with thick down; the flowers and fruits collected into a large globular ament; the seed in each cell of the capsule single, rather large, winged and dark brown. 2. *B. integrifolia*, entire-leaved *B. B. spicata*. Gært. fruct. 221. t. 48. f. 2. "Leaves wedge-form, quite entire, white-tomentose underneath." The flowers and fruits are collected into a cylindrical ament; and before they are ripe, are pubescent with a nap of snowy whiteness; capsule coriaceous, orbiculate at top, turgidly lens-shaped, and continued at bottom into a conical, compressed beak; within black, two-celled, and gaping at the tip. 3. *B. eriocephala*, heath-leaved *B.* "Leaves approximating, acerose, truncate-emarginate, smooth." The leaves are very small, but more abundant than those of the preceding species. 4. *B. dentata*, tooth-leaved *B.* "Leaves oblong, attenuated into the petiole, curved, flexuose, toothed, teeth ending in a spinule, white underneath." The flowers of this species are smaller than in the others. 5. *B. pyriformis*, pear-fruited *B.* "Flowers solitary; capsules ovate, pubescent; leaves

leaves lanceolate, very entire, smooth." The capsules are larger than in any other known species, one-celled, and opening longitudinally on the lower side; there are two seeds of a rufous cinnamon colour, convex on one side and flat on the other, with a large, membranaceous, veined wing. 6. *B. gibbifolia*, gibbous-fruited *B.* *B. dactyloides*, Garta, 221. t. 47. f. 2. "Flowers solitary; capsules ovate, gibbous, wrinkled; leaves columnar." Leaves about two inches long, and one line in diameter, pale green, and smooth. Dr. Smith says that the *B. dactyloides* of Gartner and this are different kinds. 7. *B. multiflorata*, muffle-fruited *B.* "Flowers solitary; capsules ovate-conical, muffle-shaped, pointed, with tubercles on the outside; leaves obovate, emarginate." Leaves alternate, from six to eight inches long, and three broad; flowers in a short simple raceme, in which only one or two fruits ripen; the capsule from one inch to two inches or more in length, woody, with roundish tubercles, variegated brown and rust colour, one-celled; the seeds are two and dark-bay. 8. *B. spinulosa*, prickly-leaved *B.* "Leaves linear-revolute, with a little sharp point, and with spinous denticulation; towards the top." Stem woody and branched; leaves irregularly feathered, closely covering the branches, on very short foot-stalks, green and smooth above, white and downy beneath, ending abruptly, tipped with three small spines, and having several hooked upwards in the margin; flowers thick set in a cylindrical erect spike, coming out in pairs. It differs from *B. urucujolia*, in having leaves at least four times as long, obtuse, but with a small central sharp point from the midrib between two other terminal points, as well as in having a greater or less number of small sharp-hooked lateral teeth towards the end of each leaf. The inhabitants of New South Wales call it "Wattangre." All these plants are natives of that country, except the 7th, which Rumphius observed in Amboina, in 1693. This genus is nearly allied to *Protia* and *Embotrium* in appearance and character, but sufficiently distinguished from both in the fruit. It boasts some of the most specious plants that have been discovered in the South seas, and even in the known world. Those with solitary flowers and one-celled capsules (5, 6, 7.) form a separate genus, which Dr. Smith names *Salisburya*; which see.

Propagation and Culture. Some of the species have flowered and seeded here; they have been increased merely by seeds. These, and the plants in general from the South seas, are hardy, considering their climate, and may be treated much in the same manner with the Cape plants; they exert much air, and flourish best near the front of the dry stove. Martyn's Miller.

BANKSIA, Tree. See *PINELEA*.

BANKSIA Affinis, or *Cusso*, so called by Mr. Bruce after Sir Joseph Banks, an inhabitant of the high country of Abyssinia, and indigenous there. Mr. Bruce, who has described and given a drawing of it, and who represents it as one of the most beautiful and useful trees, says, that he never saw it in the Kolla nor in Arabia, nor in any other part of Asia or Africa. It seldom grows above 20 feet high, and generally inclined; its leaf is about two inches and a quarter long, divided into two by a strong rib; its colour is a deep unvarnished green, very pleasant to the eye, and the fore-part is covered with soft hair or down; it is much indented, and resembles a nettle leaf, only that it is narrower and longer. The leaves grow alternately by pairs upon a branch, terminating with a single leaf at the point; the end of the stalk is broad and strong, like that of a palm-branch; and it opens in the part that is without leaves,

about an inch and an half from the bottom, and from this aperture proceed the leaves. The whole cluster of flowers has very much the shape of a cluster of grapes, and the stalk that supports it encircles the stalk of the grape; the flower itself is of a greenish colour, tinged with purple; when fully blown, it is all together of a deep red or purple; the corolla consists of five petals, with a short pistil in the middle, having a round head, and surrounded by eight stamina of the same form, loaded with yellow farina. The calyx consists of five petals, which much resemble another flower; they are rounded at the top, and nearly of an equal breadth every way. The bark of the tree is smooth, of a yellowish white, interspersed with brown streaks which pass through the whole body of the tree. On the upper part, before the first branch of leaves set out, are rings round the trunk of small filaments, of the consistence of horse-hair; these are generally 14 or 16 in number, and are a very remarkable characteristic belonging to this tree. The tree is always planted near churches for the use of the town or village; and it is very serviceable as an antidote to a disorder to which the Abyssinians of both sexes and at all ages are subject. Every individual once a month evacuates a large quantity of worms of the kind called ascarides; and the method of promoting these evacuations is by infusing a handful of dry Cusso flowers in about two English quarts of bonza, or the beer that is made from teff; after it has been steeped all night, it is next morning fit for use. The seed of this tree is very small, smaller than the semen Santonicum; it is easily shed; and on this account no great quantity of the seed is gathered, and therefore the flower is substituted for it. It is bitter, but much less so than the semen Santonicum. Mr. Bruce conceives that this plant may be found in latitudes 11° or 12° north in the West Indies or America; and having been found a gentle, safe, and efficacious medicine in Abyssinia, it is not doubted but the superior skill of physicians would turn it to the advantage of mankind in general, when used here in Europe. Bruce's Travels, vol. v. Appendix, p. 73—76.

BANKSIA, in *Entomology*, a species of *PAPILIO* (*Nymph.*) with angulated wings; above brown, with a yellowish disk, and a black ocellar spot with a double pupil. Fabricius. This is a native of New Holland, and is the *PAPILIO Jf-mone* of Cramer.

BANKSIA, a species of *SCARABÆUS* (*Melobontha*) described by Fabricius from a specimen in the museum of Sir Joseph Banks. The head and thorax are black; wing-cases villose, and with the legs testaceous; abdomen short and retuse.

BANKSIA, a species of *CIMEX* (*Reduvius*) that inhabits India. It is rufous above, with black wings; abdomen deep black; border rufous. Fabricius.

BANKSIA, a species of *CHRYSOMELA* that inhabits Calabria. It is brassy above, beneath testaceous. Fabricius.

BANKSIA, a species of *CERAMBYX* (*Lamia*), that is found at the cape of Good Hope. It is of a greyish colour; thorax slightly spined; wing-cases speckled with ferruginous, and marked with two obscure bands. Fabricius.

BANILEUGA, or *BANILEUGA*, or *BANLIEU*, in *Middle Age Writers*, the territory within which the jurisdiction of municipal magistrates, or ordinary judges of a city, town, or the like, is confined.

It is thus called, because within this tract they may make their proclamations, prohibitions, and other acts of justice and policy, comprised under the name of *BAN*, or *BANNUM*.

BANN, in *Geography*, a river in Ireland, which rises in the

the northern part of the Mourne mountains, in the county of Down, and swelled by various little brooks, soon becomes a large stream. It takes a serpentine course to the north-west, having many bridges over it, till it comes to Portadown, where it is joined by the Newry canal, and a few miles farther it falls into Lough Neagh at Bannfoot ferry, after running about thirty miles. The waters of this river, which is distinguished by the name of the South or Upper Bann, are esteemed superior to any other for the purpose of bleaching. After passing through Lough Neagh, out of which it breaks at Toome castle, where is a bridge over it, it again expands into a small lake called Lough Beg, the views in which are very pleasing. From this, still keeping a north-west direction, it passes through a country formerly overgrown with immense woods, then forces its way over a ridge of rocks called the Salmon-leap, and having again collected its scattered waters, rushes with an impetuous force into the sea at Bannhaven, a few miles below Coleraine. It is certainly one of the finest rivers in Ireland; and if we include its passage through the lake, runs in the whole near ninety miles, with so pure and limpid a stream, that it has acquired the name of "the silver Bann." The lower or northern part of it, being the only outlet for seven rivers and innumerable streams that pour their tributary waters into Lough Neagh, is broad and rapid; but notwithstanding this, and the ridge of rocks already mentioned, it is thought that it might be rendered navigable, a measure from which great advantages are expected. The salmon caught in this river is very highly esteemed, and the fishery is the greatest in the kingdom. (See COLERAINE.) Campbell's Political Survey. Beaufort's Memoir. Young's Tour, &c.

BANN, the name of a river in the north-eastern part of the county of Wexford, Ireland, which falls into the Slaney near Ferna.

BANN, a township in the county of York, in Pennsylvania.

BANN, or *Ban*, *Bannum*, or *Bannus*, in the *Feudal Law*, a solemn proclamation, or publication of any thing.

The origin of the word is uncertain: some deduce it from the British *ban*, *clamour*, *noise*; others from the Saxon *ban*, a thing spread; whence *ban* and *band*, used for a flag. Bracton mentions *bannus regis* for a proclamation of silence anciently made by the court, before the encounter of the champions in a combat.

BANN is also used for a solemn convocation of the nobility of a province, to attend the king in his army, conformably to their several tenures.

Bann, in this sense, differs from *rear-bann*; as the former respects those who hold mediately of him. But the words are now confounded; and *bann* and *rear-bann* denote a summons to all the feudal tenants, mediate and immediate, to go to war in the king's service.

BANN also denotes the assembly, or body of nobility and gentry thus convoked.

In this sense, they say, the *bann* and *rear-bann* are long in getting into the field; the *bann* and *rear-bann* were assembled, &c.

The French nobility appear to have served the king, in the way of *bann* and *rear-bann*, from the beginning of the monarchy; though the usage was not regularly settled till the time of the investiture of feuds.

BANN is more particularly used to denote a proscription or banishment, for a crime proved; because anciently published by sound of trumpet: or, as Vossius thinks, because those who did not appear at the above mentioned summons were punished by proscription.

Hence, *to put a prince under the Law of the captive*, is to declare him divested of all his dignities.

The sentence only denotes an interdict of all intercourse and offices of humanity with the offender, the form of which seems taken from that of the Romans, who banished persons, by forbidding them the use of fire and water.

Sometimes also cities are put under the imperial *bann*; that is, stripped of their rights and privileges.

BANN also denotes a pecuniary mulct or penalty laid on a delinquent for offending against a *bann*.

BANNS of Marriage are certain solemn notices of matrimonial contracts made, in the parish-church, before the marriage; that if there be any objections to either party or to prior engagements, &c. there may be an opportunity of making them. The publication of *banns* (popularly called *asking in the church*) was intended as an expedient to prevent clandestine marriages; but a licence or dispensation is now easily procured, so that their use is defeated. By the laws of the church, *banns* are to be published thrice, on three distant days, in the places where the parties live, on pain of nullity of marriage; and excommunications are threatened against those, who, knowing impediments, conceal them. (But see 26 Geo. II. cap. 35. and MARRIAGE.) The use of matrimonial *banns* is said to have been first introduced in the Gallican church, though something like it obtained even in the primitive times; and it is this Tertullian is supposed to mean by *trivindina promulgatio*.

BANN is also used for a solemn anathema, or excommunication, attended with curses, &c.

In this sense, we read of *papal banns*, &c.

BANN of God, *bannus Dei*, or the judgment of God. Spelman takes it for excommunication.

BANN is also used for a prohibition.

In which sense, the *bann* of harvest or vintage, &c. in the French customs, imposes a prohibition to reap, or gather the grapes, without the leave of the lord.

The former is now taken away, and the peasant may reap his corn when he pleases; but the latter still remains, persons not being allowed to open the vintage till publication is made by the officer of the place for that purpose.

BANN-Vin, in the *French Customs*, a privilege enjoyed by lords, of selling the wine of their own growth, during a certain time, exclusive of all other persons within the compass of their fees or lordships.

The same right, in some places, extends also to other liquors; and even to hogs, cows, and other animals.

BANNALEC, in *Geography*, a town of France, in the department of Finistère, and chief place of a canton in the district of Quimperlé; 2½ leagues north-west of Quimperlé.

BANNALIS MOLA, or *Bannal-mill*, a kind of feudal service, whereby the tenants of a certain district are obliged to carry their corn to be ground at a certain mill, and to be baked at a certain oven, for the benefit of the lord.

The oldest account of such *bannal-mills* occurs in the eleventh century. Fulbert, bishop of Chartres, and chancellor of France, in a letter to Richard, duke of Normandy, complains, that attempts began to be made to compel the inhabitants of a part of that province to grind their corn at a mill situated at the distance of five leagues. Vid. "Maxima Bibliotheca Veterum Patrum." Lugdun. 1677. tom. xviii. p. 9. Other examples of this species of servitude, in the tenth and thirteenth centuries, may be seen in Du Freine, under "Molendinum Bannale." De la Mare (Traité de la Police, ii. p. 151.) gives an instance, where a lord in affranching

claiming his subjects, A. D. 1248, required of them, in remembrance of their former subjection, and that he might draw as much from them in future as possible, that they should agree to pay a certain duty, and to send their corn to be ground at his mill, their bread to be baked in his oven, and their grapes to be pressed at his wine press. The origin of these servitudes may possibly be accounted for thus: the building of mills was at all times expensive, and undertaken only by the rich; who, to indemnify themselves for the money expended in order to benefit the public, stipulated that the people in the neighbourhood should grind their corn at no other mills than those erected by them.

BANNAR, in *Geography*, a town of Hindostan, in the district of Coorg-wynaud, seated on the upper branch of the Copany river. N. lat. 11° 48'. E. long. 76° 26'.

BANNAT of Temeswar, a district of Upper Hungary, in the circle on the farther side of the Theis, bounded by the rivers Maros, Theis, and Danube, and watered by the Temes, which is joined by the Bag or Beyhe. In 1552, the Turks became masters of it, and retained it at the peace of Karlowitz, in 1699; but lost it, after a possession of 164 years, in 1716; and in 1718, it was formally ceded to the emperor, at the peace of Passarowitz; which cession, one district excepted, which was granted to the Turks, was ratified in 1739, at the treaty of Belgrade. Its government is divided into the civil and military jurisdiction. Its capital is Temeswar. This bannat presents many ridges of considerable height.

BANN-BRIDGE, a market and post-town of the county of Down, province of Ulster, Ireland, which takes its name from a bridge over the river Bann. It is a pleasant town on the road from Dublin to Belfast, and is remarkable for its great linen fairs. Distance north from Dublin 60½ Irish miles.

BANNER, in *Heraldry*, is a small square flag with fringe, fastened to a lance or spear, similar to the standards now borne by the regiments of cavalry, and was always borne in the field before a prince, duke, marquis, earl, viscount, baron, knight of the garter, and knight-banneret.

Ménage derives the word from the Latin *bandum*, a *band*, or *flag*; and supposes *banniere* to have been first written for *bandiere*; which is confirmed by this, that we meet with the word *bunderia*, used, in the same sense, by Latin writers of the barbarous age.

In the reign of Henry VIII. the size of the royal banner was an ell long, and a yard broad; in queen Elizabeth's reign, the length was two yards and a half, and the breadth two yards, besides the fringe; the complement of men to each banner in the field was always one hundred.

BANNER, in *Military Language*. See COLOURS.

BANNERS of the Romans. See SIGNA.

BANNERETS, an ancient order of knights, or feudal lords, who, possessing several large fees, led their vassals to battle, under their own flag, or banner, when summoned thereto by the king.

The word seems formed from *banner*, a square flag, or from *band*, which anciently also denoted a flag.—*Banner* is also called in ancient writers, *militis vexilliferi*, and *vexillarii*, *bannerarii*, *bannarii*, *banderisii*, &c.

Anciently there were two kinds of knights, *great* and *little*, the first whereof were called **BANNERETS**, the second **BACHELORS**; the first composed the upper, the second the middle, nobility.

The banneret was a dignitary allowed to march under his own flag, whereas the *bachelarius eques* followed that of another. Knights bannerets were originally entitled to display

their banners in the field. A knight Banneret must be a gentleman of family, and have land sufficient to enable him to bring into the field fifty men at arms, with the archers and cross-bowmen appertaining thereto, making in the whole one hundred.

Banneret, according to Spelman, was a middle order between a baron and a simple knight; called sometimes also *vexillarius minor*, to distinguish him from the greater, that is, from the baron, to whom alone properly belonged the *jus vexilli*, or privilege of the square flag.

Hence the banneret was also called *bannerettus*, *quasi baro minor*, a word frequently used by English writers in the same sense as banneret was by the French; though neither of them occur before the time of Edward II.

Some will have bannerets to have originally been persons who had some portion of a barony assigned them; and enjoyed it under the title of *baro proximus*, and that with the same prerogatives as the baron himself.

Some again find the origin of bannerets in France; others in Brittany; others in England. These last attribute the institution of bannerets to Conan, lieutenant of Maximus, who commanded the Roman legions in England under the empire of Gratian, in 383. This general, say they, revolting, divided England into forty cantons, and in these cantons distributed forty knights, to whom he gave a power of assembling, on occasion, under their several banners, as many of the effective men as were found in their respective districts; whence they are called bannerets.

However this be, it appears from Froissart, &c. that anciently such of the military men as were rich enough to raise and subsist a company of armed men, and had a right to do so, were called bannerets. Not, however, that these qualifications rendered them knights, but only bannerets; the appellation of knight being only added thereto, because they were simple knights before.

At the ceremony of creation, the king, at the head of his army, after a victory, is surrounded by all the field officers and nobles at court, under the royal standard displayed to receive the intended knight banneret, who is led to the sovereign by two renowned knights or valiant men at arms, having his pennon or guidon of arms in his hand, preceded by the heralds, who proclaim his valiant achievements. The king then says to him, "Advance thy banneret," and commands the ends of his pennon or guidon to be torn off, which then becomes a banner, being square (on which he has his arms and supporters embroidered). The new knight banneret then returns to his tent, accompanied by martial music, and attended by many nobles and field officers, where they are highly entertained. A knight banneret has a right to display his banner in the field. Neither the title nor supporters are hereditary. In the 28th of Edward I. the daily pay of a knight banneret was four shillings and their diet at court; they take precedence of the younger sons of viscounts and barons. The last knight banneret was sir John Smith, by Charles I. after the battle of Edge-hill, where he rescued the royal standard from the rebels.

BANNERET is also the name of an officer, or magistrate of Rome, towards the close of the fourteenth century.

The people of that city, and throughout the territory of the church, during the disputes of the antipopes, had formed a kind of republican government; where the whole power was lodged in the hands of a magistrate, called senator, and twelve heads of quarters, called bannerets, by reason of the banners which each raised in his district.

BANNER-ROLLS, in *Heraldry*, are small flags used at funerals.

BANNIMUS, *q. d. vae banis*, from the obsolete *banis*, the form of expulsion of any member from the university of Oxford, by affixing the sentence up in some public place, as a denunciation or promulgation of it.

BANNOCK, in *Food*, is an oat-cake, kneaded only with water, and baked in the embers. These are common in Lancashire and some other counties.

BANNOCKBURN, in *Geography*, a village of Scotland, in the county of Stirling, where was fought a battle between the English and Scots on the 25th of June 1314, in which the English were defeated with great loss, and by which the independence of Scotland was secured, and Bruce fixed on the throne of the kingdom; and where James III. king of Scotland, was in 1487 overpowered by his subjects, wounded, and soon after murdered by a priest taking his confession: two miles south of Stirling.

BANNOW, the name of a town which formerly existed in the county of Wexford, province of Leinster, Ireland, situated at the south-eastern extremity of a small haven of the same name, formerly called Bagganbun. This is noted as the place at which Robert Fitzstephen, Harvey of Mountmorres, and Maurice of Pendergall (not earl Strongbow, as some accounts erroneously state), the first of the English adventurers, landed in A. D. 1170. It is said by Gualdus Cambrensis, to be a little creek lying in the county of Wexford, near to Feathard a fishing town, the open sea being on the east, and not far from the haven mouth of Waterford on the south. The same writer speaks of it as very unfit for a harbour, and says that it derived its name from that of one of the ships in which the Englishmen arrived. The name Bagganbun is retained in an ancient rhyme:

“At the creek of Bagganbun,
Ireland was lost and won.”

And the place was so noted, that some old writers have even spoken of the whole island by the name of Bannow. Though the town seems never to have arrived at the same consequence that its neighbour Feathard did, it was made a borough and continued to send members until the union. “So late as the year 1626,” says the writer of a letter to Dr. W. Hamilton, “Bannow is registered in the custom-house books of Wexford, as having four streets which paid quit-rent to the crown, and some buildings surrounding the church.” The name of one of these streets, Weavers’ street, indicates some manufacture to have been carried on. “The only remains of it,” continues the latter writer, “which stand visible at this day (1786) are the walls of its church. There is not in or near the site of the former town even one solitary hut. The election for the representatives of the town is held on the walls of an old chimney, adjoining to the church, which tumbled down piecemeal, and forms the council table of that ancient and loyal corporation. Towns die as well as men; the vestiges of Bannow are traced with difficulty amidst heaps of barren sand, and now the privilege which interested some in its continuance having ceased, in a few years it may be entirely forgotten. Its distance south from Dublin is $76\frac{1}{2}$ Irish miles, long. $6^{\circ} 50'$ W. lat. $52^{\circ} 12'$ N. Hollingshead. Transactions of Royal Irish Academy.

BANNUM Capitis, was a mulct paid in cattle.

BANNUS, or **BANUS**, a title anciently given to the governor or viceroy of Croatia, Dalmatia, and Scia-vonia.

BANNUS Episcopalis, was a mulct paid to the bishop by those guilty of sacrilege, or other crimes.

BANONCOURT, in *Geography*, a town of France, in the department of the Meuse, and chief place of a canton

in the district of St. Mihiel, $1\frac{1}{2}$ league north of St. Mihiel.

BANOY, in *Ornithology*, the name given, by the people of the Philippine islands, to a kind of hawk, somewhat larger than our sparrow-hawk, and of a yellowish colour on the back and wings, and white under the belly. It is the most common of all the kinds of hawk in that part of the world, and is a very voracious animal.

BANQUET, in the *Manege*, denotes that small part of the branch of a bridle under the eye, which, being rounded like a small rod, gathers and joins the extremities of the bit to the branch, in such a manner, that the banquet is not seen, but covered by the cap, or that part of the bit next the branch.

BANQUET-Line, is an imaginary line drawn by the bit-makers along the banquet, in forging a bit, and prolonged upwards and downwards, to adjust the designed force or weakness of the branch, in order to make it stiff or easy; for the branch will be hard and strong if the seal-hole be on the outside of the banquet, with respect to the neck; and it will be weak and easy, if the seal-hole be on the inside of the line, taking the centre from the neck.

BANQUETING-Room, or *house*. (See **XENIA**, **SALOON**, &c.) The ancient Romans supped in the atrium of their houses: but, in after-times, magnificent saloons or banqueting-rooms were built for the more commodious and splendid entertainment of their guests. Lucullus had several of these, each distinguished by the name of some god; and there was a particular rate of expence appropriated to each. Plutarch relates (in Lucullum, apud Oper. t. i. p. 519.) with what magnificence he entertained Cicero and Pompey, who went with design to surprize him, by only telling a slave who waited that the cloth should be laid in the Apollo. The emperor Claudius, among others, had a splendid banqueting-room, named Mercury. But every thing of this kind was outdone by the lustre of that celebrated banqueting-house of Nero, called *domus aurea*; which, by the circular motion of its partitions and ceilings, imitated the revolution of the heavens, and represented the different seasons of the year, which changed at every service, and showered down flowers, essences, and perfumes on the guests. Heliogabalus, nevertheless, is said to have improved as much upon Nero, as the latter had done on Lucullus. Senec. Ep. 90.

BANQUETTE, in *Fortification*, is a little foot bank, or an elevation of earth forming a path which runs along the inside of a parapet; by which the musqueteers get up to discover the countercarp, or to fire on the enemies in the moat or in the covert-way.

The banquette is generally between two and three feet high, and three feet broad, and four feet and a half lower than the parapet, having two or three steps to mount it by. Where the parapet is very high, they make a double banquette one over the other.

BANSTEAD, in *Geography*, a village of Surry in England, is celebrated for its pasture downs, and the delicate mutton they produce. The sheep bred here are of a small species, and being fed mostly on the short sweet herbage which abounds with wild thyme, juniper, &c. their flesh is peculiarly rich, and is often sold in the London markets for lamb. (See **SHEEP**.) The soil of these downs consists of chalk, flints, and a thin stratum of blackish mould. Here is an annual horse-race, much frequented by the sporting people of London.

BANSTICKLE, in *Ichthyology*, a name synonymous with prickle-bag, pickle-back, and stickle-back. See **GASTROSTEVUS**.

BANSWALEH, in *Ceography*, a district of Hindostan, situated on the west part of Malwa.

BANSWARA, a town of Hindostan, in the country of Tellingana or Golconda, twenty miles from Indelovoy.

BANSWARAH, a town of Hindostan, in the country of Malwa, 75 miles west of Ougein, and 105 E.N.E. of Amedabad. N. lat. $23^{\circ} 25'$. E. long. $74^{\circ} 25'$.

BANTAM, a sea-port town in the north-west part of the island of Java, and capital of a kingdom. It is situated at the bottom of the bay of the same name, about a quarter of an hour's walk from the sea-side; and lies between two branches of a river that descends from the mountains, in an extensive plain, behind which there is a range of high and massy hills extending far to the southward. Its distance from Batavia is about 13 Dutch miles, each of which is about $3\frac{1}{2}$ English miles. The communication between these places by land is very difficult, and almost impracticable, on account of the thick forests and deep morasses which lie between them; whereas the passage by water, with the advantage of the land and sea-winds, in the light Indian vessels or proas, called flyers, is performed in four hours. The town of Bantam is large, but has no walls or fortifications towards the sea, nor any on the land side, except fort Diamond, in which the king's palace stands. Bantam resembles a grove of cocoa-nut trees rather than a city. The houses are mere huts, walled up with reeds or canes, plaistered with clay, and covered with attap or leaves of palm-trees, and are confusedly dispersed, without any arrangement of streets; and round each of them is a plantation of cocoa-nut trees, the whole being surrounded by a paling of split bamboo, by which every family is wholly separated from its neighbours. The river of Bantam, at its mouth, is about 170 or 180 feet wide, and is very shallow. However, at high water and in spring tides, it is from five to seven feet deep. Above the town it divides into three channels, of which that just mentioned is the middle one; the other two branches run into the sea, about the distance of $1\frac{1}{2}$ league on each side.

The gulph or bay of Bantam, bounded by a point of the same name and that of Pentang, forms a commodious retreat for ships, where a great number may anchor in safety. Within this bay are several small islands, which are all uninhabited, except Pulo-Fanjang, or the Long island, which is the largest and in which some fishermen reside. Fish are plentiful; and the inhabitants prefer one called the kaalkop or bald-head, which has some resemblance to our cod. This bay was formerly famous for being the principal rendezvous of the shipping from Europe in the east. Bantam was the great mart for pepper and other spices, from whence they were distributed to other parts of the world. The chief factory of the English as well as Dutch East India company was settled there. The merchants of Arabia and Hindostan resorted to it. Its sovereigns were so desirous of encouraging trade, by giving security to foreign merchants against the violent and revengeful disposition of the natives, that the crime of murder was never pardoned when committed against a stranger, but might be committed by a foreigner for a fine to the relations of the deceased. This place flourished for a considerable time; but the Dutch having conquered the neighbouring province of Jacatra, where they have since built Batavia, and transferred their principal business to it; and the English having removed to Hindostan and China, Bantam was reduced to a poor remnant of its former opulence and importance. Other circumstances have also accelerated its decline. The bay is so choked up with daily accessions of new earth washed down from the mountains, as well as by coral shoals extending a considerable way to the east, that it is inaccessible at present to vessels of burden.

A fire also destroyed most of the houses; and few have been since rebuilt. With the trade of Bantam the power of its sovereign declined. In his wars with other princes of Java, he called in the assistance of the Dutch; and from that period he became, in fact, their captive. He resides in a palace, built in the European style, within a fort called the Diamond, situated in a large open field, denominated the Pafcebaan, where three roads, leading from different quarters of the town, unite to the westward of the river, and garrisoned by a detachment from Batavia; the commander of which takes his orders, not from the king of Bantam, but from a Dutch governor, who lives in another fort, called Speelwyk, adjoining to the town, on the east side of the river, and nearer to the sea side. The royal palace is an oblong square, 840 feet long, and nearly half as broad; it has regular bastions at the four corners, and several semicircular places of arms on the sides. Stavorus counted 66 pieces of cannon, most of them being brass, and heavy artillery, but old, and few of them fit for service. The Dutch garrison consists of a captain, three subalterns, and 130 privates, who guard the king's person, and keep him always in the company's power. None of his subjects, nor even his sons, are allowed to approach him without the knowledge of the captain of the Dutch military, who keeps up a regular intercourse with the commandant at fort Speelwyk. No Javanese or Bantammer is ever allowed to pass the night within the walls of the fort. The approach to it is by a drawbridge, thrown over the moat; and at the gate of the fort an officer and 24 men mount guard night and day. The walls of the king's seraglio are raised higher than those of the fort, to guard it against the inspection of the curious. When the king's sons arrive at the age of puberty, they are removed from their father, but have each their separate seraglio or harem. All the servants of the palace are women, and even the king's attendant guards are females. However, when he appears in public, he is accompanied by his Bantam life-guards, though they are never admitted within the gates of the fortress, who, besides their side arms, which are crisses or long daggers, are provided with pikes, having very long and broad iron heads; and when the king goes abroad he is likewise attended by a guard of Europeans from the garrison. Besides maintaining a body of native troops, his Bantamese majesty is allowed to keep several small armed vessels, by means of which he maintains authority over some part of the south of Sumatra. His subjects are obliged to sell him all the pepper they raise in either island at a low price, which he has contracted to deliver to the Dutch at a small advance, and much under the marketable value of that commodity. The religion of the kingdom of Bantam is the same with that which prevails in the island of Java, or Mahometan; and the present king joins the spiritual to the temporal power, and is high-priest of this religion; with which, indeed, he blends some of the rites and superstitions of the aboriginal inhabitants of Java; adoring, for instance, the great banyan or Indian fig-tree, which is likewise held sacred in Hindostan, and under which religious rites may be conveniently performed; in the same manner as all affairs of state are actually transacted by the Bantamese, under some shadowy tree, by moonlight.

In the middle of the plain, or Pafcebaan already mentioned, is a large weringa tree, or casuarina equisetifolia, which by its spreading branches, affords an agreeable shade; and at the foot of it a grave, covered with a large blue stone, in which was buried one of the former kings of Bantam. This is regarded by the inhabitants as a very holy place, and held in great veneration. Near this is a building which is used as a place of circumcision for the children

children of the king; and on such occasions, it is hung round and richly decorated with costly tapestry and pieces of cloth. The Pascebaan is likewise the scene of horse-races and similar exercises, in which the courtiers appear on horseback, magnificently apparelled, to contend with the king or his sons; but they always take care to yield the palm of victory to their royal competitors. The mosque or temple stands at the end of a pleasant lawn, is of a square form, with five roofs above one another, decreasing in size and at last terminating in a point, and surrounded by a wall. The spire serves, like the minarets in Turkey, to announce the hours of prayer. Neither Christian nor Pagan may enter this temple upon pain of death.

The chief authority at Bantam, on behalf of the company, is vested in a senior merchant, with the title of commandant, who manages the trade, consisting chiefly in pepper and some cotton yarn. To the commandery of Bantam belong the two residences or factories which the Dutch company possess in the southern part of the island of Sumatra; whence they derive annually a considerable quantity of pepper. At Bantam all heavy goods are weighed by *bhars*, each containing three *picols*, and these last are estimated at 125 lb. Stavorinus and some of his companions were admitted to an audience by the Bantam king. His dress consisted of a long Moorish coat, made of stuff interwoven with gold, and manufactured at Surat, called *soesjes*, which hung down almost to his feet, and the sleeves of which were fastened by a row of small gold buttons. Under this coat, he wore a white shirt, and a pair of drawers reaching down to his heels, of the same stuff as the coat. His head was covered with a round and somewhat sharp-pointed cap, of a violet colour, laced with silver. Behind his chair stood one of his female life-guards, armed with a large gold kris, in a sheath of massy gold, which she held in an elevated position: two female slaves were seated on each side of him on the ground; one held his tobacco-box and his betel-box, both of which were of gold, and when he wanted either, it was handed to him, wrapped in a silk-handkerchief: the other presented a golden-spitting pot to his majesty, whenever he had occasion for it. Pipes and tobacco were presented to the guests, as soon as they were seated, and the table was furnished with all kinds of Indian food, variously dressed. One singular practice is mentioned, which was that of the king's frequently belching during his meal, and it was followed by all the company. This custom, which is an etiquette of the court of Bantam, was designed to shew that each person's appetite was good and the food agreeable, which was pleasing to the king. Bantam is situated in S. lat. $6^{\circ} 20'$. E. long. $105^{\circ} 24'$. Stavorinus's Voyages, vol. i. p. 57—89. Staunton's Embassy to China, vol. i. p. 296—298.

BANTAM-COCK, in *Ornithology*, a variety of the PHASIANUS *Gallus*, or the *gallus pusillus*, tibiis pennatis, pennis posticis elongatis, in the Linnæan system. It much resembles, says Buffon, the rough-footed cock of France. Its feet are covered with feathers, but only on the outside; the plumage of the legs is very long, and forms a sort of boots which reach a considerable way beyond the claws. It is courageous, and resolutely fights with one stronger than itself. Its iris is red; and it is said, that most of this breed have no tuft.

BANTAM-Work, a kind of Indian painting and carving on wood, resembling Japan work, only more gay, and decorated with a great variety of gaudy colours.

Bantam-work is of less value among connoisseurs, though sometimes preferred by the unskilful, to the true Japan work. Formerly it was in greater use and esteem than

at present; and the imitation of it much practised by our Japanners.

There are two sorts of Bantam as well as of Japan work; as, in the latter, some are flat, lying even with the black, and others high, or embossed; so in Bantam-work, some are flat, and others in-cut, or carved into the wood, as we find in many large screens; with this difference, that the Japan artists work chiefly in gold and other metals, and the Bantam generally in colours, with a small sprinkling of gold here and there.

As to the flat Bantam-work, it is done in colours, mixed with gum-water, proper for the thing designed to be imitated. The method of performing the carved or in-cut kind is thus described by an ingenious artist. The wood is first to be primed with whiting and size, so often till the primer lie near a quarter of an inch thick; then it is to be water-plained, i. e. rubbed with a fine wet cloth, and, some time after, brushed very smooth, the blacks laid on, varnished up with a good body, and polished well, though with a gentle hand. This done, the design is to be traced out with vermilion and gum-water, exactly in the manner wherein it is intended to be cut; the figures, trees, buildings, &c. in their due proportions. Then the graver is applied, with other tools of proper shapes, differing according to the workman's fancy. With these he cuts deep or shallow, as is found convenient, but never deeper than the whiting lies; the wood being never to feel the edge of the instrument. Lines or parts of the black are still to be left, for the draperies and other out-lines, and for the distinction of one thing from another; the rule being to cut where the white is, and leave the black untouched. The carving being finished, they then use the pencil, with which the colours are laid into the cut-work. After this, the gold is to be laid in those places which the design requires; for which purpose, a strong thick gum-arabic water is taken, and laid with a pencil on the work; and, while this remains wet, leaf-gold is cut with a sharp smooth-edged knife, in little pieces, shaped to the bigness and figure of the places where they are to be laid. These being taken up with a little cotton, they dab them with the same clove to the gum-water, which affords a rich lustre. The work thus finished, they clear up the black with oil, taking care not to touch the colours. The European workmen, in lieu of leaf-gold, ordinarily use brass-dust, which is less bright and beautiful. Park. Treat. of Japan.

BANTAYAN, in *Geography*, a small island of the East Indies, belonging to the group of Philippines, situate north-east of Zebu, near cape Durulaque. It is encompassed by four or five of a smaller size; and the inhabitants employ themselves in fishing and making cotton hose.

BANTEIA, or **BANTIA**, in *Ancient Geography*, a town of Italy, in Apulia. Plutarch, in his life of Marcellus, speaks of this place in his account of the march of this general against Hannibal: and Horace (Od. iv. lib. 3.) calls the desiles in its vicinity "faltus Bantinos."

BANTEIN, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg; in which is a carpet manufacture.

BANTI, **BRIGIDA GEORGI**, in *Biography*, an opera singer of the first class. In 1777, she was engaged by the proprietors of the pantheon, to supply the place of the Agujari; a measure adopted merely on speculation, upon hearing from Paris of the effects of her fine voice in that capital.

She was the daughter of a *gondoliere* at Venice, and for some time a piazza performer in that city. After this exercise of her natural vocal powers, she sung her way to Lyons, where she performed in coffee-houses for such small

donations as are usually bestowed on itinerant talents in such places. Hence, by the power of song, she was conveyed to Paris, where her voice was so much admired, that, after very little teaching by some of her countrymen whom she met with there, she was permitted to sing at the concert spirituel. Here the applause was so loud, that it soon reached England, and inclined the proprietors of the pantoon to engage her for three seasons, at 800*l.* a year, upon condition that 100*l.* should be deducted each season out of her salary, for the payment of an able master to cultivate her voice. Sacchini was the first appointed to this office; but soon found her so idle and obstinate, that he quitted her as an incurable patient. She was next assigned to signor Piezzi, whose patience was likewise exhausted before she became a perfect singer. In 1779, she returned to Italy as ignorant of music as when she left that country; but from the accuracy of her ear, and power of imitation, she soon improved, more by example than precept or study; and in 1783, we find in musical records that she was engaged at Florence, as first woman, to sing with Marchesi, then at the zenith of his powers and favour. The next year she sang at Turin; then at Milan; and in 1786, she went to Vienna; thence to Warsaw in 1787; and in 1788, first performed at Naples, where the theatre is the largest in Europe, and reckoned the post of honour among singers. And here her favour was so great, that after singing at Milan with Crescentini, and at Venice with Pacchierotti, she was recalled to Naples three several times before the year 1793, when she went to Spain; and at Madrid she seems still to have increased in fame and favour. His Catholic majesty finding that she had a large family of children, which was increased during her residence in Spain, took two off her hands, and promised to have them educated, and to provide for them. It is hardly credible, with a person and voice so entire and well preserved, but she used to declare, that she had had children and miscarriages to the amount of eighteen!

In 1794, on quitting Spain, she returned to England, where she preserved her voice, increased its powers, and her favour with the public, every season, till 1802, when she again returned to her own country; and in November performed at Bologna, in *Antigona*, an opera composed by Bianchi. From Bologna she was invited to Naples for the fourth time; and from Naples was invited to sing at Milan, during the carnival of 1803.

We cannot take our leave of this admirable performer, without declaring, that we never heard a voice of more grateful tone, or more constant in tune; or an execution (as far as she attempted *bravura*) more neat, brilliant, and articulate. The low notes of her voice were mellifluous, rich, and full to an uncommon degree; and in pathetic airs, the tones through her whole compass were truly touching.

Her knowledge of music was inconsiderable, and this she always confessed; that is, she could not sing at sight; but who is ever required in public to sing airs at sight? and whether she was an hour or a week in studying a part, it was the same thing to the audience, as she was always perfect on the stage; so that the inconvenience was all her own.

It has been said that she wanted variety in her embellishments; but few female singers are sufficiently skilled in the laws of counterpoint to invent graces themselves, that shall not break the time or injure the harmony; and we believe that composers must rejoice in such ignorance, as modestly delivers their melodies unsophisticated, disguised, and changed by what are vulgarly termed graces, but which persons of true taste and judgment, with more propriety, denominate ignorance and impertinence.

We long wished the Banti's shake a little more open, but even that wish was gratified before her departure.

And now, quitting the singer, we shall pay our respects to her as an actress; in which faculty she surpassed in grace, dignity, and propriety, all the stage singers whom we remember ever to have seen; and whoever recollects her performance in the opera of *Semiramide*, will not dispute her transcendent merit in that particular; ever attentive to the persons who addressed her in each scene, whether good or bad singers, friends or foes to herself, she never seemed to think them less worthy of her notice than the ladies of her acquaintance in the pit or the boxes.

Her person and figure were good, and her countenance, though not handsome, was expressive, and her features strong and flexible. Upon the whole, we know not whether she gratified us most as a singer or an actress.

BANTON, or **BATAN**, in *Geography*, one of the smaller Philippine islands.

BANTRY, a market and post town of the county of Cork, Ireland, situated at the bottom of the extensive bay called from it, on the east side. It was formerly called the Old town, to distinguish it from a settlement more to the north, where general Ireton caused a fortification to be erected, but when the fort went to decay, it was entirely forsaken. Several years ago, Bantry was a thriving town, on account of the pilchard fishery, several thousand pounds worth of them having been sent to Italy, Spain, and Portugal, and much oil made from them. In 1748 and 1749, there was a great herring fishery, as appears from returns made to the Dublin society, but the town has since fallen into decay. It was however brought into notice by the French fleet going there, and fortifications were erected there to prevent a future surprise. Whiddy island, opposite the town, is remarkable for its fertility and beauty; and Glanganiff, between Bantry and Bear island, is a charming place, the rocks of which are covered with *Arbutus* trees, and plants of different kinds. Bantry is 164 Irish miles S.W. from Dublin. N. lat. 51° 39'. W. long. 9° 20'.

BANTRY Bay, a large harbour in the western part of the county of Cork, Ireland, which is one of the finest in the world, being twenty-six miles long, and from three to five broad. There is in some parts from 30 to 40 fathom water, and the tides move very gently right in and out through the whole bay. There are few strands round it, the coast being all high and stupendous rocks. In this bay, near the entrance, there was an engagement in A. D. 1689, between the French fleet which brought James II. to Ireland, and the British fleet, of very inferior force, under admiral Herbert, when, after engaging some hours, the former got into the bay, and the latter returned to England with very small loss. In 1796, it was fixed as the place of rendezvous for the French force destined to invade Ireland, and some ships arrived there the 22d of December, which caused a great alarm throughout the country, but general Hoche, the commander in chief, with the rest of the fleet, not arriving, they sailed the 27th of the same month, without having attempted to land.

BANUB, a town of Egypt, 52 miles W. N. W. of Mansoura.

BANVILLE, a town of France, in the department of the Calvados, three leagues N. N. W. of Caen, and 2½ E. of Bayeux.

BANY, the name of a river that lies on the south-west coast of Africa. The Dead island is in this river; and the coast runs here east and west from cape Fermosa.

BANYAN TREE, in *Botany*. See **FICUS**.

BANZA,

BANZA, in *Geography*, a town of Africa, in the kingdom of Congo, now called St. Salvador.

BANZEKOW, a town of Germany, in the circle of Lower Saxony, and county of Schwelm.

BAOBAB, in *Natural History*, the name of an African fruit, described by Prosper Alpinus. It is of the size of a lemon, but it resembles a gourd, and contains several black seeds, whose extremities are a little crooked. Its substance also much resembles that of the gourd; and, when first pulsed off, is moist, red, and of a grateful acid taste. The people of Ethiopia, where it is plentiful, are very fond of it, in the scorching heats of summer; and the richer sort add sugar to it, to correct its acidity. It is a great cooler, and very agreeably quenches thirst; and has also some medicinal use, as it is good in contagious and pestilential fevers. The people of Cairo, where the fresh fruit is not to be had, use its pulp dried and powdered; and it is so used at Senegal in pestilential fevers, the dysentery, and bloody flux. The dose is a drachm, taken either in common water, or in an infusion of the plantain.

The baobab tree, the *Adansonia digitata* (see **ADANSONIA**), has been very minutely and accurately described by Mr. Adanson, in the Memoirs of the Academy of Sciences at Paris. It is found at Senegal in Africa; and its bulk is so enormous, that it has more the appearance of a forest than of a single tree. Its trunk, which seldom exceeds twelve feet in height, measures between seventy and eighty feet in circumference, and is crowned with a number of branches, remarkable for their thickness and their length, which is from fifty to sixty feet. They mostly shoot out in an horizontal direction, and give to the trunk the appearance of an hemisphere from sixty to seventy feet high, and about a hundred and forty feet in diameter. The bark is an inch thick, of an ash-coloured grey, greasy to the touch, bright, and very smooth; the outside is covered with a varnish, and the inside is green speckled with red; the wood is white and soft; the leaves are oval, pointed at the end, and about five inches long, and two and a half broad; seven of these are generally attached to one pedicle. The tree produces flowers much larger than any hitherto known; the calyx of the flower consists only of one piece, the lower part of which forms a short tube, which spreads into the shape of a saucer, having its edge divided into five equal parts of a triangular figure. The petals are five in number, of the same length with the calyx. From the same centre, and within the petal, rises a cone, which spreads into about seven hundred filaments, each having a small substance in form of a kidney at the end of it, the convex part of which opens into two cells, which shed a dust, consisting of small white transparent particles. The pistil rises from the centre of the calyx, and consists of an ovary, a stylus, and several stigmata, in number from ten to fourteen. The ovary becomes a very considerable fruit. The tree flowers in July, and the fruit ripens in October and November. The bark and leaves are dried, and powdered by the negroes of Senegal, and used like pepper and salt. Mr. Adanson used it as a preservative from the epidemic fever of the country, and found it of great benefit in promoting perspiration, and tempering the excessive heat of the blood. The woody bark of the fruit, and the fruit itself, supply the negroes with an excellent soap, which they prepare by drawing a ley from the ashes, and boiling it with palm-oil that begins to be rancid. The decaying trunks are hollowed out into burying places for persons most esteemed by the negroes; such as poets, musicians, and buffoons; and their bodies shut up in these trunks become perfectly dry, without rotting, and form a kind of mummies, without the help of

embalment. This is the largest tree in Abyssinia. The wild bees perforate the trunk, which is soft and spongy, and lodge their honey in the holes made in it; and this honey is preferred to any other in Abyssinia. It may be propagated by seeds, procured from the country where it naturally grows. These must be sown in pots and plunged in a hot-bed; and when in about six weeks the plants come up, they should be transplanted into separate pots, filled with light sandy earth, and plunged into a fresh hot-bed, standing thus till they have taken new root; after which they should have free air in warm weather, and be sparingly watered. As the plants advance in growth, they must be raised into larger pots, and kept constantly plunged in the bark-bed, and remain in the stove with other tender exotic plants. In three years, many of them rise to the height of six feet, and put out several lateral branches, and their stems are proportionable; but after four or five years' growth, they are almost at a stand, their annual shoots rarely exceeding two or three inches. Some seeds obtained from Mr. Adanson have succeeded here, and many of the plants grow upwards of twelve or fifteen feet high. Martyn's Miller. The African baobab has been sometimes confounded with the American calabash.

BAOL, or **BAUL**, in *Geography*, a kingdom of Africa, in the country of Senegal, about eighty leagues long and twenty-four wide.

BAOOM, or **APOOM**, one of the newly discovered islands in the Southern Pacific ocean. S. lat. 16° 26'. W. long. 186° 17'.

BAONS, LES, a town of France, in the department of the Lower Seine, 2½ leagues north of Caudebec.

BAPAUME, a town of France, and principal place of a district in the department of the straits of Calais, containing about 4500 inhabitants; three posts south of Arras, and 19½ north of Paris.

BAPHE, in the *Writings of the Ancients*, a word used to express that fine red colour, with which they used to illuminate the capital letters in manuscripts, at the beginning of chapters. It is also called, by some, *encyclum sacra*; and, by others, *coccus* and *cinnabaris*. It was a very elegant colour, and is said to have been prepared of the purple colour taken from the *murex*, and some other ingredients. It was called *encyclum* from its resembling very much the fine bright red used in enamels.

BAPTACA, in *Geography*, a town of North America in the country of New Navarre, forty-five miles E. S. E. of Casa Grand.

BAPTÆ, in *Antiquity*, an effeminate voluptuous kind of priests at Athens, belonging to Cotys or Cotytto, the goddess of wantonness; thus called, from their itated dipplings and washings, by way of purification. It seems, they were to be made very clean and pure, that they might wallow and defile themselves with the less reserve; for their rites were performed in the night, and consisted chiefly of lascivious dances.

Eupolis having composed a comedy to expose them, intitled *βαπτῶν*, they threw him into the sea, to be revenged; and the same fate is also said to have befallen Cratinus, another Athenian poet, who had written a comedy against the baptæ, under the same title.

Others deduce the denomination baptæ, from the practice of dying and painting their bodies, especially their eyebrows, and officiating at the service of their deity with the parade and demureness of women. Juvenal describes them in this light. Sat. ii. ver. 91.

“ Talia secreta coluerunt orgia tædæ
Cecropiam soliti baptæ lassare Cotytto.”

BAPTES,

BAPTES, in *Natural History*, a name given by the ancients to a fossil substance used in medicine; they have left us but very short descriptions of it. Pliny only tells us that it was soft and of an agreeable smell. Hence Agricola judges, that it was probably one of the bitumens.

BAPTISM, in *Theology*; formed from the Greek *βαπτίζω*, of *βαπτω*, *I dip or plunge*; a rite or ceremony by which persons are initiated into the profession of the Christian religion; or, it is the appointed mode by which a person assumes the profession of Christianity, or is admitted to a participation of the privileges belonging to the disciples of Christ. It was by this mode that those who believed the gospel were to be separated from unbelievers, and joined to the visible Christian church; and the rite accompanying it, or washing with water, was probably intended to represent the washing away, or renouncing the impurities of some former state, viz. the sins that had been committed, and the vicious habits that had been contracted: and to this purpose it may be observed, that the profession of repentance always accompanied, or was understood to accompany, the profession of faith in Christ. That our Lord instituted such an ordinance as baptism, is plain from the commission given to the apostles after his resurrection, and recorded in Matth. xxviii. 19, 20. To this rite, there is also an allusion in Mark, xvi. 16. John, iii. 5. Acts, ii. 41. viii. 12, 36—38. xxii. 16. The design of this institution, which was to express faith in Christ on the part of those who are baptized, and to declare their resolution of openly professing his religion, and cultivating real and universal holiness, appears from Rom. vi. 3, 4. 1 Peter, iii. 21. Ephes. v. 26. and Tit. iii. 5. Some have inferred from Acts, ii. 38. xxii. 16. Tit. iii. 4—7. that God did thereby give to believers a token of the forgiveness of their sins, according to the terms of the gospel covenant; and they have alleged, that there is a sense in which baptism may be called a seal of the covenant of grace.

We find no account of baptism as a distinct religious rite, before the mission of John, the forerunner of Christ, who was called the "Baptist," on account of his being commanded by God to baptize with water all who should hearken to his invitation to repent. Washing, however, accompanied many of the Jewish rites, and, indeed, was required after contracting any kind of uncleanness. Also, soon after the time of our Saviour, we find it to have been the custom of the Jews solemnly to baptize, as well as to circumcise, all their proselytes. As their writers treat largely of the reasons for this rite, and give no hint of its being a novel institution, it is probable, that this had always been the custom antecedent to the time of Moses, whose account of the right of circumcision, and of the manner of performing it, is by no means circumstantial. Or, baptism, after circumcising, might have come into use gradually from the natural propriety of the thing, and its easy conformity to other Jewish customs. For if no Jew could approach the tabernacle, or temple, after the most trifling uncleanness, without bathing, much less would it be thought proper to admit a proselyte from a state so impure and unclean as heathenism was conceived to be, without the same mode of purification. On the other hand, it has been alleged, that none of the washings which were practised among the Jews, bear the least resemblance to Christian baptism, except in the single circumstance of dipping; and this circumstance is a mere accident, and may as well be taken from Pagan rituals, as from the ceremonies of the Jews; or, in other words, it is so vague and far-fetched, that it deserves, in this point of view, no consideration at all. Accordingly,

it is maintained, there was no baptism in the world among any people till John, and that the purification of a proselyte by dipping himself, which is called baptism, was a late tradition, long after the time of John. The antiquity of this practice of proselyte-baptism among the Jews, has been a subject of considerable debate. It has been strenuously maintained by Lightfoot (*Works*, vol. ii. p. 120, &c.), Emlin (*Previous Question in Tracts*, vol. i. p. 394.), Wall (*History of Infant Baptism*, *Introd.*); and contended by Dr. Benfon (*On St. Paul's Epist.* vol. i. Disc. viii. p. ii.), Gale (*Reflections on Wall*), Robinson (*Hist. of Baptism*, p. 57.) &c. Dr. Benfon was at first an advocate for the Jewish custom of initiating heathen proselytes by baptism; but upon further inquiry he relinquished this opinion: alleging that he had not found any instance of one person's washing another by way of consecration, purification, or sanctification; except that of Moses's washing Aaron and his sons, when he set them apart to the office of priests, Lev. viii. 6.; and that he cannot find that the Jews do at present practise any such thing as that of baptizing the proselytes that go over to them, though they are said to make them wash themselves. He then asks, where is any intimation of such a practice among the Jews, before the coming of our Lord? If any one, he says, could produce any clear testimony of that kind from the Old Testament, the Apocrypha, Josephus, or Philo, that would be of great moment. He adds, in former times, proselytes coming over from heathenism to the Jewish religion, used to wash themselves, which is a very different thing from baptism, or one person's being washed by another. The genuine Targums, say Gill and Gals, written about the close of the first century, and the Mishna, written about the middle of the second century, say nothing on this subject. The Christian writers, called Fathers, speak of Jewish proselytes, and washings, and purifications from ceremonial uncleanness; but nothing of admitting proselytes into the community by baptism. The baptism of proselytes, it is said, came to light through the later Rabbies, and is chiefly to be sought in the writings of Maimonides, who flourished in the eleventh or twelfth century. In the Old Testament there are many precedents of admitting proselytes into the Jewish church, as Rahab, Ruth, and others; but not one word is said of their being baptized. Among the laws of admission given by Moses, Exod. xii. 48, 49, this is not mentioned. Dr. John Owen (*Theologoumena*) considers the opinion, that Christian baptism came from the Jews, as destitute of all probability. On the other hand, Mr. Wall has made it highly probable, to say the least, from many testimonies of the Jewish writers, who without one dissenting voice allow the fact, that the practice of Jewish baptism obtained before and at, as well as after, our Saviour's time. There is also a strong intimation, even in the gospel itself, of such a known practice among the Jews in the time of John the Baptist. John. i. 25. The testimonies of the Jewish writers are of the greater weight, because the practice, reported by them to have been of so ancient a date, did still remain among them; for if it had not been of that antiquity to which it pretends, viz. before the time of Christ, it is not likely that it would ever have become a custom among the Jews afterwards. Would they begin to proselyte persons to their religion by baptism in imitation of the disciples of Jesus of Nazareth, whom they held accursed? And yet if this proselyte baptism were adopted by the Jews since the time of Christ, it must have been a mere innovation in imitation of Christians, which is not very likely. See on this subject Maimon. in *Mishna*. tom. ii. *Isure bia*. c. 1. and c. 13. Selden de *Jure Naturali*, &c. l. ii. c. 2. Altingius de *Proselytis*, diff. 7. § 46. Vi-

tring. Archifynagog. c. 18. Curcellæi Inſtit. l. v. c. 2. § 7. Ainfworth on Gen. xxii. 12. Lightfoot ad Matt. iii. 6. The queſtion of the Pharifees to John the Baptiſt, "Why baptizeſt thou?" evidently favours the ſuppoſition, that ſuch a cuſtom exiſted; and our Saviour's queſtion to Nicodemus, "Art thou a maſter, or teacher, in Iſrael, and knoweſt not theſe things?" is a manifeſt alluſion to the cuſtom of initiating proſelytes by water-waſhing or baptizing, who after being ſo waſhed or baptized, were eſteemed regenerated or born again; and therefore to a ruler in Iſrael, who could not be unacquainted with theſe things, our Saviour's diſcourſe ought not to have appeared ſo unintelligible. Origen, in his Com. on Epil. to the Romans, c. 6. ſays, that Chriſt was baptized by John, not with that baptiſm which is in Chriſt, but with that which is in the law; implying, that under the law there was ſuch a cuſtom of baptizing. See alſo Arrian in Epiſt. l. ii. c. 9.

In the primitive times, this ceremony was performed by immerſion, as it is to this day in the oriental churches, according to the original ſignification of the word. However, it is not improbable, that when great numbers were baptized at the ſame time, the water was applied by ſprinkling, which was a practice ſufficiently familiar to the Jews. The practice of the weſtern churches is, to ſprinkle the water on the head or face of the perſon to be baptized, except in the church of Milan, in whoſe ritual, it is ordered, that the head of the infant be plunged three times into the water; the miniſter at the ſame time pronouncing the words "*I baptize thee in the name of the Father, the Son, and the Holy Ghoſt*;" importing that by this ceremony the perſon baptized is received among the profeſſors of that religion, which God, the Father of all, revealed to mankind by the miniſtry of his Son, and confirmed by the miracles of his Spirit.

It is observable that the baptiſmal form, above cited from St. Matthew, never occurs in the ſame words, either in the book of the Acts, or in any of the Epistles. But perſons are required to be baptized in the name of Chriſt, or ſaid to have been baptized into Chriſt; that is, they made a profeſſion of faith in Jeſus, as the Chriſt, and acknowledged their obligations to him, by being baptized. Acts, ii. 38. viii. 16. 35. 38. Rom. vi. 3. Gal. iii. 27. But though the form which is in St. Matthew never appears elſewhere, the thing intended thereby is always implied. Nor could any be brought to make a profeſſion of faith in Jeſus, as the Chriſt, but upon the ſuppoſition that he had taught in the name and with the authority of God the father, and had proved his commiſſion by miraculous attellations which could not be denied nor gainſaid. It is obſerved that the baptiſm of Jeſus was, like that of John, a reception to his inſtruction, or information in his doctrine, or concerning him; as appears from his own injunction, Matt. xviii. 19, 20; and alſo from that clauſe which has been conſidered as the form of Chriſtian baptiſm; which ought to have been rendered not *in*, but (*us*) *unto, into, or upon*, the name of God, of Chriſt, and of the Holy Spirit. The verſion which ſome have preferred is, "baptize *upon* the name of the Father, and of the Son, and of the Holy Spirit;" i. e. receive them to inſtruction upon theſe ſubjects; thus expreſſing what were to be the topics of their information, and what the great and diſtinguiſhing character of the inſtitution. On the part of the baptizer, baptiſm was a form of reception to inſtruction; and on the part of the perſons coming to baptiſm, it was an acknowledgment of the truth of the pretenſions of the perſon who baptized, an acknowledgment of his capacity and of his authority to propoſe himſelf as a religious inſtructor, and a deſire of being initiated into his ſchool, for the purpoſe of conforming to his diſcipline.

Hence it would follow, that "to be baptized *unto, or upon* Chriſt," was a public ſolemn profeſſion of faith in him. However the baptiſm of the Ethioſian miniſter by Philip, in a ſcene ſo private, and before ſo few, if indeed before any witneſſes, ſeems to be inconſiſtent with the notion that baptiſm was a ſolemn public profeſſion of faith in Chriſt; and the requiſition of a previous verbal declaration of ſuch faith totally overturns it. See Cappe's Diſſertation on Baptiſm, in Crit. Rem. vol. ii. p. 102.

Baptiſm is not to be repeated, ſince it is a right of initiation into Chriſt's church. However, thoſe perſons might be baptized in the name of Jeſus, as the Meſſiah already come, who had before been baptized by John and his diſciples into the general expectation of a Meſſiah ſhortly to be revealed. Compare Acts, xix. 5. The Chriſtians in Abyſſinia repeat their baptiſm annually, on the feſtival of Epiphany. The naming of the baptized perſon is by no means any part of this inſtitution; and when it is uſed, is to be conſidered as an addreſs to the perſon, calling him by his name, rather than as the manner of giving a name to him; though it is probable, that the cuſtom of naming a child at baptiſm might ariſe from the practice of the Jews at their circumciſion. Luke, i. 59-63. ii. 21.

A triple immerſion was at an early period uſed, and continued for a long time: this was to ſignify either the three days that our Saviour lay in the grave, or the three perſons in the Trinity. But it was afterwards laid aſide, becauſe the Arians uſed it; it was then thought proper to plunge but once. (See IMMERSION.) Some are of opinion that ſprinkling in baptiſm was begun in cold countries. It was introduced into England about the beginning of the ninth century. At the council of Celchyth, in 816, it was ordered, that the prieſt ſhould not only ſprinkle the holy water upon the head of the infant, but likewiſe plunge it in the baſon. Some have referred the introduction of ſprinkling in the church of Rome to a canon of pope Stephen III., who, during his reſidence in France, in 754, was conſulted by ſome monks of Creſſy in Britanny with regard to ſeveral queſtions; one of which is ſaid to have given occaſion to the firſt authentic law for adminiſtering baptiſm by pouring, which in time was interpreted to ſignify ſprinkling. The queſtion propoſed was, whether in caſe of neceſſity occaſioned by illneſs of an infant, it were lawful to baptize by pouring water out of the hand or a cup on the head of the infant? To which Stephen replied, that if ſuch a baptiſm were performed in ſuch a caſe of neceſſity, in the name of the holy Trinity, it ſhould be held valid. This, ſays the learned James Baſnage (Monum. vol. i. præf. c. v. §. 4. de Canone Steph. III. Papæ), is accounted the firſt law for ſprinkling, but it doth not forbid dipping; allowing it only in caſe of imminent danger. He adds, that the authenticity of it is denied by ſome Catholics; that many laws were made after this time in Germany, France, and England, to compel dipping, and without any provision for caſes of neceſſity; and therefore that this law did not alter the mode of dipping in public baptiſms, and that it was not till 557 years after, that the legiſlature, in a council at Ravenna, in the year 1311, declared dipping or ſprinkling indifferant. It has been alleged, that this answer of Stephen is the true origin of private baptiſm and of ſprinkling. The introduction of ſprinkling inſtead of dipping, in ordinary caſes, into this iſland, is ſaid to have been effected by ſuch Engliſh, or more ſtrictly ſpeaking Scots exiles, as were diſciples of Calvin at Geneva, during the Marian perſecution; and it is added, that the Scots Calviniſts, who firſt introduced ſprinkling in ordinary baptiſm into the northern parts of the iſland, were the importers of it into the ſouthern. In the

reign of king Edward, the established church practised in ordinary cases true immersion; and pouring or sprinkling was allowed, only in cases of danger, in private. It is further argued by those who maintain that in the primitive church there is no mention of baptizing by pouring, that the administration of baptism by sprinkling was first invented in Africa in the third century, in favour of clinics, or bed-ridden people; but that even African Catholics, the least enlightened and the most depraved of all Catholics, derided it, and reputed it no baptism. See Jo. Andreæ Bosii de Clinicis exercit. Hist. Janæ, cited by Robinson in his "History of Baptism," p. 449. In the liturgy of the English church at Frankfort, king Edward's service book was used, and baptism was administered by true immersion. In the Scots church at Geneva, the minister was directed to take water in his hand, and lay it upon the child's forehead, which was called pouring. About 100 years after, in the assembly of divines, Dr. Lightfoot caused dipping to be excluded, and sprinkling declared sufficient. In the Eastern and Greek churches, dipping is said to have been the invariable mode of administering baptism from the first introduction of it to this day. See Dr. King's Rites of the Greek church.

There are many ceremonies delivered by ecclesiastical writers, as used in baptism, which were introduced after the age of Justin Martyr, but which are now disused; as the giving milk and honey to the baptized, in the East; wine and milk in the West, &c. They also added unction and the imposition of hands. Tertullian is the first who mentions the signing with the sign of the cross, but only as used in private, and not in public worship; and he particularly describes the custom of baptizing without mentioning it. Indeed, it does not appear to have been used in baptism till the latter end of the fourth or fifth century; at which time great virtue was ascribed to it. Lactantius, who lived in the beginning of the fourth century, says (Inst. l. iv. c. 27. p. 439.), the devil cannot approach those who have the heavenly mark of the cross upon them, as an impregnable fortress to defend them; but he does not say it was used in baptism. After the council of Nice, Christians added to baptism the ceremonies of exorcism and adjurations, to make evil spirits depart from the persons to be baptized. They made several signings with the cross, they used to light candles, they gave salt to the baptized person to taste, and the priest touched his mouth and ears with spittle, and also blew and spat upon his face. At that time also baptized persons wore white garments till the Sunday following. They had also various other ceremonies; some of which are now abolished, though others of them remain in the church of Rome to this day.

The Quakers (see QUAKERS) assert, that water baptism was never intended to continue in the church of Christ any longer than while Jewish prejudices made such an external ceremony necessary; which they argue from that passage, in which *one* baptism is spoken of as necessary to Christians; Ephes. iv. 5. which, as they say, must be a baptism of the spirit. But from comparing the texts that relate to this institution, which have been already cited, it will plainly appear that water baptism was instituted by Christ in more general terms than will agree with this explication. That it was administered to all the Gentile converts, and not confined to the Jews, appears from Matt. xxviii. 19, 20. compared with Acts, x. 47; and that the baptism of the spirit did not supersede water baptism, appears to have been the judgment of Peter and of those that were with him; so that the one baptism spoken of seems to have been that of water; the communication of the Holy Spirit being

only called baptism in a figurative sense. As for any objection which could be drawn from 1 Cor. i. 17. it is sufficiently answered by the preceding verses, and all the numerous texts, in which, in epistles written long after this, the apostle speaks of *all* Christians as baptized; and argues from the obligation of baptism, in such a manner as we can never imagine he would have done, if he had apprehended it to have been the will of God that it should be discontinued in the church. Compare Rom. vi. 3, &c. Col. ii. 12. Gal. iii. 27.

Baptism was also wholly rejected by the Valentinians, Manichees, Paulicians, and many other sects.

Several of the Socinians have maintained, that baptism was only to be used by those who are converted to Christianity from a different profession; and that though the children of such proselytes were to be baptized with their parents, all who descended from them were to be considered as baptized in them; and they were the practice of proselyte baptism among the Jews in support of this opinion. (See Emlyn's Previous Question, ubi supra). However, it has been alleged in reply, that the antiquity of this practice of proselyte baptism among the Jews has been doubted, and even disallowed by many; and if it be admitted, all the rules and circumstances relating to it might not be known even to the apostles themselves; and it is also probable, that some of the rules of proselyte baptism did not prevail among them so early, particularly that which supposed that all natural relations were annulled by it. Besides, although it be acknowledged that no instance occurs in the earliest primitive antiquity, in which the baptism of any child of Christian parents, whether infant or adult, is expressly mentioned; yet it is certain that Christians in general have always been spoken of by the most ancient fathers as baptized persons; and the apostles, when writing to Christian churches planted many years before the date of their respective epistles, argue with the members of them from the obligation which their baptism brought upon them, in such a manner as would lead us to conclude, that they were baptized in their own persons; and it is also certain, that as far as our knowledge of primitive antiquity reaches, no unbaptized person received the Lord's supper, which, nevertheless, was an ordinance none will deny that the descendants of Christians participated. It is added, that on this supposition, genealogies would be of great importance in religion, contrary to what St. Paul intimates; nor can it be reasonably thought that our right to Christian communion should rest on a fact, the evidence of which might sometimes be so obscure, as the baptism of some remote ancestor. See Gale's Serm. vol. ii. N^o 9. Benson on 2 Tim. p. 134—136. Whit. Life, vol. i. p. 367, 368.

Theological authors distinguish three kinds of baptism: 1. Water baptism, which is that above-mentioned. 2. Baptism of fire, which is the perfect love of God, joined with an earnest desire to be baptized; called also the *baptism of the Holy Ghost*: on occasion this may supply the place of water baptism. 3. Baptism of blood, which is the martyrdom of a catechumen.

Baptism, in the primitive times, was only administered at Easter and Whitsuntide, except in cases of necessity. Adult persons were prepared for baptism by abstinence, prayer, and other pious exercises. It was to answer for them, says Moheim (Eecl. Hist. vol. i. p. 211.), that sponsors, or godfathers, were first instituted in the second century, though they were afterwards admitted also in the baptism of infants. This, according to M. Daillé, was not done till the fourth century. Wall (Hist. Inf. Bapt. vol. i. p. 49.) refers the origin of sponsors, or godfathers, on the authority

authority of Tertullian, to the commencement of the second century; who were used in the baptism of infants that could not answer for themselves. (See GODFATHERS.) The catechumens were not forward in coming to baptism: St. Ambrose was not baptized before he was elected bishop of Milan; and some of the fathers not till the time of their death. Some deferred it out of a tender conscience; and others out of too much attachment to the world; it being the prevailing opinion of the primitive times, that baptism, whenever conferred, washed away all antecedent stains and sins. Accordingly they deferred this sanctifying rite as long as possible, even till they apprehended they were at the point of death. Cases of this kind occur at the beginning of the third century. Constantine the Great was not baptized till he was at the last gasp, and in this he was followed by his son Constantius; and two of his other sons, Constantine and Constans, were killed before they were baptized. Divers of the fathers rallied this superstitious delicacy to such a degree, that they introduced a different extreme; the ridiculous zeal of some people carrying them to baptize even the dead, by proxy. Epiphanius, Chrysostom, and Theodoret, observe, that this custom prevailed in some places in their time. See Basnage Hist. des Eglises Reformées, vol. i. p. 137.

The opinion of the necessity of baptism in order to salvation, is grounded on these two sayings of our Saviour: "He that believeth, and is baptized, shall be saved;" and, "Except a man be born of water, and of the spirit, he cannot enter into the kingdom of God." Mark xvi. 16. John iii. 5. In the age immediately following that of the apostles, we find that baptism and regeneration were used as synonymous terms; and whereas, originally, the pardon of sin was supposed to be the consequence of that reformation of life which was only promised at baptism, it was now imagined that there was something in the rite itself, to which that grace was annexed; and in general it seems to have been imagined that this sanctifying virtue was in the water, and in no other part of the ordinance as administered by the priest. Tertullian says, that the Holy Spirit was always given in baptism; and he says, that the spirit of God descends upon the water of baptism like a dove. Chrysostom asserts, that the water ceases to be what it was before, and is not fit for drinking, but is proper for sanctifying; and that the Christian baptism is superior to that of John, as his was the baptism of repentance, but had not the power of forgiving sin. Austin says, that it touches the body, and purifies the heart. Basnage (*ubi supra*), p. 138. And it appears by a passage in Austin, that the African Christians usually called baptism *salvation*, and the eucharist *life*, preferring the former to the latter. Wickliff thought baptism to be necessary to salvation. "The priest," he says, "in baptism administers only the token or sign, but God, who is the priest and bishop of our souls, administers the spiritual grace." Gilpin's Life of Wickl. p. 64. It is also the language of the public forms of the church of England, that baptism is necessary to salvation, and that by baptism an infant is regenerated, becomes a child of God by adoption, and is incorporated into God's holy church. Similar to this is the doctrine of the church of Scotland; for, in their confession of faith, baptism is said to be a sign or seal of the covenant of grace, of persons ingrafting into Christ, of regeneration, of remission of sins, &c. As to the necessity of baptism, we may observe, however, that, though some seem to have laid too great stress upon it, as if it were indispensably necessary in order to salvation; it must be allowed, that for any person to omit baptism, when he acknowledges it to be an institution of Christ, and that it is the

will of Christ that he should submit to it, is an act of disobedience to his authority, which is inconsistent with true faith.

Mr. Dodwell maintains that the ordinance of baptism, if administered by persons duly ordained, conveys an immortalizing spirit; whereas persons dying unbaptized are not immortal. Mr. Hallet also (*Notes on Script.* vol. iii. p. 299—311.), though he does not assert it in express terms, seems to intimate something very like it, when he says, that circumcision was that which gave the infant a right to immortality; and that baptism in this respect comes in the room of circumcision; and yet that no infants are miserable in a future state.

Some have maintained that the commission to baptize was addressed by Jesus only to the apostles; and hence they argue that none but apostles and apostolical men, their successors, have any right to administer baptism. But it has been asked by others, is it a true fact that during the lives of the apostles, none but they baptized? Philip the deacon baptized the Samaritans (Acts xviii. 5—14); there was no apostle at Damascus when Paul was baptized, but he was baptized by a certain disciple named Ananias. Acts ix. 18. Rom. vi. 4. See also Acts xviii. 2, &c. Acts x. 5—23. It is also inquired further by persons of this latter class, who are the successors of the apostles? and whether or not Jesus instituted a priesthood or any order of men to succeed the apostles? It is, however, a fact which cannot be contested, that in the earliest age of the Christian church, the bishop only, or the priests by his permission, administered baptism; as, with his leave, they also performed any other of his functions: but it appears from Tertullian, that in his time laymen had in some cases the power of baptizing. This baptism, nevertheless, seemed to have required the confirmation of the bishop, and would not be allowed but in case of necessity, as at the approach of death, &c. At a synod at Elvira, in 306, it was allowed, that a layman, provided he had not been married a second time, might baptize catechumens in case of necessity; but it was ordered, that if they survived they should be brought to the bishop for the imposition of hands. Afterwards, when the bounds of the church were much enlarged, the business of baptism was left almost entirely to the priests, or the country bishops; and the bishops of great sees only confirmed afterwards. It seems, however, to be decent and proper, that baptism should be administered only by the teachers and ministers of the church, where their assistance can be had; not only because it appears that these were the persons by whom it was administered in the New Testament, but because, *ceteris paribus*, they must be most capable of judging who are the fit subjects of it.

Great doubts were raised in early times about the validity of baptism as administered by heretics. Tertullian, before he became a Montanist, wrote a treatise to prove that heretics, not having the same God or the same Christ with the orthodox, their baptism was not valid. Cyprian called a synod at Carthage, in which it was determined, that no baptism was valid out of the Catholic church, and therefore, that those who had been heretics should be re-baptized. But Stephen, the bishop of Rome, did not approve of this decision; and by degrees his opinion, which continued to be that of the church of Rome, became every where prevalent. Indeed, when so much stress was laid upon baptism itself, it would have introduced endless anxiety, if much doubt had remained about the power of administering it. For a further account of the subjects and mode of baptism, see BAPTISTS, and PÆDOBAPTISTS; see also ANA-BAPTISTS.

BAPTISM of the Dead, a custom which anciently prevailed

vailed among some people in Africa. The third council of Carthage speaks of it as a thing that ignorant Christians were fond of. Gregory Nazianzen also takes notice of the same superstitious opinion prevailing among some who delayed to be baptized. In his address to this kind of men, he asks, whether they staid to be baptized after death? Philastrius also notes it as the general error of the Montanists or Cataphrygians, that they baptized men after death.

The practice seems to be grounded on a vain opinion, that when men had neglected to receive baptism in their life-time, some compensation might be made for this default by receiving it after death.

BAPTISM *of the Dead* was also a sort of vicarious baptism formerly in use, where a person dying without baptism, another was baptized in his stead; a practice founded on 1 Cor. xv. 29. concerning the feast of which passage critics have been much divided. Several Catholics understand it of the baptism of tears, penance, and prayers, which the living undergo for the dead, and allege it as a proof of the belief of purgatory in the apostles' days. See Heinius's Exerc. ad Nov. Test. lib. vii. cap. 13.

Michaelis understands, with Grotius and Simon, by βαπτισμος ὑπὲρ νεκρῶν, or baptism for the dead, a vicarious baptism for the dead. Whether this vicarious baptism was practised in the first century, and meant by the apostle, it is difficult at present to determine; and Dr. Teller, one of the most sensible expositors of the New Testament, candidly confesses, that he is unable to comprehend the meaning of the passage. It is, however, certain that the custom was not unknown in the fourth century, as appears from Chrysostom's 40th homily to the first epistle to the Corinthians; and in the same century it was not unusual to defer baptism till the approach of death, and if the patient died suddenly, to baptize even the deceased. Michaelis's Introd. by Marsh, vol. i. p. 359.

Others have supposed that the superstitious custom of baptizing a living person as the representative of one who had died unbaptized, is more likely to have arisen from an erroneous interpretation of this passage than to have been so early prevalent. Some conceive that νεκρῶν is here put for νεκρῶν, and refers to those who were baptized into the religion of Jesus, who on the hypothesis of the adversaries against whom the apostle reasons, is *still dead*. Sir Richard Ellys, in his "Fortuita Sacra," p. 137. interprets these words in the following manner: "what should they do who are baptized, in token of their embracing the Christian faith, in the room of the dead, who are just fallen in the cause of Christ, but are yet supported by a succession of new converts, who immediately offer themselves to fill up their place, as ranks of soldiers that advance to the combat in the room of their companions, who have just been slain in their fight". Doddr. in loc. Wakefield (Translation, vol. ii. p. 89.) renders the words: "Besides, what advantage above the *other* dead will they have, who are submitting constantly to baptism? Why indeed are they *this* baptized, if the dead will certainly live no more? Why should we too expose ourselves to the danger of it *every* hour?" The apostle, says this critic, here begins a new argument of the resurrection, grounded on the practice of the apostles themselves, who had been eye-witnesses of their matter's revival. What contributed not a little to obscure this passage, he adds, was the second ὑπὲρ τῶν νεκρῶν, a clause not acknowledged by the Coptic and Ethiopic versions. For this sense of baptism, the reader may consult Matt. xx. 22. Luke xii. 50. Euseb. Eccl. Hist. vi. 4. fin.; and for an illustration of the argument, Rev. xx. 4.

BAPTISM, *Lay*, seems to have been allowed in the rubric

of the English liturgy, till the time of king James I. though there were great disputes among the bishops at the Hampton-court conference in 1623, whether the words of the liturgy imported such allowance or not. The bishop of Worcester allowed them to be doubtful; but that the contrary practice of the church, which censured women for conferring baptism, shewed, that the compilers of the book did not intend them as a permission: they had indeed propounded them ambiguously, because otherwise, perhaps, the book would not have passed the parliament. The archbishop of Canterbury insisted, that the administration of private baptism by women and laymen was not allowed in the practice of the church, but, on the contrary, censured by the bishops in their visitations. He even added, that the words of the liturgy do not infer any such meaning. To which king James excepted; urging and pressing the words of the book, that they could not but intend a permission of women and private persons to baptize. Till this time it had been customary for bishops to license midwives to their office, and to allow their right to baptize in cases of necessity, under an oath which was prescribed to them.

At present, the English divines condemn it as invalid; and Burnet, bishop of Sarum, was severely handled by some of them, for asserting that faith in the Trinity gives every man a right to baptize. Collins's Disc. on Free-Think. p. 73.

BAPTISM, *Clinic*. See CLINIC.

BAPTISM is also applied abusively to certain ceremonies used in giving names to many inanimate things.

BAPTISM, in *Sea Language*, is a ceremony in long voyages aboard merchant-ships; practised both on persons and vessels which pass the tropic, or equinoctial line, for the first time.

That of vessels is simple, and consists only in the washing them throughout with sea-water; that of passengers is ludicrous: but neither the one nor the other is done without making the crew drunk; the seamen, on christening the ship, pretending to a right of cutting off the break-head, unless redeemed by the master or captain.

BAPTISM of Bells. See BELL.

BAPTISMAL FONT. See BAPTISTERY.

BAPTISMAL Presents are in use in Germany, made by the sponsors to the infant, consisting of money, plate, or even sometimes fields of lands; which, by the laws of the country, are to be kept for the child till of age, the parents having only the trust, not the right of disposing of them.

An anonymous author has published a discourse express on this occasion, intitled, "De Pecunia Lutrica."

BAPTISMAL Vow, or Covenant, a profession of obedience to the laws of Christ, which persons, in the ancient church, made before baptism.

It was made by turning to the East, but for what mystical reasons is not well agreed.

BAPTIST, JOHN MONNOYER, in *Biography*, an eminent painter of flowers and fruit, was born at Lille in 1635, and educated at Antwerp. The composition and colouring of this master are in a bolder style than those of Van Huysum, but his pictures are not so exquisitely finished. The disposition of his objects is so elegant and beautiful as to form a test by which his compositions may be distinguished from those of other masters. He was invited to England by the duke of Montagu, and employed in conjunction with La Fosse and Rouleau, to embellish Montague house, which is now the British Museum, and in which are preserved some of the finest performances of Baptist. A very celebrated work of this artist is a looking-glass preserved in the royal palace at Kennington, decorated with a garland

garland of flowers, for queen Mary II. who sat by him during the greatest part of the time whilst he was employed in painting it. He died in 1699. His son Anthony Baptist was also a painter of flowers in the style and manner of his father. Pilkington.

BAPTIST, JOHN, GASPARS, a painter of history and portrait, was born at Antwerp, and was a disciple of Thomas Willeborts Boschaert. During the civil wars he came over to England; and after the restoration was employed by sir Peter Lely, to paint the postures and draperies of his portraits, and distinguished by the name of Lely's Baptist. He made designs for tapestry, which were accounted good, and his drawing was generally correct. In the hall of St. Bartholomew's hospital there is a portrait of king Charles II. painted by this master. He died in 1691. Pilkington.

BAPTISTERY, in *Ecclesiastical Writers*, a place or edifice where water is preserved for persons to be baptized in. Anciently, in the churches which baptized by immersion, the baptistery was a kind of pond where the catechumens were plunged; though in many places the next river served for a baptistery, which was the case in the time of Justin Martyr and of Tertullian.

About the middle of the third century, they began to build baptisteries; but there were none that adjoined to churches till the year 496, and then they stood without the church, and of this kind the first was prepared for the baptism of Clovis king of France, who, with his sister Audofledis, was dipped three times by immersion. But there were none within the churches till the sixth century; and it is remarkable, that though there were many churches in one city, yet, with few exceptions, there was but one baptistery. This simple circumstance became in time a title to dominion; and the congregation nearest the baptistery, and to whom in some places it belonged, and by whom it was lent to the other churches, pretended that all the others ought to consider themselves as dependent upon them. When the fashion of dedication was introduced, the church that owned the baptistery was generally dedicated to St. John the Baptist, and assumed the title of St. John *in fonte*, or St. John *ad fontes*, that is, the church near or at the baptistery. The noble and splendid cities of Florence, Pisa, Bologna, Parma, Milan, and many others in Italy, had but one baptistery in each; and these baptismal churches were usually built near rivers and waters, as was the case with respect to those of Milan, Naples, Ravenna, Verona, and many more. In later times, the bishop of the baptismal church, having obtained secular power, granted licences for other churches to erect baptisteries; taking care at the same time to maintain his own dominion over the people.

By a baptistery, which must not be confounded with a modern font, is to be understood an octagon building, with a cupola roof, resembling the dome of a cathedral, adjacent to a church, but forming no part of it. The whole middle part of this edifice was one large hall capable of containing a great number of people; the sides were parted off, and divided into rooms; and in some, rooms were added on the outside in the fashion of cloisters. In the middle of the great hall was an octagon bath, which, strictly speaking, was the baptistery, and from which the whole building derived its appellation. Some of these were erected over natural rivulets; others were supplied by pipes, and the water was conveyed into one or more of the side-rooms. Some of the surrounding rooms were vestries, others school-rooms, both for transacting the affairs of the church, and for the instruction of youth. They were large and capacious; for as baptism was administered only twice a year, the candidates were numerous, and the spectators more numerous

than they. In process of time there were baptisteries at most of the principal churches of Rome, as at those of St. Peter, St. Laurence, St. Agnes, St. Pancras, and others. The most ancient is that at St. John Lateran. Baptisteries were also erected separate from the churches in all the principal cities of Italy, as Florence, Ravenna, Milan, Pisa, Parma, and the rest. The baptistery annexed to the spacious and splendid church of St. Sophia at Constantinople, resembled the convocation room of a cathedral; it was very large; councils have been held in it; and it was called *μυστὸς καταβύτιον*, the great illuminatory. In the middle was the bath, in which baptism was administered; and there were outer rooms for all concerned in the baptism of immersion, the only baptism of the place. The Lateran baptistery at Rome, belonging to the church of St. John Lateran, is an octagon edifice, the roof of which is supported by eight large polygonal pillars of porphyry; and under the cupola, in the centre of the floor, is the baptistery properly so called, lined with marble, with three steps for descent into it, and about five Roman palms, or 57½ inches, deep. Ciampini apprehends, after much investigation of the opinion of antiquarians, that this baptistery was originally a bath in the precincts of the imperial palace; that it was begun to be converted into a baptistery by the emperor Constantine; that the buildings were carried on by pope Xystus III.; and that they were completed and ornamented by pope Hilary. Baptisteries were in fashion in Italy from the reign of Constantine to that of Charlemagne, during a period of about 500 years; and within this interval they were amply adorned and endowed. The first gifts of the faithful were milk, honey, and wine, for the refreshment of the catechumens and their attendants; the next were oils, unguents, and salts; along with these came cups, vases, plates, and utensils, marked with the initial letters of the name of John Baptist, I. B. or John the fore-runner, *IOAN IPOΔ*, which perhaps is the true origin of baptismal inscriptions; then came money for the poor, and for the support of those who spent their time in teaching and officiating; after these came habits, ornaments, pictures of John holding out his right hand, with a lamb lying in it, being a reference to his words, "Behold the lamb of God;" and these were followed by others more complex; the whole forming a large body of superstitious theology, glaring in practice, but cumbersome to virtue.

In the baptism of infants, it was unnecessary for the administrators to go into the water, and therefore they contrived cisterns, which they called *fontes*, in which the children were dipped. These were at first small baths, erected on a platform, into which those who performed the ceremony plunged children, without going into the water themselves. In modern practice, the font remains, but a basin of water set in the font serves the purpose, because it is not thought necessary either that the administrator should go into the water, or that the candidate should be immersed. This in England was custom, but not law; for in the time of queen Elizabeth, the governors of the episcopal church did in effect expressly prohibit sprinkling, by forbidding the use of basins in public baptism. See "A booke of certaine canons, concerning some parte of the discipline of the church of England," in 1571, by John Daye, p. 19. Fonts in parish-churches for the purpose of baptizing infants were introduced soon after the arrival of Aulin the monk; and each parish was enjoined to provide fonts of wood and stone for this purpose. In the old church of St. Peter at Oxford, built by Gymbald, who was brought over from Flanders into England by Alfred, in the year 885, there was till lately a very ancient baptismal font, of a circular form, and elegant sculpture,

eleven feet in circumference, and of proportionable depth, with the twelve apostles represented in separate niches. After having kept its place about 500 years, it was ordered to be removed, and another much inferior put in its place. In the church of Bridekirk, near Cockermouth in Cumberland, there is a large open vessel of greenish stone, which antiquaries pronounce to be a Danish font. The chief characters on this baptismal font (see Gibson's Camden's Brit. vol. ii. p. 1007.) are Runic, but some are purely Saxon. This is supposed to be the oldest font yet remaining in this kingdom, being of the ninth century, when the Danes first received the Catholic religion. Whether the font be Danish or Saxon, the baptism which it exhibits is that of the Catholics opposed to that of the old Pelagian Britons.

There were several fonts and altars in each baptistery, because then they baptized at once, all of whom received the eucharist immediately after.

The right of having fonts was confined to parishes alone; and if any monasteries were found with baptismal fonts, it was because they had baptismal churches in another place: though the bishops sometimes granted them to monks, upon condition that they would have a secular priest along with them to take care of the people; but they afterwards found means to throw off the priest, and make themselves masters of the church, and attach it, with its baptismal fonts, to their own monastery. For a copious account of baptisteries and fonts, illustrated by figures, see Robertson's History of Baptism, p. 56—131.

BAPTISTERY is also used for a baptismal or parochial church.

BAPTISTERY is also used, by the *Armenians*, for the feast of Epiphany, when the anniversary of Christ's baptism is celebrated.

BAPTISTERY is also used for a church-book, wherein the prayers and ceremonies of baptism were particularly described. Some take the *baptisterium* to have contained the order of all the sacraments, except the eucharist.

BAPTISTS, in *Ecclesiastical History*, from *βαπτίζω*, *I baptize*, a denomination of Christians, distinguished from other Christians by their particular opinions respecting the mode and the subjects of baptism.

Instead of administering the ordinance by sprinkling or pouring water, they maintain that it ought to be administered only by immersion. Such, they insist, is the meaning of the word *βαπτίζω*; so that a command to baptize is a command to immerse. Thus it was understood by those who first administered it. John the Baptist, and the apostles of Christ, administered it in Jordan and other rivers and places where there was much water. Both the administrators and the subjects are described as going down into, and coming up again out of the water. And the baptized are said to be buried in baptism, and to be raised again; which language could not, they say, be properly adopted on supposition of the ordinance's being administered in any other manner than by immersion. Thus also, they affirm, it was in general administered in the primitive church. Thus it is now administered in the Russian and Greek church; and thus it is, at this day, directed to be administered in the church of England, to all who are thought capable of submitting to it in this manner. With regard to the subjects of baptism, the baptists say, that this ordinance ought not to be administered to children or infants at all, nor to grown up persons in general, but to adults only of a certain character and description. Our Saviour's commission to his apostles, by which Christian baptism was instituted, is to go and teach all nations, baptizing them: that is, say they, not to baptize all they meet with; but first to instruct

them—to teach all nations, or to preach the gospel to every creature—and whoever receives it, him to baptize in the name of the Father, and of the Son, and of the Holy Ghost. To such persons, and to such only, baptism appears to have been administered by the apostles, and the immediate disciples of Christ. They are described as repenting of their sins, as believing in Christ, and as having gladly received the word. Without these qualifications, Peter acquaints those who were converted by his sermon, that he could not have admitted them to baptism. Philip holds the same language in his discourse with the eunuch. And Paul treats Lydia, the jailor, and others, in the same manner. Without these qualifications, Christians in general think it wrong to admit persons to the Lord's supper, and, for the same reasons, without these qualifications, at least a profession of them, the Baptists think it wrong to admit any to baptism. Wherefore they withhold it, not only from the impenitently vicious and profane, and from infidels who have no faith, but also from infants and children, who have no knowledge, and who are incapable of every action civil and religious. They farther insist, that all positive institutions depend entirely upon the will and declaration of the institutor; and that therefore reasoning by analogy from previous abrogated rites is to be rejected, and the express commands of Christ respecting the mode and subjects of baptism ought to be our only rule.

The Baptists in England form one of the three denominations of Protestant dissenters. They separate from the establishment for the same reasons as their brethren of the other denominations do, with whom they are united; and from additional motives derived from their particular tenets respecting baptism. The constitution of their churches, and their modes of worship, are congregational or independent: in the exercises of which they are protected, in common with other dissenters, by the act of toleration. Before this act, they were liable to pains and penalties as non-conformists, and often for their peculiar sentiments as baptists. A proclamation was issued out against them, and some of them were burnt in Smithfield in 1538. They bore a considerable share in the persecutions of the 17th and of the preceding centuries; and, as it should seem, in those of some centuries before; for there were several among the Lollards and the followers of Wickliff, who disapproved of infant baptism. There were many of this persuasion among the Protestants and reformers abroad. In Holland, Germany, and the North, they went by the names of ANA-BAPTISTS and MENNONITES; and in Piedmont and the South, they were found among the ALBIGENSES and WALBENSES. See the Histories of the Reformation, and the above articles in this Dictionary.

The Baptists subsist under two denominations, viz. the *Particular* or Calvinistical, and the *General* or Arminian. The former is by far the most numerous. Some of both denominations allow of mixed communion, others disallow it; and some of them observe the seventh day of the week as the sabbath, apprehending the law that enjoined it not to have been repealed by Christ or his apostles. But a difference of opinion respecting these and other matters is not peculiar to the Baptists; it is common to all Christians, and to all bodies of men who think and judge for themselves. See PÆDOBAPTISTS, under which article an account will be given of the principal arguments in favour of infant baptism.

BAR, in *Architecture*, a long slender piece of wood or iron, used to keep things close and fast together.

In this sense, we speak of bars of windows, of doors, and the like.

Bars of iron are made of the metal of the fows and pigs as they come from the furnaces.

These pass through two forges, called the finery and the chaufery; where, undergoing five several heats, they are formed into bars. Phil. Trans. N^o 138. p. 954. See **IRON**, and **FORGE**.

Bar Shot, in *Artillery*. See **SHOT**.

To Bar or strike a Vein, among *Farriers*, an operation performed on the veins of a horse's legs, or other parts of his body, in order to stop the course, and lessen the quantity of malignant humours prevailing there.

It is thus performed: the farrier opens the skin, after disengaging the vein, ties it above and below, and then strikes between the two ligatures.

Bar of a Port, in *Marine Fortification*. See **BOOM**.

Bar, in *Geography*, is used for a heap of sand or mud, or a chain of rocks, which block up the mouth of a river or port, so that there is no entrance except at high water. The bar of Siam is a remarkable bank of mud, gathered in the mouth of the river, which allows not above thirteen feet of water, when the tide is highest.

Bar, a town of Arabia, fifty-six miles south-east of El Catif, near the Persian gulph.

Bar, a town of Hindostan, in the country of Bahar, fifteen miles north of Bahar, and thirty E. S. E. of Patna.

Bar, Le, a town of France, in the department of the Var, and chief place of a canton in the district of Grasse, four miles north-east of Grasse.

Bar sur Aube, a town of France, and principal place of a district in the department of the Aube. N. lat. 48° 14'. E. long. 4° 36'.

Bar sur Seine, a town of France, and principal place of a district in the department of the Aube, situate at the foot of a mountain, on the Seine; it has three gates, a college, and an hospital; 5½ leagues S. E. of Troyes. N. lat. 48° 7'. E. long. 4° 16'.

Bar le Duc, a town of France, and principal town of a district in the department of the Meuse; and, before the revolution, the capital of the duchy of Bar. It is divided into the Upper and Lower town by a caille called the Bar, and was a kind of barrier between France and Lorraine. The walls and towers of this castle were demolished by Louis XIV. The river Ornain runs through the lower part of the town. It is seven leagues S. S. E. of St. Menchould, and 9½ west of Toul. N. lat. 48° 47'. E. long. 4° 4'.

Bar, Duchy of, was, before the revolution, the name of a country of France, situate to the west of Lorraine, thirty-two leagues long and sixteen wide; the face of the country is irregular, presenting hills and plains; and it abounds with wood, wine, corn, game, and fish. Its name was derived from the castle of Bar, and it was erected into a county by the emperor Otho, but the time when it was raised to a duchy is not ascertained.

Bar, a district of Switzerland, in the canton of Zug. See **ZUG**.

Bar, is also the name of a fortress of Poland, in Podolia.

Bar, in *Heraldry*, denotes an ordinary nearly resembling the *Fess*: it consists of two lines drawn horizontally across the field, and contains a fifth part thereof. The bar hath two diminutives; viz. a closet, which is in breadth one-half; and a barrulet, which is in breadth one-fourth of that of the bar. When the field is divided into four, six, eight, ten, twelve, or more equal parts, it is then blazoned, *barry*; and the number of pieces are to be specified, e. gr. *barry of so many pieces*; but if it contains an odd number, the field must be first named, and the number of bars expressed; they are then called bars. See **PLATE of Heraldry**.

Bars-Gemel, or **Bars-Gemelles**, are diminutives of the

bar, and are placed in pairs, or two and two on a shield. They derive their name from the Latin *gemelli*, twins. See **PLATE of Heraldry**.

Bar, in a *Court of Justice*, denotes an inclosure made with a strong partition of timber, three or four feet high, where the counsel are placed to plead causes; and where prisoners are brought to answer their indictments, &c.

This the French call *barre d'audience*, and in some places *auditoire*. It answers to what, among the Romans, was denominated *custodia*.

It is called bar, because inclosed with a barrier, called also in Latin writers *cancelli* and *caule*, by a metaphor taken from sheep-folds.

The denomination bar is also given to the benches where the lawyers or advocates are seated.—The appellation arose hence, that anciently there was a bar, or barrier, to separate the counsellors and pleaders from the attorneys and others.

Hence our lawyers who are called to the bar, or licensed to plead, in other countries called *licentiati*, are termed *bar-risters*. 24 Hen. VIII. c. 24.

Bar, or **BARR**, **BARRA**, in *Common Law*, denotes a peremptory exception against a demand or plaint.

The author of the "Terms de Ley" defines bar, a plea brought by the defendant in an action, whereby the action of the plaintiff is destroyed for ever. And it is divided into *bar* to common intentment, and *bar* special; the former is an ordinary or general bar, which is usually a bar to the declaration of the plaintiff; and the latter is that which occurs upon some special circumstance of the fact, as to the case in hand. Modern writers also divide bars into *perpetual* and *temporary*: bar perpetual, is that which overthrows the action for ever, and bar temporary, or bar *pro tempore*, is that which is allowed good for the present, but may fail, or be set aside hereafter. Plowd. 26. A plea in bar not giving a full answer to all the matter contained in the plaintiff's declaration, is not good. 1 Lill. Abr. 211. If one be barred by plea to the writ, or to the action of the writ, he may have the same writ again, or his right action again; but if the plea in bar be to the action itself, and the plaintiff be barred by judgment, &c. it is a bar for ever in personal actions. 6 Rep. 7. And a recovery in debt is a good bar to action on the case, for the same thing; also a recovery on assumpsit in case is a good bar in debt, &c. Cro. Jac. 110. 4 Rep. 94. In all actions personal, as debt, account, &c. a bar is perpetual, and in such case the party hath no remedy but by writ of error or attain; but if a man is barred in a real action or judgment, yet he may have an action of as high a nature, because it concerns his inheritance; as e. g. if he is barred in a *formedon in descender*, yet he may have a *formedon in the remainder*, &c. 6 Rep. 7. It has been resolved, that a bar in any action, real or personal, by judgment upon demurrer, verdict or confession, is a bar to that action, or any action of the like nature for ever; but, according to Pemberton, chief justice, this is to be understood, when it doth appear that the evidence in one action would maintain the other; for otherwise the court shall intend that the party hath mistaken his action. Skin. 57, 58.

Bar to a common intent is good; and if an executor be sued for his testator's debt, and he pleadeth that he had no goods in his hands at the day when the writ was taken out against him, this is a good bar to a common intentment, till it is shewn there are goods; but if the plaintiff can shew, by way of replication, that more goods have fallen into his hands since that time, then, except the defendant allege a better bar, he shall be condemned in the action. Plowd. 26. Kitch. 215. Bro. tit. *Barre*. See **PLEA**.

Bar of Dower. See **DOWER**.

BAR, *Trial at.* See TRIAL.

BAR, in the *Manege*, denotes the ridge or upper part of the gums, between the tusks and grinders of a horse; the under and outward sides retaining the name gums.

The bars should be sharp-ridged and lean; for since all the subjection a horse suffers, proceeds from those parts, if they have not these qualities, they will be very little, or not at all sensible; so that the horse can never have a good mouth; for if the bars be flat, round, and insensible, the bit will not have its effect; and, consequently, such a horse can be no more governed by his bridle, than if one took hold of his tail. These ridges are always more prominent in young horses than in those that are old. See LAMPAS.

BAR, in *Music*, denotes strokes drawn perpendicularly across the lines of a piece of music, including between each two, a certain quantity or measure of time, which is various as the time is triple or common.

The use of bars in music is a modern invention. They cannot be traced higher than the year 1574, and seem not to have been in general use till about the middle of the 17th century. It is not easy to imagine how music in many parts could be composed without bars, or how the maxima, or large, equal to eight femibreves, could be divided into bars of one or two femibreves in each. See BATTUTA, and TIME-TABLE. A double bar implies the end of a strain. When double bars are dotted on both sides, thus,

the dots imply a repetition of each strain; but if dotted only on one side, that strain only which precedes or follows the dots, is to be repeated.

BAR-Master, in *Mining*, he who keeps the gage or dish, to measure all miners ore; he, or his servant, being always to be present when it is measured.

BAR, among *Printers*, denotes a piece of iron with a wooden handle, whereby the screw of the press is turned in printing.

BARA, in *Ancient Geography*, an island of Italy, in the vicinity of Brundisium. Festus says, that the inhabitants of this island built the town of Barium.—Also, a port of Asiatic Sarmatia.

BARA, in *Geography*. See BARRA.

BARABA, in *Ancient Geography*, the name of a metropolitan city of Arabia Felix, according to some copies of Ptolemy and Ammianus Marcellinus.

BARABA, in *Geography*, a steppe or moor in the Russian empire, occupies the space between the Irtysh and the Oby, southward of the mountain, northward to the farther side of the Tara, and beyond the river Tuy. This extensive region, in length from north to south exceeding six hundred verst, and full four hundred in breadth from west to east, is one continued flat, scarcely interrupted by a single hill, though containing many fresh water lakes, with some of bitter, and a few of common salt. This plain is for the most part of a good black soil, having the face of it enlivened by a number of pleasant forests of birch. All serving to shew, says Mr. Falk, that the Baraba must have formerly been one general bed of waters, and since more morassy and replete with lakes than it is at present. Even within the memory of man, according to the affirmation of the Barabinses, the diminution of the lakes, and the exsiccation of the pools, reed-plots, and marshes, have been very observable, as well as the acquisitions thus made by the firm land. See Tooke's View of the Russian empire, vol. i. p. 149.

BARABALEMO, a river on the coast of Africa, six leagues east from the river of St. Barbara, east from cape Fermosa.

BARABENSIS, in *Entomology*, a species of GRYLUS

(*Locusta*) found about the pine-trees in the sandy deserts of Baraba. The wing-cases are pale and sprinkled with brown dots; wings transparent and pale yellow; veins and dots at the margin, and tip brown. Pallas. Size of gryllus tibialis.

BARABIACO, in *Geography*, a town of Italy, in the Milanese, situate on the Colona, 12 miles west of Milan.

BARABIELLO SAND, lies at the bottom of Bengal bay, within the river of Hughly.

BARABINIANS, a nation of the Russian empire. On entering the vast region of Siberia by the west, the first country we come to is that of the Barabinians. The large steppe, inclosed between the Oby and the Irtysh, and reaching as far as the Altay mountains, is called Barabina; this appellation the Russians have corrupted into Baraba; the people who occupy that desert they call Barabintzi, or Barabinians. The Barabinians, at the time of the conquest of Siberia, had already suffered too much from the turbulence and ferocity of their neighbours, for being able to raise themselves to a numerous population; and, remembering nothing but their misfortunes, they have forgotten whether they ever were governed by sovereigns of their own. At length, successively oppressed by the Kirghises and the Soongares, they at present enjoy tranquillity under the protection of Russia, who, in consideration of an easy tribute, takes charge of their defence. A mixture of several nations is discernible among them. They have, in general, the Tartarian physiognomy; but a flat face; the long eyes and little opened, and the hanging ears, are testimonies that some of them are of Mongolian race. The Soongares, their conquerors, at different times lived among, and probably are the progenitors of the Barabinians with Kalmuc countenances. The idiom of the Barabinians is a dialect of the Tartar language, and bears witness to their primeval origin. It is corrupted, but less than that of the Bashkirs. They live, however, in equal ignorance, and scarcely any of them know how to read. The humid vapours that arise in their steppe, and give a density to the atmosphere, render the inhabitants fallow and phlegmatic; their indifference and their apathy border on stupidity. In respect to them we might be tempted to adopt the expression of le Cat, and regard them, not so much as men animated by the heat of the blood, and the spirituous fluid of the nerves, but as hydraulic machines. This machinal state corresponds with their misery, and enables them to endure it without pain. Temperate alike in their amours and in their diet, with desires so feeble and so confined as to be easily gratified, they know nothing of robbery or theft; they are even ignorant of lying, having no use for it except for covering a slight fault, in order to gain time for repairing it. They have stationary habitations for the winter; and sow a little barley or oats, sometimes a small matter of hemp; but their culture is always of scanty production; their steppe, poor in game, but ill requites the fatigues of the hunter. They derive a slender profit from their flocks and herds, and a great number of fishermen owe their subsistence to the lakes. It is not uncommon in winter for the snow to envelope their huts in such manner that they could not get out were they to neglect to make a passage through the roof. Their summer dwellings are covered only with mats. Their herds, by no means numerous, though forming their principal wealth, consist of horses and horned cattle; the humidity of the soil hardly allows them to rear a few sheep. A great number of them possess not a single head of cattle; and a man passes for opulent who has from five to twenty horses, with still fewer horned cattle. It is not long since the richest man of the nation possessed seventy horses. It should seem that their droves would increase since they have no longer to dread the ravages

ravages of the Kirghises; but a mortality among their cattle filled up the measure of their wretchedness, when they thought it drawing near to its end. Exempted from other cares than those of the pastoral life, all have leisure to follow the fishery; they preserve the fish without salting, by letting it dry on the ground. Awkward in the use of the bow, they are obliged to take the game in snares, in nets, or by the aid of their dogs. These animals are excellent couriers, and their masters would not truck a good dog against a horse.

The women dress the skins of the birds that frequent the lakes, making them into pelisses, which they sell. These pelisses are very warm, last a long time, and are impenetrable to moisture. Every village has a chief, and each district its yaouta, who is a sort of prince. The nation grants them no revenue; all they get by their elevation is the pleasure of being respected, and of seeming to be obeyed. Consulted less as judges than as arbitrators, it is easy for them to settle disputes between pleaders, to whom it is almost the same thing to gain or to lose their cause, and they are scarcely capable of conceiving a desire.

It has been said, that the Mohammedans never attempt to make proselytes; this seems to be a mistake. Towards the middle of the late century, the Barabians were still devoted to Shamanism, when they were converted to Mohammedanism by the zeal of some neighbouring Moulahs, who came and preached in their steppes. At present they have several huts which they call mosques, some men who cannot read, whom they call priests, and by changing their faith they have only acquired a few additional superstitions.

BARACE, a town of France, in the department of the Mayne and Loire, and chief place of a canton in the district of Chateaufort, four leagues N.N.E. of Angers, and two E. S.E. of Chateaufort.

BARACE, or *Becare*, in *Ancient Geography*, a town of India on this side of the Ganges, in the gulf of Cantli, according to Ptolemy. It was situated at the mouth of the river, which passed to Neloonda, according to the author of the Periplus of the Erythrean sea. It was a more commodious port, and better stored with merchandise than Muziris, from which it was not far distant; and as the pepper of Cottonara was brought to this place in small boats, it may be concluded, that Barace was within, or near to the country of Canara, which produces the best pepper in those parts at the present day. Major Rennell says, that after much investigation, he cannot apply to any particular spot these ports of Muziris and Barace; for the Malabar coast abounds with ports of similar description; however, from the lights furnished by Pliny and Ptolemy, he conceives they were situated between Goa and Tellicherry, and that the modern Meerzaw or Merjee is the Muziris of the ancients, and Barcelore or Bassinore, which is one of the principal pepper factories at present, their Barace. M. d'Anville supposes Barace to be Nelynda, which Rennell takes to be Neli-faram. Rennell's Mem. Introd. p. 38.

BARACK, or BARRACK, BARAQUE, a hut or little lodge for soldiers in a camp.

The word comes from the Spanish *larracas*, little cabins, which fishermen make on the sea-shore.

Those for the horse were formerly called barracks; and those for the foot, huts; but barack is now used indifferently for both.

Baracks are generally made by fixing four forked poles in the ground, and laying four others across them; afterwards they build up the walls with fods, wattles, or what the place affords; and the top is planked, thatched, or covered with turf, as they have convenience.

When the army is in winter quarters, the soldiers usually build barracks; in the summer they are content with their tents.

BARACKS is also more generally applied to buildings to lodge soldiers in fortified towns, or others. Thus we say the barracks of the Savoy, of Dublin, &c.

Baracks, when damp, are greatly prejudicial to the health of the soldiers lodged in them; occasioning dysenteries, intermitting fevers, coughs, rheumatic pains, &c. For which reason quarter-masters ought to be careful in examining every barack offered by the magistrates of a place; rejecting all ground-floors in houses that have either been uninhabited, or have any signs of moisture.

BARACK-ALLOWANCE, a specific allowance of bread, beer, coals, &c. to the regiments stationed in barracks.

BARACK-GAARD, the principal guard of a regiment in barracks; the officer of which is responsible for the regularity of the men, and for all prisoners duly committed to his charge while on that duty.

BARACK-MAJOR-GENERAL, a staff-officer at the head of the barack department, who has a number of barack-masters and deputies under him, that are stationed at the different barracks. He has an office and clerks for the dispatch of business; and to this office all reports, &c. respecting the barack department are made.

BARACOA, in *Geography*, a sea-port town at the north-east end of the island of Cuba, having a good harbour for small vessels, but not for large ships; distant about seventeen leagues north-east from St. Jago. N. lat. 21° 4'. W. long. 76° 10'.

BARACUM, in *Ancient Geography*, a town of the interior part of Africa, which Pliny mentions among the conquests of Cornelius Balbus.

BARACURA, a commercial town of India, on the other side of the Ganges. Ptolemy.

BARACUS, a river of India, in the southern part of the island of Taprobana. Ptolemy.

BARAD, a town of Palestine, in the southern part of the tribe of Judah, according to the book of Numbers.

BARADELUS, or ZANZALUS, JACOBUS, in *Biography*, an obscure monk of the sixth century, who revived the sect of the Monophysites, when it was just expiring, to its former prosperity and lustre. For this purpose, after having been ordained to the episcopal office by a few captive bishops, he travelled on foot through the whole east, established bishops and presbyters every where, revived the drooping spirits of the Monophysites, and produced such an astonishing change in their affairs by the power of his eloquence, and by his incredible diligence and activity, that when he died bishop of Edessa, A. D. 588, he left his sect in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. This poor monk had the wisdom to concert the means of success, as well as activity to put them in execution; for he almost totally extinguished all the animosities, and reconciled all the factions, that had divided the Monophysites; and when their churches became so numerous in the east, that they could not all be comprehended under the sole jurisdiction of the patriarch of Antioch, he appointed, as his assistant, the primate of the east, whose residence was at Tagritis, on the borders of Armenia. The laborious efforts of Jacob were seconded in Egypt and the adjacent countries by Theodosius, bishop of Alexandria; and he became so famous, that all the Monophysites of the east considered him as their second parent and founder; and they are to this day called Jacobites, in honour of their new chief, Moheim Eccl. Hist. vol. ii. p. 145. See MONOPHYSITES. and JACOBITES.

BARADERES, in *Geography*, a small bay on the north coast of the peninsula at the west end of the island of St. Domingo, or Hispaniola. It is almost land-locked, having a small island near the bottom in the south-east corner. N. lat. $18^{\circ} 42'$. W. long. $73^{\circ} 37'$.

BARADY, **BARRADY**, or *Barrada*, a river of Syria, called by the ancients Chrysochoras, or the golden river; and by the Syrians, Parpar; which, rushing from Antilibanus, descends to Damascus, and is there divided into endless streams, for the supply and decoration of that city; but uniting again at some distance from it, they lose themselves in a morass. The rivers Abana and Pharpar, the names of which are lost among the Arabian geographers, Maundrell supposes must have been branches of this river Barady, which issues out of the rock.

BARÆ, in *Ancient Geography*, a people of India, placed by Ptolemy near the Ganges.

BARATAT, in *Geography*, a town of Africa, in the kingdom of Fonia, seated on a peninsula formed by the river Gambia and two other rivers.

BARAGAZA, a town of Ethiopia, on the Red Sea, mentioned by Pliny.

BARALIPTON, a term in *Logic*, denoting the first indirect mode of the first figure of syllogisms.

A syllogism in baralipson is when the two first propositions thereof are universal affirmatives, and the third a particular affirmative; the middle term being the subject of the first, and the attribute of the second.—For example:

“BA Every evil ought to be feared:

RA Every violent passion is an evil:

LIP Therefore something that ought to be feared is a violent passion.”

See letters A and I, and SYLLOGISM.

BARALLOTS, **BARALOTTI**, the name of a sect at Bologna in Italy, who had all things in common, even their wives and children. They gave, it is said, into all manner of debauchery, and were also termed *conspirers*.

BARAMATIS, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

BARA-MAREKA, in *Botany*. See *DOLICHOS*.

BARAN, in *Geography*, a river of Hindostan, in the province of Cabul, which is joined by the rivers Chugan-ferai, Alifshung, and Alikar, in the district of Kameh, and then runs eastward or south-eastward. But it is not absolutely certain whether these confluent rivers join the river of Cabul above Pailshawur, or whether they form a separate river, and pass by Bijore and Sewad.

Major Rennell thinks the former to be the most probable, and that the confluent river receives the name of Kameh, from the district in which the junction takes place, and then communicates it to the Cabul river, during the remainder of its course. Rennell's Mem. p. 156.

BARANCA, or **ST. JAGO**, in *Geography*, a river belonging to Mexico, in North America, which directs its course to the west coast, and falls into the Pacific ocean about ten leagues west by north from Xatisco bay.

BARANCA del Malambo, a sea-port town of South America, in the country of New Castile or Terra Firma, on the east side of the Rio Grande, at the mouth of the river Magdelana, with a good harbour. This is a place of considerable commerce; as the merchandise of New Granada is brought down hither by boats, and conveyed to the bay about 40 miles below the town, or else directly to Santa Martha, by a branch of the great river; the chief article is salt, which is produced in the neighbourhood of the town. It is distant 25 miles north-east from Carthagena. N. lat. $11^{\circ} 40'$. W. long. $75^{\circ} 30'$.

BARANCAS, **LAS**, a town of North America, in the province of New Mexico, 45 miles S. S. E. of Santa Fé.

BARANEI-STANITZ, a town or settlement in Siberia, on the Lena, 52 miles north-east of Vitimskoi. N. lat. $54^{\circ} 50'$. E. long. $113^{\circ} 14'$.

BARANGE, in *Ancient Geography, a town of Asia, in Hyrcania. Ptolemy.*

BARANGI, officers among the Greeks of the lower empire, whose business it was to keep the keys of the city-gates where the emperor resided.

Codinus says, that the barangi were those who stood guard at the door of the emperor's bed-chamber and dining-room.

Codinus and Curopalata observe, that the name is English, formed from *bar*, to shut; and that the barangi were Englishmen by country; Anglo Danes, who, being driven out of England, were received into the service of the emperor of Constantinople, and made guards or protectors of his person. Whence they are called in Latin, by Cujaccius, *protectores*; by others, *securigari*, as being armed with a battle-ax, *securis*. Codinus adds, that they still spoke the English tongue. Anna Comnena says, the barangi came from the island Thule, by which is doubtless meant our island. Yet Nicetas makes them Germans; a mistake easy to be made at that distance, considering the relation the Anglo-Saxons bore to Germany. There were barangi as early as the emperor Michael Paphlagonius, in the year 1025, as appears from Cedrenus; but they were then only common-soldiers, not a life-guard.

Their commander was called *αρχαρχος*, as importing a person who always followed the emperor.

BARANI, &c. Steller Kamts. *Stepnie Baranni*, J. G. Gmel. it. Sibir. &c. in *Zoology*, names given to the *Ovis Ammon*, Gmel.; and *Capra Ammon*, Linn.

BARANILLO, in *Geography*, a town of Italy, in the kingdom of Naples, and comtat of Molise, nine miles S. S. E. of Molise.

BARANOW, a town of Poland, in the palatinate of Sandomir, sixteen miles south of Sandomir.

BARANOWKA, a town of Poland, in the palatinate of Volhynia; 40 miles N. N. E. of Constantinow.

BARANZANO, **REDEMPTUS**, in *Biography*, a Barnabite friar, was born in 1590, at Saraville, a town of Verceil, in Piedmont, and obtained eminence at the commencement of the seventeenth century, by daring to abandon the Aristotelian method of philosophy. That he coincided in his ideas with those of the illustrious lord Bacon, appears from a letter written to him on this subject, by this restorer of philosophy, in June 1622, and preserved in the third volume of “Niceron's Memoirs.” Having taught mathematics and philosophy at Anneci, he went to Paris, and formed an intimate friendship with La Mothe le Vayer, who speaks of him (*Oeuvr.* 12mo. tom. iv. p. 172.) as one of the first wits of the age. He adds, that this honest Barnabite had several times assured him, but always with submission to the good pleasure of God, that he would appear to him, if he should depart first out of this world. However his promise was not fulfilled, and he verified the sentence of a Latin poet, Catullus, *Epigr.* iii.

“Qui nunc it per iter tenebricosum
Illuc, unde negant redire quanquam.”

“He passed the dark and dreary way

From whence there's no return to the bright genial day.”

He died at Montargis in 1622: His works are “*Urano-scopia*,” or the universal doctrine of the heavens, printed in folio, in 1617; “*Campus Philosophicus*,” the first part of

his

his Summary of Philosophy, as taught at Anceci, printed at Lyons, in 8vo. in 1619; and "De Novis Opinionibus Phycis," printed at Lyons, in the same year. Gen. Dict.

BARAO, in *Geography*, a town of Spain, in Arragon, two leagues from Jaca.

BARA-PICKLET, bread made of fine flour kneaded with barm, which makes it very light and spongy: *bara* being the Welch for bread.

BARAQUICIMITO, in *Geography*, a town in Terra Firra, South America, in the province of Caracas, and in the head waters of Oronoko river, about 80 miles south from Valencia, and 175 north-west from Calabeza. N. lat. 8° 55'. W. long. 66° 55'.

BARASA, in *Ancient Geography*, a town of Palestine, according to Josephus.

BARASZE, in *Geography*, a town of Poland, in the palatinate of Volhynia, 36 miles N.N.W. of Zytomiers.

BARATHIER, BARTHELEMY, in *Biography*, an Italian lawyer of the 15th century, was born in Placentia, and taught the Roman feudal law at Pavia and Ferrara, which he ranged anew, and then formed a text book for the school. The work was printed at Paris in 1611, under the title "De Feudis Liber Singularis;" and in 1695, by Schilter, under its true title "Libellus Feudorum reformatus." Moreri.

BARATHRUM, from *βαραθρον*, signifying the same, among the *Ancient Athenians*, a deep pit belonging to the tribe Hippothoontis, into which condemned criminals were cast headlong.

The barathrum was a dark noisome hole, having sharp spikes at the top, to prevent any escape, and others at the bottom to pierce and lacerate the offender.

From its depth and capaciousness, the name came to be used proverbially for a miser, or a glutton, always craving. In which sense, the word *barathrum* is used among the Latin poets. Thus Horace, *Epist. l. i. ep. 15. v. 631.*

"Pernicies, et tempestas, barathrumque Macelli,
Quicquid quaesierat, ventri donaret avaro."

It is also used for a common prostitute, by Plautus (*Bacchid. i. 2. 44.*), thus:

"O barathrum, ubi nunc es? ut ego te usurpem libens!"

BARATHRUM is also used, in *Physiology*, to denote certain baleful caverns, inaccessible on account of their fetid or poisonous fumes.

These amount to the same with what others call *seffa eharonite*.

BARATIER, JOHN PHILIP, in *Biography*, a learned German, was born in 1721, at Schwobach near Nuremberg. Under the instruction of his father he is said to have understood the Greek, Latin, German, and French languages, when he was five years old; and he acquired also the knowledge of the Hebrew in one year, so as to be able to read the historical books of the bible: and at the age of nine years, he could not only translate the Hebrew text into Latin or French, but also re-translate these versions into Hebrew. At this age he could also repeat memoriter the Hebrew psalter, in consequence of merely reading it with his father. Before he had completed his tenth year, he composed a Hebrew lexicon of rare and difficult words, with curious critical remarks. In 1731, he was matriculated in the university of Altdorf; and in this year he wrote a French "letter to M. le Maitre, minister of the French church at Schwobach, on a new edition of the bible, Hebrew, Chaldaic, and Rabbinical," which letter is preserved in the twenty-sixth volume of the "Bibliothèque Germanique." In 1734, the margrave of Anspach granted him a pension of fifty florins a year, and allowed him the free

use of books from the library at Anspach. As the fruits of his application to study, his translation from the Hebrew, with historical and critical notes and dissertations, of "The Rabbi Benjamin's Travels in Europe, Asia, and Africa, containing an account of the state of the Jews in the twelfth century," was published, in two volumes 8vo. at Amsterdam, in 1734; the author being at this time in his thirteenth year: and the whole work is said to have been finished in four months. Notwithstanding the extent of his philosophical pursuits, this astonishing youth applied to the study of mathematics and philosophy with such success, that he devised a method of finding the longitude at sea, which was laid before the Royal Academy of Sciences at Berlin, in a long letter, dated Jan. 21, 1735, the day in which he completed his fourteenth year. His letter being well received, he determined to visit Berlin, with a view of enforcing his project: but in his way thither he passed through Hall, where Ludewig, the chancellor of the university, offered to confer upon him the honorary degree of master of arts. Flattered by this proposal, Baratier immediately, in the presence of many professors, drew up fourteen theses in philology, ecclesiastical history, and philosophy, which were printed the same night, and which he supported for three hours the next day with great applause; upon which he was admitted master of arts in philosophy. He then pursued his journey to Berlin; and, in the presence of the mathematical class, replied in French to some objections that were urged by M. de Vignoles, the rector, against his scheme; and he then proposed, in Latin, the plan of an astronomical instrument, which he offered to execute. M. Jablonski, the president, reported, that he had examined Baratier, in the king's presence, and that he had found him well acquainted with rabbinical learning, the oriental languages, and ecclesiastical history; and he was then, with the usual form, admitted a member of the society. Upon his return to Hall with his father, he directed his attention to theology, and wrote an answer in Latin to Crellius, who, under the assumed name of Artemonius, had published a Socinian interpretation of the introduction to the gospel of St. John. This was intitled "Anti-Artemonius, and published at Nuremberg, in 8vo. in 1735. It was accompanied with a "Dissertation on the three dialogues, commonly attributed to Theodoret," intended to invalidate their authenticity. In 1737, he defended this piece against the strictures of the journalists of Trevoux, in another dissertation, which was printed in the forty-eighth volume of the "Bibliothèque Germanique." In the fortieth volume of the same journal, there is another dissertation of Baratier "On two works attributed to Athanasius." Baratier being obliged to confess his ignorance of the public law, in reply to the inquiry proposed to him by the king of Prussia, was commanded by the king to go and study it, before he called himself a learned man. Such was his literary ambition, that he applied immediately to the study of it, and after fifteen months he supported a thesis on the subject with great credit. The uninterrupted exertion of his faculties soon impaired his constitution, which was naturally delicate and feeble; and after languishing in a decline for several months, Baratier died at the age of nineteen years eight months and seven days. His attainments were surprising; and yet it is said that, before he was ten years of age, he was accustomed to lie in bed twelve hours, and ten hours from that time to his death. The facts above adduced may seem truly astonishing; but they are founded upon unquestionable testimony. Some few examples of a similar kind have occurred; however they should by no means be contemplated as patterns of imitation.

or as models of perfection. "The poplar, which soon becomes a lofty tree, will soon decay: the strong and sturdy oak, whose majestic trunk stands unimpaired through centuries, requires a century to bring it to maturity." Formey's *Life of Barater*. *Nouv. Dict. Histor.*

BARATO, CAPE, in *Geography*, lies on the coast of Italy, on the north side of the peninsula of Pionbin, and about S.S.E. from Leghorn. It has a small bay on the S.W. before which is anchorage.

BARATRUM, in *Antiquity*, denotes, according to Hesychius, sacred games, celebrated at Theprotia, in which the most robust of the combatants was crowned.

BARATRY, BARETRY, or BARRETRY, in *Law*, signifies the moving and maintaining suits in disturbance of the peace; and the taking and detaining houses, lands, &c. by false inventions. 8 Rep. 37. 1 Hawk. P. C. 243. The word *baratterie*, in French, signifies *misdeemeanor, fraud, deceit*: it is derived from the old word *barat*, which signifies any imposition; whence also they said *baratter*, to *impose on any one*.

The punishment for this offence, in a common person, is by fine and imprisonment; but if the offender belongs to the profession of the law, a barretor who is thus able as well as willing to do mischief, ought also to be disabled from practising for the future. However it seems clear that no general indictment, charging the defendant with being a common oppressor and disturber of the peace, and stirrer up of strife among neighbours, is good without adding the words "Common Barretor," which is a term of art appropriated by law to this purpose. 1 Mod. 288. 1 Sid. 282. Cro. Jac. 526. 1 Hawk. P. C. c. 81. § 9. No man can be a barretor in respect of one act only; and it hath been holden, that a man shall not be adjudged a barretor for bringing any number of suits in his own right, though they are vexatious, especially if there be any colour for them; for if they prove false, he shall pay the defendant costs. 1 Rol. Abr. 355. 3 Mod. 98. A common solicitor who solicits suits, is a common barretor, and may be indicted thereof, because it is no profession in law. 1 Danv. Abr. 725. It is enacted by statute 12 George I. c. 29. that if any one, who has been convicted of forgery, perjury, subornation of perjury, or common barretory, shall practise as an attorney, solicitor, or agent, in any suit, the court upon complaint, shall examine it in a summary way; and, if proved, shall direct the offender to be transported for seven years. To this head may also be referred another offence of equal malignity and audaciousness; that of suing another in the name of a fictitious plaintiff; either one not in being at all, or one who is ignorant of the suit. This offence, if committed in any of the king's superior courts, is left, as a high contempt, to be punished at their discretion. But in courts of a lower degree, where the crime is equally pernicious, but the authority of the judges not equally extensive, it is directed by statute 8 Eliz. c. 2. to be punished by six months imprisonment, and treble damages to the party injured. Blackst. Com. v. iv. p. 134.

BARATRY, in a *Marine Sense*, is the master of a ship, or the mariners, cheating the owners or insurers, whether it be done by running away with the ship, sinking her, deserting her, or embezzling the cargo.

Baratry of mariners is so epidemical on ship-board, that it is rare if the master, be his industry ever so great, can prevent it, by reason of the encouragement one knavish sailor gives another; yet the law, in such cases, imputes the offences of the mariners to the negligence of the master, and from him the merchant is to seek for remedy for all goods or merchandise lost, embezzled, or otherwise damaged.

By the French ordonnances, insurers are not obliged to make good the loss or damage accruing to a vessel, or its lading, by the fault of the master or crew, unless by the forms of the policy, they may be made accountable for the baratry of the patron. A master who, without necessity, takes up money on the body, provision, or tackling of a ship, or sells the effects on board, or, in his account of average, sets down fictitious expences, shall pay the value, be declared unworthy of being master, and banished the port where he ordinarily resided. In some cases, he is also subject to corporal punishment, and even to death, where it appears he willingly threw away the ship.

BARATRY is also used for bribery or corruption in a judge, giving a false sentence for money.

BARATRY is also used in making of contracts, sales, or the like.

BARATTA, or BARATTA, in *Ancient Geography*, a town of Lycaonia, mentioned by Ptolemy.

BARAVEL, Sr., in *Geography*, one of the Ladrone islands, lies south of the island of Guam, and was one of those discovered by Magellan, and described by Pigafetta. Besides this, there are also between 10° and 13° N. lat. the islands of Ban and Bota, and the shoals of Santa Rosa. N. lat. 12° 44'. E. long. 142° 28'. See LADRONES.

BARAVOE, a bay and village, on the north-east coast of the island of Shetland.

BARAWNAY, a town of Hindostan, in the country of Candahar, forty-miles N.E. of Burhampour, and seventy-four S.S.E. of Indore.

BARAZA, in *Ancient Geography*, a town of Armenia Major. Ptolemy.

BARB, ST. in *Geography*. See ST. BARBARA.

BARB, in *Ornithology*, is used for the *Barbury pigeon*, the COLUMBA NUMIDICA of Moore.

BARBA, in *Ancient Geography*, a town of Spain, in Betica, placed in the Itin. of Antonin, twenty miles from Ollippo, and twenty four miles from Antiquaria.

BARBA, in *Geography*, a town of North America, in the country of Mexico, and province of Colla Rica, twenty-two miles S.S.W. of Cartago.

BARBA Aron, in *Botany*, a name given by some authors to the common great house-leek.

BARBA Capræ. See SPIRÆA.

BARBA Jovis. See AMORPHA, ANTHYLLIS, CYTISUS, EBENUS, and PSORALEA.

BARBACAN, or BARBICAN, in the *History of our Ancient Fortifications*, was a sort of advanced work which frequently covered the drawbridge at the entrance of a castle.

In which sense, barbican amounts to the same with what is otherwise called, *antemurale, promurale, murus exterior*, or *outer wall*. In towns and large fortresses the barbicans were large and strong, frequently having a ditch and drawbridge of their own. (See Grose's *Hist. Eng. Army*, II. 2.) The term is still preserved in the ruins of several of our castles; a small stone work covering the gate of Bodiam castle in Suffex, is still called the barbican; and some work of a similar kind undoubtedly gave its name to one of the streets at the north-west end of ancient London. Barbicans are also mentioned in Framlingham and Canterbury castles. For the repairing of this work, a tax called barbicanage was levied on certain lands. Grose *Antiq. Pref.* i. 5.

BARBACAN is also used for a fort at the entrance of a bridge, or in the outlet of a city, having a double wall with towers. Such is that at one end of the wooden bridge at Rouen, which is still called by some *Barbacana*.

BARBACAN is also used for an aperture in the walls of a city,

city, through which to fire with muskets on the enemy. See EMBRASURE.

BARBACAN, in *Architecture*, denotes a long narrow canal or opening left in the walls for water to come in and go out at, when edifices are ruised in places liable to be overflowed; or to drain off the water from a terrace, or the like.

BARBACE POINT, in *Geography*, the east point of St. Pedro's channel, at the south-east end of the island on which the city of Cadiz is situated.

BARBACOS, a river on the coast of America, in the Pacific ocean, nearly east of the island of Gallo. Barbacos point is situated ten leagues from the river Tellember, in N. lat. $2^{\circ} 45'$. W. long. $73^{\circ} 55'$.

BARBADENSIS, in *Conchology*, a species of *VOLUTA* that inhabits the American ocean. The length of this shell is an inch and a half; shape tapering; colour reddish, with very fine transverse striae; aperture oblong-oval; spire obtuse. Figured only by Lister, t. 819. f. 53. Gmelin.

BARBADENSIS, in *Ornithology*, a species of *PSITTACUS*, the *ash-fronted parrot* of Latham. This bird is about the size of a pigeon, and inhabits Barbadoes; the general colour is green; orbits and front cinereous; crown, chin, cheeks, throat, and lesser wing-coverts yellow; greater ones blue; many of the primary quill-feathers violet on the outside, the rest red from the base, and the rest blue. Gmelin. The legs are ash; claws black.

BARBADOES, in *Geography*, one of the most important of the Caribbee islands in the West Indies, standing somewhat detached from the rest, about thirty-five degrees from the African islands of cape Verd. This island was probably first discovered by the Portuguese in their voyages from Brasil, and from them received its present name. It had then neither occupants nor claimants; the Charabees or Caribbees having deserted it. The Portuguese thought it not of sufficient importance for a settlement; and having furnished it with a breed of swine for the use of future navigators, they left it as they found it. The English, in 1605, finding it without inhabitants, took possession of the country by fixing a cross on the spot where James-town was afterwards built, with this inscription: "James king of England and this island;" but they formed no settlement. At this time it was overgrown with woods; but yet it furnished them with a supply of fresh provisions. They found here pigs, pigeons, and parrots; and the sea abounded with fish. Some years after this, a favourable report having been made of its beauty and fertility by the master and seamen of a ship of sir William Courteen, lord Ley, afterwards earl of Marlborough, obtained from king James I. a grant of the island to himself and his heirs in perpetuity. Accordingly Courteen, probably under the patronage of Marlborough, projected the establishment of a colony, and sent about 30 settlers to plant and fortify the island, who, in 1624, laid the foundation of James-town; and this was the first English settlement on the island. About this time, James Hay, earl of Cadiz, established a colony in the island of St. Christopher, and obtained from Charles I. a grant of all the Charibbee or Caribbee islands, including Barbadoes. This grant was contended by earl Marlborough; but at length a compromise took place; and in the earl of Carlisle's undertaking to pay the annual sum of 300l. to the earl of Marlborough and his heirs for ever, the latter waved his claims; and in 1627 the patent of the former passed the great seal, and he became the sole proprietor. However, the earl of Pembroke obtained a revocation of Carlisle's patent, and a grant to himself in trust for Courteen, who had projected the first settlement in the island. This grant was afterwards annulled, and the earl of

Carlisle was restored to the possession and privileges of which he had been for a short time deprived. Accordingly he proceeded to distribute lands to such persons as chose to comply with his laws; and a society of London merchants accepted 10,000 acres, on conditions which promised great benefit to the proprietors. These merchants sent over 64 persons, each of whom was authorized to take up 100 acres of land; and thus, in 1628, they established a new colony, which soon overpowered the settlement, and annihilated the interest of Courteen. In 1629, sir William Tufson was sent out by lord Carlisle as chief governor, and he distributed land, amounting to 15,872 acres, into 140 grants; and in 1630, passed several laws; among which was one for dividing the island into six parishes. During the civil war, the emigrations from the mother country was so great, that in 1650 it was computed there were 20,000 white men in Barbadoes, half of them able to bear arms, and furnishing a regiment of horse to the number of 1000. It seems that about this time the existing governor granted lands to all who applied, on receiving a gratuity for himself; and the claim of the proprietor, whether disputed in the island, or disregarded amidst the confusions at home, was at length tacitly relinquished.

The colony, enjoying an unlimited freedom of trade, flourished in a singular manner by its own efforts. In 1646, the son and heir of the earl of Carlisle, the original patentee, revived his claims as hereditary proprietor, and by treaty with lord Willughby of Parham, conveyed to him all his rights by a lease of 21 years, on condition of receiving one-half of the profits. Lord Willughby obtained a commission as chief governor; and was received by the inhabitants, who were warmly attached to the king's interest, with respect and obedience. But soon after his arrival, the regal authority in England was abolished.

Barbadoes, in 1651, was reduced to the obedience of the new republic, who appointed another governor. Upon the restoration of Charles II., lord Willughby applied for leave to return to his government of Barbadoes; against which the inhabitants, now apprized of his connection and contract with the earl of Carlisle, and apprehending that they were regarded by these lords as mere tenants at will of their possessions, remonstrated. They pleaded that they were the king's subjects, and solicited his majesty's support and protection. They objected to the claims of the earl of Carlisle, and insisted that the charter granted to him was void in law. The several allegations and claims of the parties concerned were referred to a committee of the privy-council; and it was finally ordered, that lord Willughby should repair to his government, and demand the grant and establishment by the assembly of a permanent and irrevocable revenue of $4\frac{1}{2}$ per cent. to be paid in specie, on all dead commodities, the growth of the island, shipped to any part of the world; and the money arising from this revenue was to be applied towards making provision for the earl of Kinnoul, the legal representative of lord Carlisle with respect to his rights in the West Indies, who had on this condition promised to surrender the Carlisle patent to the crown, towards paying the annuity to the earl of Marlborough, and towards the discharge of the creditors of both these noblemen. After the extinction of these incumbrances, it was stipulated, that the revenue, subject to the charge of 1200l. per annum to the governor, should be at the disposal of the crown. With these instructions, lord Willughby returned to his government in 1663. The planters were dissatisfied, and preferred complaints, which, however, were unavailing. At length, finding resistance vain, the assembly passed an act for the purposes that were required, dated Sept. 12. 1663. Thus the proprietary

government was dissolved, and the legislation of the island vested in the crown.

The island of Barbadoes is about 21 miles in length and 14 in breadth, and contains 106,470 acres of land, most of which is under cultivation. The soil in the low lands is black, somewhat reddish in the shallow parts; on the hills of a chalky marl, and near the sea generally sandy. Of this variety of soil, the black mould is best suited for the cultivation of the cane, and, with the aid of manure, has produced as great returns of sugar, in favourable seasons, as any in the West Indies, the prime lands of St. Kitt's excepted. About the year 1670, we are assured that Barbadoes could boast of 50,000 whites, and upwards of 100,000 black inhabitants, whose labours are said to have given employment to 60,000 tons of shipping. This account may probably have been exaggerated; but it is certain that the inhabitants of this island have decreased with a rapidity seldom known in any other country. It appears by authentic returns, that the number of its whites, in 1724, amounted to no more than 18,295, and that of its negroes in 1753 was no more than 69,870. In 1786, the numbers were 16,167 whites, 838 free people of colour, and 62,115 negroes. It appears also that the annual produce of this island, particularly of sugar, has decreased in much greater proportion than in any other of the West Indian colonies. Posslethwayte states the crop of sugar, in 1736, at 22,769 hogheads of 13 cwt. which is equal to 19,800 of 15 cwt.; and the author of the "European Settlements," published in 1761, calculates the average crop at 25,000 hogheads. If this statement be just, the island has fallen off nearly one-half in the annual growth of its principal staple. In an average of eight years, from 1740 to 1748, the exports were 13,948 hogheads of sugar of 15 cwt.; 12,884 puncheons of rum of 100 gallons; 60 hogheads of melasses; 4,667 bags of ginger; 600 bags of cotton; and 327 gourds of aloes. The exports on an average of 1784, 1785, and 1786, had fallen to 9,554 hogheads of sugar; 5,448 puncheons of rum; 6,320 bags of ginger; 8,331 bags of cotton; exclusively of some smaller articles, as aloes, sweetmeats, &c. of which the quantities are not ascertained. The dreadful succession of hurricanes, which had occurred within the last twelve years, has, without doubt, contributed to this great defalcation. The capital of this island was scarcely risen from the ashes to which it had been reduced by two dreadful fires, when it was torn from its foundations, and the whole country made a scene of desolation by the storm of the 10th of October in 1780; in which 4,326 of the inhabitants, blacks and whites, miserably perished; and the damage to the country estimated at 1,320,564l. 15s. sterling. In the year 1792, the produce of sugar was 11,073 hogheads, 125 tierces, 2,698 barrels; of melasses 188 hogheads; of rum 5,064 hogheads, 512 barrels; of ginger 3,046 bags and barrels; of aloes 515 gourds; and of cotton 974,178 pounds. From the great increase in the export of sugar in this year compared with several of the preceding years, and decrease in that of the minor staples, it seems probable that the advanced price of that article in Europe has encouraged the cultivation of it in plantations which had been formerly abandoned or appropriated to a different kind of culture. The average of the number of negro slaves in Barbadoes for seven years, from 1786 to 1792, was 63,271, of slaves imported 4363, and the average amount of taxes, during the same period, was 9,530l. 14s. 1d. The taxes consist of a capitation tax on negroes; a tax on sugar-mills, dwelling-houses, and carriages, together with an excise, &c. on wines imported. Besides which there is a parochial tax on land, amounting on an average throughout the island to about two shillings per

acre, and an assessment in labour for the repair of the high-ways. The whole is altogether exclusive of the heavy duty of $4\frac{1}{2}$ per cent. to the crown.

Barbadoes is divided into 5 districts and 11 parishes; and contains 4 towns; viz. Bridgetown, Oistins or Charles-town, St. James's formerly called the Hole, and Speight's-town; Bridgetown is the capital, and the residence of the governor, whose annual salary is 2000l. per annum, paid out of the exchequer, and charged to the account of the $4\frac{1}{2}$ per cent. duty. The form of the government of this island resembles that of Jamaica, except that the council is composed of 12 members, and the assembly of 22. The most important variation respects the court of chancery, which in Barbadoes is constituted of the governor and council, whereas in Jamaica the governor is sole chancellor. On the other hand, in Barbadoes, the governor sits in council, even when the latter are acting in a legislative capacity, which would be considered, in Jamaica, as improper and unconstitutional. It may also be observed, that the courts of grand sessions, common pleas, and exchequer, in Barbadoes, are distinct from each other; and not, as in Jamaica, united and blended in one supreme court of judicature. The heat of the climate is moderated by the trade-winds, and the air is pure. Its products, besides what we have already mentioned, are the palm, tamarinds, figs, bananas, cedar, mastic, cacao, papas, guavas, and palmettoes. Barbadoes is situated in N. lat. $13^{\circ} 10'$. W. long. 59° . See Edwards's History of the West Indies, vol. i. p. 321—350.

BARBADOES *Bastard-Cedar*, in *Botany*. See CEDRELA.

BARBADOES *Cherry*. See MALPIGIA.

BARBADOES *Flower-fence*. See POINCIANA.

BARBADOES *Gooseberry*. See CACTUS *Perefskia*.

BARBADOES *Wild-Olive*. See BONTIA.

BARBADOES *Tar*, in the *Materia Medica*. See PETROLEUM *Barbadense*.

BARBADÓR, BABABERA, or Cape BARBA, in *Geography*. See Cape BABA.

BARBALIS, in *Entomology*, a species of PHALÆNA, that feeds on the *trifolium pratense*. The antennæ pectinated; feelers shorter; anterior thighs with a projecting beard. Fabricius.

BARBALISSUS, in *Ancient Geography*, Beles, a considerable town of Asia, in Syria, near the Euphrates, E.S.F. of Hierapolis. This is the *Barbarissus* of Ptolemy, according to M. D'Anville.

BARBANA, or BARBENNA, a river of Illyrium, which sprang from the Labeatid Marsh, according to Livy.

BARBANA, in *Geography*, a town of Istria, seven miles N.N.E. of Pola.

BARBANO, a small island in the northern part of the Adriatic, near the coast of Friuli. N. lat. $45^{\circ} 45'$. E. long. $13^{\circ} 28'$.

BARBANOLA, CAPE, is the south of Smyrna gulf, on the coast of Asia, at the east extremity of the Mediterranean, and nine leagues S. by W. from Porto Gero.

BARBAR, a province of Abyssinia, separated from Atbara by the river Tacazzé; the capital of which is Gooz, which see.

BARBARA, in *Conchology*, a species of HELIX, with an oblong, coarse, imperforated shell, with eight wreaths, and a subrotund lunated aperture. This kind inhabits Algira. Somewhat resembles *helix pupa*, but is not above half the size, being usually about the bigness of a barley-corn. Gmel. &c.

BARBARA, in *Entomology*, a species of FORMICA that inhabits Africa, and is as large as *F. berulana*. It is black, with the head, antennæ, and extremity of the legs ferruginous;

ginous; petiole with two tubercles. Fabricius, &c. The head is large; first joint of the antennæ large and black,

BARBARA, *Bay of St. in Geography*, lies on the south-west coast of Terra del Fuego in South America, where at two leagues S. by E. from cape Noir, are two rocky islets; but no land is seen at E.N.E. from the cape, where is probably the channel of St. Barbara; which opens into the straits of Magellan. Cape Desolation lies to the S.E.; the entrance is open, and it will admit a large fleet of ships.

BARBARA, *St. Channel of*, lies on the south shore of the straits of Magellan, between bay de Choiseul and Cascade bay. It is supposed to communicate with the bay of St. Barbara; its entrance on that side being opposite to James's island. It has been thought of importance to explore this supposed channel from the strait; because it would afford, if found good, a quick and safe passage into the Southern Pacific ocean.

BARBARA, *St. Island*, the southernmost of two islands bearing north and south on the east side of the canal grande, or principal channel, from cape Frio, on the coast of Brazil, to the bay of All Saints. It has two good roads; one on the south-west, and another on the north-east.

BARBARA, *St.* the chief town of New Biscay, in the audience of Galicia, in New Spain, in North America.

BARBARA, *St. River*, lies on the coast of Africa, to the east from cape Fernosa, and six leagues west from Barabalemo.

BARBARA, *St. Canal of*, lies on the north-west of America, near the coast of New Albion; the north-west point of entrance into which is called point Conception; in N. lat. $34^{\circ} 32'$. E. long. $239^{\circ} 54'$. The westernmost, or first island, forming this canal, is called in one Spanish chart St. Miguel, in another St. Barnardo; the next is called in one chart Santa Rosa, in the other St. Miguel; and nearer the canal is a third island, upon which is a high hill called in the Spanish charts Santa Cruz. The coast continues in an easterly direction about 23 miles from point Concepcion to a point where it takes a southerly turn, from whence the country gradually rises to mountains of different heights. In the vicinity of the shores, which are composed of low cliffs or sandy beaches, are produced some stunted trees and groveling shrubs; and, notwithstanding the dreary appearance of the coast, it seems to be well inhabited, as several villages may be perceived at no great distance from one another, in the small bays or coves that form the coast. The inhabitants use canoes of wood, decorated with shells; and traffic with their fish and ornaments for spoons, beads, and scissars. They seemed, says Vancouver, to possess great sensibility and vivacity, and yet conducted themselves with the most perfect decorum. Their native dialect was unknown. The Spanish mission of Santa Barbara, and also that of Buena Ventura, are situated at a small distance from the canal of Santa Barbara. The shores of the bay or roadstead of Santa Barbara are for the most part low, and terminate in sandy beaches, with the exception of the western point, which is a steep cliff of moderate elevation, and which was denominated by Vancouver *Point Eclipse*. At Santa Barbara the latitude was $32^{\circ} 24'$, the variation $10^{\circ} 15'$ E. and the longitude $240^{\circ} 43'$. The tide regularly ebbed and flowed every six hours, its rise and fall being about three or four feet; and it is high water about eight hours after the moon passes the meridian. Vancouver's Voyage, vol. ii. p. 456.

BARBARA, in *Logic*, the first mode of the first figure of syllogisms.

A syllogism in barbara is that whereof all the propositions are universal and affirmative; the middle term being the sub-

ject in the first proposition, and attribute or predicate in the second.—For example:

“BAR Whoever suffers a man to starve, whom he ought to sustain, is a murderer:

BA Whoever is rich, and refuses to give alms, suffers those to starve whom he ought to sustain.

RA Therefore, whoever is rich, and refuses to give alms, is a murderer.”

BARBARATA *Islands*, in *Geography*, are situated three leagues west from the river Turiano; the bay of Trillo lies W. S. W. from them, on the Spanish main; and these islands are between the main and Venezuela, nearly west from the latter.

BARBARESQUE, in *Zoology*, the name given by Buffon to the Barbary squirrel; *sciurus getulus* of Schreber and Gmelin.

BARBARIA, in *Ancient Geography*, the name given in the Periplus of the Erythrean sea to the kingdom of Abyssinia, now called ADEL, the coast of which extends from the straits of Babelmandel to cape Gardesfan, about 457 geographical miles, and contains, according to the Periplus, four principal ports or anchorages, called by the general name of Tapera, the precise situation of which is not ascertained. Abalites was situated near the straits, Malao may be fixed at Delaqua, and Mundus at Zeyla; but the principal port was Mofillon, seated on a promontory, a whole degree north of Mundus; and this suits no other point on the coast but Barbara, a town on an island close to the shore, adjoining to a narrow cape of considerable extent.

BARBARIAN, in *Antiquity*, a name given by the ancient Greeks to all those who were not of their own country, or who did not speak the Greek language, or who did not speak it so well as themselves. In which sense the word signified with them no more than *foreigner*, and did not carry that odium with it which it does now. Strabo derives the word βαρβαρος; from βαρβαρίζω, *ballutire*, because foreigners coming to Athens used to stammer, or speak coarsely; others derive it from βαρβάρη, a word that foreigners frequently stumbled on, which yet had no meaning.

The Greeks had such an high opinion of the pre-eminence to which they were raised by civilization and science, that they seem hardly to have acknowledged the rest of mankind to be of the same species with themselves. To every other people they gave the degrading appellation of Barbarians; and, in consequence of their own boasted superiority, they asserted a right of dominion over them, in the same manner, to use their own expression, as the soul has over the body, and men have over irrational animals. Extravagant as this pretension may now appear, it found admission, to the disgrace of ancient philosophy, into all the schools. Aristotle, full of this opinion, in support of which he employs arguments more subtle than solid (Polit. i. c. 3—7.) advised Alexander to govern the Greeks like subjects, and the Barbarians as slaves; to consider the former as companions, and the latter as creatures of an inferior nature. But the sentiments of the pupil were more enlarged than those of his master; and his experience in governing men taught the monarch what the speculative science of the philosopher did not discover. See Plut. de Fortun. Alex. Orat. i. Strabo, lib. i. p. 116. A.

The Greeks gave the denomination of Barbarians in a peculiar manner, and with a contempt blended with animosity, to the Phrygians, on account of the enmity that had subsisted between them since the wars of Troy. This appears in the “Orestes” of Euripides, and in the scholia upon the “Ajax Maitigophorus” of Sophocles. The Ro-

maus alio, in imitation of the Greeks, called all other people, the Greeks excepted, barbarian; and the compliment was returned to them by the inhabitants of other nations. Thus Ovid, who was considered at Rome as a polished courtier, was treated in his exile as a barbarian by the Getæ, who did not understand his language, which was the idiom of Rome. *Tiſt.* l. v. el. 12. v. 37.

“Barbarus hic ego ſum; qui non intelligor ulli;
Et ridet ſolidi verba Latina Getæ.”

Under the lower empire, the appellation of barbarian became almoſt ſynonymous with that of ſtranger or foreigner. The Burgundians and Franks, who were eſtabliſhed in Gaul, were there called barbarians; and in Italy this name was given to the Goths. The term was alſo applied by the 52d canon of the African church to the inhabitants of thoſe provinces which had not ſubmitted to the Roman empire; and the denomination is frequently extended by Gregory of Tours, and alſo by other writers, to Pagans as contradistinguished from Chriſtians.

BARBARIANA, in *Ancient Geography*, a town of Spain, placed in the Anton. Itm. between Atiliana and Gracuris.

BARBARIC PHILOSOPHY, comprehends that of all ancient nations among whom the Greek language was not ſpoken. It has long been a ſubject of diſpute, whether philoſophy firſt appeared among the Barbarians or among the Greeks. The inhabitants of Greece, who were at an early period remarkable for literary and philoſophical vanity, and who ſoon acquired the uſe of an artificial method of philoſophizing, were unwilling to allow that philoſophy had any exiſtence in other countries, except where it had been borrowed from them. They could not perſuade themſelves, that the mere communication of precepts of wiſdom in the ſimple form of tradition, and in languages harſh and diſſonant compared with their own, could deſerve to be called philoſophizing. On the other hand, the barbaric nations in their turn treated the Greeks as barbarians, and looked upon them as children in philoſophy. Plato, in his *Timæus*, introduces a barbarian as inſtructing the wiſe Solon, and ſaying, “You Greeks are always children: there is not an old man amongſt you; you have no ſuch thing as grey-headed wiſdom.” In this perſuaſion they were the more confirmed, when they underſtood that the moſt learned men, and the moſt ancient philoſophers among the Greeks, had either been Barbarians by birth, or inſtructed by Barbarians (ſee *Clemen. Alex. Stromata*, l. i. p. 302, 303.); that Pythagoras, for example, was a Tuičan, Antilthenes a Phrygian, Orpheus a Thracian, Thales a Phœnician; and that Thales, Pythagoras, Plato, and others, had derived their knowledge from Chaldean and Egyptian prieſts. Many of the Chriſtian fathers eſpouſed, in this diſpute, the cauſe of the Barbarians, and maintained, with great vehemence, and with all the learning they could command, that the Barbaric philoſophy was the fountain of all the wiſdom which had appeared among the Greeks, except ſo far as they had been indebted, in the way of tradition, to divine revelation. This diſpute, however, was owing to the want of diſtinct ideas, and an accurate uſe of terms; and can in reality be conſidered as nothing more than a logomachy. For no one can aſſert that the barbaric nations were wholly inattentive to wiſdom, or ſtrangers to every kind of knowledge, human or divine; and, on the other ſide, it cannot be queſtioned, that they acquired their knowledge rather by ſimple reflection than by ſcientific inveſtigation, and that they transmitted it to poſterity rather by tradition than by demonſtration. Whereas the Greeks, as ſoon as they began to be civilized, diſcovered a general propenſity to inquiry, and adopted ſcientific rules and methods of reaſoning. Hence it is eaſy to

perceive, that though the improvement of philoſophy is to be aſcribed to the Greeks, its origin is to be ſought for among the Barbaric nations. Tatian, in *Proem. Clem. Alex. Strom.* l. i. p. 302. Origen adv. Celfum, l. i. Beaufobre *Hiſt. du Manich.* p. 2. l. i. c. 2. Scaliger *Exerc. ii. contra Cardan.* p. 183. Boſ *Animadv. ad Script. c. ii.* p. 12. Heuman. *Act. Phil. v. ii.* p. 204. Heurnii *Ant. Phil. Barb. ed. Lugd. Bat.* 1600.

The Barbaric philoſophy, in the moſt extenſive ſenſe of the term, and in its reference to the ſtate of philoſophy, from the earlieſt times to the decline of the Roman republic, comprehends that of the eaſtern nations, including the HEBREWS, CHALDEANS, PERSIANS, INDIANS, ARABIANS, and PHENICIANS; that of the ſouthern nations, or EGYPTIANS and ETHIOPIANS; that of the weſtern nations, to which we may refer the CELTS, the ETRURIANS, and the ROMANS; and that of the northern nations, including the northern SCYTHIANS, THRACIANS, GETÆ, &c. among whom Abaris, Anachariſis, Toxaris, and Zamolxiſis, obtained the praiſe of wiſdom. See *Brucker's Hiſt. of Philoſophy* by Enfield, vol. i. Introduction.

BARBARICA, in *Entomology*, a ſpecies of BUPRESTIS, found in Barbary. It is a ſmall inſect; colour above braſſy, beneath coppery; wing-caſes very entire and ſlightly ſtriated. Fabricius.

BARBARICA, a ſpecies of CHRYSOMELA, of a braſſy-green, with five red lines on the wing-caſes; wings ſanguineous. Inhabits Barbary. Sulzer. Gmelin.

BARBARICARII, in *Antiquity*, a kind of artiſts, who, with threads of divers colours, expreſſed the figures of men, animals, and other things; or, as others deſcribe them, thoſe whoſe buſineſs was to gild and decorate ſhields and helmets with gold and ſilver.

The barbaricarii were ſo called, becauſe they learned this kind of painting from the Phrygians, who were particularly denominated *barbarians*, in regard of their oppoſition to the Greeks; though the name is ſometimes alſo written *branbaricarii*.

BARBARICARII ſeem alſo to have been uſed for ſoldiers or officers, who wore maſks and vizards thus adorned with gold and ſilver.

BARBARICUM, in *Ancient Writers*, is uſed for a military ſhout, raiſed by the ſoldiers on point of engagement. This is called barbaricum from the barbarians, in whoſe armies this method of ſhouting much obtained. The ſame appellation was given to a war or expedition undertaken againſt the barbarians.—“*Quoſque ad ipſum tempus quo barbaricum extortum eſt inter nos & vos.*”

BARBARICUM was alſo uſed for an armoury, or magazine, wherein the Greek emperors kept the ſpoils and donaries taken from the barbarians in the time of war or peace.

BARBARICUM, in the *Materia Medica*, is alſo an appellation given by the modern Greeks to rhubarb. It is thus called from the *Sinus Barbaricus*, by the way of which this root was firſt brought to them.

BARBARICUS, in *Entomology*, a ſpecies of CIMEX (*Reduvius*), of a black colour; thorax and wing-caſes obſcure ferruginous, and a little white line on the middle of the ſcutellum. A native of Barbary. Gmelin.

BARBARICUS, in *Ornithology*, a ſpecies of RALLUS that inhabits Barbary. It is ferruginous, with a black bill; wings ſpotted with white; rump white, ſtreaked with black; white below; legs obſcure brown. Gmelin. This is the *Barbary rail* of Latham.

BARBARICUS, a ſpecies of TURDUS, of a green colour, with the breaſt ſpotted with white; rump and tip of the tail

tail yellow. Gmelin. This is the *Barbary thrush* of Latham, and *grive bassette de Barbarie* of Buffon. Inhabits Barbary; and is about the size of the missel thrush.

BARBARISM, in *Grammar*, denotes an offence against the purity of style or language.

A barbarism differs, according to Isidore, from a *barbarous term*, as the former, for instance, is Latin, though corrupt or misused; whereas the latter, which this writer calls *barborologia*, is a word merely foreign intruded into Latin speech.

In general, under barbarisms are comprehended things written, spoken, declined, or conjugated wrong; or used in a wrong quantity, or in an unusual sense; as when a word is used which is foreign to the language, and not received by the better and purer sort of writers therein. Such are *liper* for *liber*, *syllaba* for *syllaba*, *patri* for *patris*, *lexi* for *legi*, *bannus* for *proscriptio*, &c.

Barbarism is often charged, with great justice, on modern writers in the learned languages. The Latin books of late ages are full of Anglicisms, Gallicisms, Germanisms, &c. according to the country of the author. But what shall we say to Casp. Scioppius, who accuses Cicero himself of barbarisms in his own language?

There are great disputes among critics concerning barbarisms in the New Testament.

Divers pious persons are startled at the apprehension of any thing like a barbarism in the inspired books, as supposing it an objection to the inspiration of them; yet this does not hinder but many of the Jews, after Abarbanel and others, still maintain barbarisms in the Old Testament; in which they are seconded by M. Simon, Le Clerc, and others. The latter of these writings abound with Chaldaisms; and the books of Moses are not free from Egyptian words.

If we consider that among native Greeks a barbarous idiom could only mean such as was not conformable to the rules of their grammarians and rhetoricians, and to the practice of their writers of reputation, it may be conceded that the style of the New Testament is of this kind, without derogating from the character of the apostles and evangelists, without impeaching their inspiration, and without injuring the authenticity of their writings. This concession, the most learned and oratorical of the Greek fathers, as for instance Origen and Chrysostom, did not scruple to make; and, in such cases, it must be acknowledged that a native of common sense is a much better judge than any learned foreigner. Nevertheless many have contended that the Greek of the New Testament is as purely classical as that of the Attic writers, and they have even condemned as impious heretics those who have dared to dissent. It has been asserted, that the contrary implies an imperfection inconsistent with divine inspiration, and that men capable of such a doctrine were not only impious, but were guilty of the sin against the Holy Ghost. And yet this doctrine was maintained by Erasmus, Luther, Melancthon, Camerarius, Beza, Drusus, Casaubon, Glassius, Gataker, Solanus, Olearius, and Vorstius; though it has been denied by Pfochemus, Stolberg, Schmid, Georgi, and Blackwall. See *Erneski Institutio Interpretis N. T.* p. 41. ed. 3tia. Lipsiæ, 1775. But the advocates for this divine purity have not only betrayed their ignorance of the Greek language, but a high degree of pedantry in estimating the accuracy of language beyond its proper value. This last mistake has happened not only to the warm and partial friends, but likewise to the enemies of Christianity, who, from the time of Celsus to the 18th century, have maintained, that a book written in such language is neither divinely inspired, nor deserving attention and respect. Both parties have carried their zeal and their sentiments

to too great a length; and they would hardly consider an absolute purity of style, and a total absence of foreign words, of such importance as to make the contrary a crime, if they would condescend to quit the language of the schools for that of common life, or turn their attention from the language of the classics to those that are in common use. All foreign idioms, such as Hebraisms in Greek, Grecisms in Hebrew, or Latinisms in either, may be comprehended within the definition of barbarism, and sometimes even of solecism; but these words, it should be recollected, have always something relative in their signification; that turn of expression being a barbarism or solecism in one language, which is strictly proper in another, and to one class of hearers which is not so to another. The apostle Paul does not hesitate, by implication, to call every tongue barbarous to those who do not understand it. 1 Cor. xiv. 11. Nor does it make any difference, as appears from the whole of the apostle's argument, even if what is spoken be spoken by the spirit. With equal reason we may say of those foreign idioms in any tongue, which render what is said unintelligible or even obscure to the natives, that in respect of them they are barbarisms. Nor will any judicious person deny, that there are some idiomatical expressions in the New Testament, which must have puzzled those who were absolute strangers to the language of holy writ. Such idioms the writers of the New Testament would naturally adopt. They occurred in the Septuagint, which they were in the habit of using; and these would co-operate towards infecting their style with the tendency, which, as natives of Palestine, they would derive from conversation, to intermix Hebraisms and Chaldaisms in their writings. If we would enter thoroughly into the idiom of the New Testament, we must familiarize ourselves with that of the LXX; and if we would enter thoroughly into the idiom of the LXX, we must accustom ourselves to the study, not only of the original of the Old Testament, but of the dialect spoken in Palestine between the return of the Jews from the Babylonish captivity and the destruction of Jerusalem by the Romans; for this last, as well as the Hebrew, has affected the language both of the old Greek translation and of the New Testament.

Besides, it is proper to consider in relation to this subject, that vulgarisms and foreign idioms, which may obtain among strangers, and those of the lower ranks, have no more natural unsuitness to convey the sense which they that use them intend to convey by them, than the terms and phrases which, in consequence of the preference given by their superiors, may be regarded as elegancies. It may be as reasonably objected against our religion, that the persons by whom it was propagated were chosen from a class which men in high life account the dregs of the people, as that the Holy Spirit should accommodate himself to the language of those who were actually chosen. Nay, language as well as dress being in fact no more than a species of mode, it may with as good reason be maintained that the ambassadors whom Christ deputed to promulgate his doctrine, should have been habited like gentlemen and men of fashion, as that they should have spoken the dialect of such. Should it be asked, why did the Holy Spirit chuse to deliver such important truths in the barbarous idiom of a few obscure Galileans, and not in the polite and more harmonious strains of Grecian eloquence? The answer is obvious:—That it might appear beyond contradiction, that the excellency of the power was of God, and not of man. Moreover, the writings of the New Testament carry, in the very expression and idiom, an intrinsic and irresistible evidence of their authenticity. They are such as, in respect of style, could not have been written but

by Jews, and hardly even by Jews superior in rank and education to those whose names they bear; and the argument is strengthened by considering that under their homely garb we find the most exalted sentiments, the closest reasoning, the purest morality, and the foundest doctrine. In the discussion of this subject, we should likewise consider the situation and character of the persons for whose use the New Testament was more immediately written. They were partly either native Jews, or pious persons who were proselytes to the doctrine of Moses, and who, by continual intercourse with native Jews, and the constant reading of the LXX, were accustomed to Jewish Greek. It is highly probable, therefore, that if the New Testament had been written with Attic purity, it would have been unintelligible to many of its earliest readers, who had never read the doctrines of religion in any other dialect than Jewish Greek. We shall only observe further in this place, that a classical or unclassical style has no more influence on the divinity of the New Testament, than the elegance or inelegance of the hand in which it is written, and the accuracy or inaccuracy of the pronunciation with which it is uttered. Whoever is accustomed to write a bad hand would certainly not improve it by inspiration; but admitting the fact, it would have this unfortunate consequence, that no one accustomed to the hand would in its improved state believe it to be genuine. There is no reason to believe, that inspiration would amend a faulty pronunciation; and the writers of the different parts of the Bible have undoubtedly spoken in the same manner, both before and after the effusions of the Holy Ghost. If these failings then are consistent with supernatural endowments, "I can see no reason," says Michaelis, "for drawing an argument against the divinity of the New Testament from its vulgarisms, or even from its grammatical errors." A particular account of the writings of those authors, who have engaged in the controversy relating to the purity of the language of the New Testament, may be seen in Walchii Bibliotheca Theologica, t. iv. p. 276—289. See also Fabr. Bib. Græc. t. iv. p. 224—227. Michaelis's Introd. to the New Testament by Marsh, vol. i. ch. 4. § 4. p. 116, &c. Campbell on the Four Gospels. Prelimin. Diss. vol. i. p. 13, &c. See more on this subject under the articles INSPIRATION, and *Language of the New Testament*.

BARBARISM, *Barbaries*, is also used for that rudeness of mind, wherein the understanding is neither furnished with useful principles, nor the will with good inclinations.

BARBARISSOS, in *Ancient Geography*, a town of Asia, in Syria, in the Chalybonitide country. Ptolemy.

BARBARIUM *Promontorium*, a promontory of Lusitania, placed by Ptolemy south of the city of Olios-Hippon, or Oliosipon, Olesipo, or Lisbon, in 39° 45' N. latitude.

BARBARO, FRANCIS, in *Biography*, a noble and learned Venetian, was born in 1398, and distinguished by his love of literature, and his talents for public business. Under the learned Grecian Chrysoloras, he acquired that profound knowledge both of the Greek and Latin languages, of which he gave specimens in his translations of Plutarch's lives, of Aristides, and Cato, and in his elegant moral work, written in Latin, intitled "De Re Uxoriam," and first published without his name, in 4to. at Paris, in 1515. This work furnishes useful instructions with regard to the choice of a wife, and the duties of wives and mothers. He was also the author of some orations and letters, which manifest good taste and an amiable temper. In all the public offices which Barbaro sustained, he displayed eminent virtues. Whilst he was governor of Brescia, he had occasion for the exercise both of courage and discretion. The

city was divided into two violent factions, which he prevailed upon to unite, and to act in concert for the public good; and though at the same time it was besieged by the Milanese forces under the great commander Piccinino, and suffered much by famine and disease, he at length, after a protracted siege of three years, obliged the enemy to retire. He died much regretted by his countrymen, in 1454, at the age of fifty-six years. His letters were collected and printed at Brescia in 1743. Gen. Dict.

BARBARO, *Hermolao*, the elder, was the nephew of the preceding, and distinguished by his early acquaintance with the Greek language, inasmuch that at twelve years of age he translated many of AEsop's fables into Latin. He was advanced, at the age of thirty years, by pope Eugenius, to the episcopal see of Treviso; and ten years afterwards he was translated to that of Verona, where he died in 1470, aged sixty years. He left translations of Greek authors.

BARBARO, *Hermolao*, or *Hermolao Barbarus*, the younger, was the grandson of Francis Barbaro, and born at Venice, in the year 1454. In very early life he was eminently distinguished by his genius, application, and proficiency; and at the age of fourteen years he received from the hand of the emperor Frederic the poetic crown. At sixteen, he undertook the translation of Themistius, which was published seven years afterwards. Having graduated in the school of Padua in jurisprudence and philosophy, he returned to Venice, and devoted himself entirely to affairs of state. However, after an interval of twelve years, he resumed his studies with fresh ardour; and, particularly attached to the Greek language, he read lectures, without gratuity, in his own house, upon Demosthenes, Theocritus, and Aristotle, which were very numerously attended. At the age of thirty-two years, he was sent ambassador to the emperor Frederic, who conferred upon him the honour of knighthood; and in consequence of a subsequent embassy to pope Innocent VIII. that pontiff created him patriarch of Aquileia. This office he accepted, though the laws of Venice had prohibited its ministers from accepting any dignity from any foreign prince, without the consent of the republic; and for his opposition to this order, the Venetians pronounced upon him a sentence of perpetual exile. For preventing its execution he wished to relinquish the patriarchate; but the pope refused to accept the renunciation. From this time, he resided at Rome; but upon the access of the plague, he removed into the country, which, however, afforded him no asylum; for he was seized with this malady, and died in the year 1493.

Besides the translation of Themistius, Hermolao published versions of Dioscorides, and of the rhetoric of Aristotle; an abridgement of the moral and physical doctrine of that philosopher; two large works upon Pliny, one intitled "Constitutiones Plinianæ," the other "Constitutiones Secundæ;" "Corrections of Pomponius Mela;" and an "Explanation of the more difficult words in Pliny." He boasted that he had corrected 5000 errors in the text of Pliny, and 300 in that of Mela. Although he is charged with having been too free in his conjectural emendations, he exercised great ingenuity and industry in these labours. The illustrious Lorenzo de' Medici treated him with great respect, and when he was at Florence on an embassy from the republic of Venice, entertained him very liberally and offered him the use of his villa and library for the prosecution of his studies. "Hermolao is certainly entitled to rank in the first class of learned men, at a period when classical learning was the first and almost the sole object of attention: nor is it any depreciation of his merit as a scholar, whatever it may be of his character as a philosopher,

pher, if the whimsical story be true, that, being exceedingly perplexed concerning the meaning of Aristotle's *ἑίδεσθαι*, a term which has perhaps never been understood, he endeavoured, or pretended to consult the devil upon the subject." Gesner in Bibliothec. Gen. Dict.

BARBAROSSA, so called from the red colour of their beard, Arac or Horuc, and Hayradin, were the sons of a potter of the island of Lesbos, or as some say, of a Sicilian renegado; who, prompted by a restless and enterprising spirit, forsook their father's trade, and joined a crew of pirates. They soon distinguished themselves by their valour and activity, and becoming masters of a small brigantine, carried on their infamous trade with such conduct and success, that they assembled a fleet of twelve galleys, besides many vessels of smaller force. Of this fleet, Horuc, the elder brother, was admiral, and Hayradin second in command, but with almost equal authority. They called themselves the friends of the sea, and the enemies of all who sail upon it; and their names soon became terrible from the straits of the Dardanelis to those of Gibraltar. Whilst they were acting as corsairs, they adopted the ideas and acquired the talents of conquerors. They often carried the prizes which they took on the coasts of Spain and Italy, to which they extended their depredations about the year 1504, into the ports of Barbary; and enriching the inhabitants by the sale of their booty, and the thoughtless prodigality of their crews, they were welcome guests in every place at which they touched. The convenient situation of these harbours, lying to near the greatest commercial states at that time in Christendom, made the brothers wish for an establishment in that country. An opportunity occurred for this purpose, which they eagerly seized and improved to their own advantage. Eutemi, king of Algiers, having made several unsuccessful attempts for taking a fort which the Spanish governors of Oran had built not far from his capital, fought the assistance of Horuc, whose valour the Africans considered as irresistible. The active corsair gladly accepted the invitation, and leaving his brother Hayradin with the fleet, marched at the head of 5000 men to Algiers, where, in the year 1516, he was received as their deliverer. Such a force gave him the command of the town. The ambitious conqueror, having secretly murdered the monarch whom he came to assist, caused himself to be proclaimed king of Algiers in his stead. He then proceeded to establish the authority which he had usurped, by arts suited to the genius of the people whom he had to govern; by unbounded liberality to those who favoured his promotion; and by cruelty as unbounded towards all whom he had any reason to distrust. Having detected and defeated a conspiracy formed against him by the Arabs, and obliged the king of Tunis, who marched to their succour with a powerful army into the territory of Algiers, to seek refuge in the mountains; Barbarossa laid siege to Tunis, made himself master of it, and was acknowledged as sovereign. He then attacked the neighbouring king of Tremeccen, vanquished him in battle, and added his dominions to those of Algiers. At the same time he continued his depredations on the coast of Spain and Italy; and the devastations which he committed obliged Charles V., at the beginning of his reign, to furnish the marquis de Comares, governor of Oran, with troops sufficient to attack him. That officer, assisted by the dethroned king of Tremeccen, executed the commission with such spirit and success, that Barbarossa's troops being defeated in several encounters, he himself was shut up in the citadel of Tremeccen. After defending it to

the last extremity, he was reduced by the apprehensions of famine to the necessity of attempting an escape by a subterraneous passage; and in order to delay the pursuit, he scattered his treasures upon the road. At length the Spaniards overtook him on the banks of the Huedra, eight leagues from Tremeccen; and here Barbarossa with his Turkish followers fought for some time with an obstinate valour, but they were at last totally defeated, and the conqueror himself was slain, in the forty-fourth year of his age, A.D. 1518.

His brother Hayradin, known likewise by the name of Barbarossa, assumed the sceptre of Algiers with the same ambition and abilities, but with better fortune. His reign being undisturbed by the Spaniards, who were fully employed in the wars among the European powers, he regulated with admirable prudence the interior police of his kingdom, carried on his naval operations with great vigour, and extended his conquests on the continent of Africa. For his greater security, he put his dominions under the protection of the Grand Signior, and received from him a body of Turkish soldiers sufficient for his defence against domestic as well as foreign enemies. Soliman at length A.D. 1533, offered him the command of the Turkish fleet, in opposition to Andrew Doria, who was the greatest sea-officer of that age. Barbarossa, proud of this distinction, repaired to Constantinople, and with a wonderful versatility of mind, combined the address of a courtier with the boldness of a corsair, and thus gained the entire confidence of the sultan and his vizier. To them he communicated a scheme which he had formed of making himself master of Tunis, the most flourishing kingdom, at that time, on the coast of Africa; and as they approved the scheme, they furnished him with every thing he demanded for carrying it into execution. Availing himself of the intestine divisions of the kingdom, and making perfidious use of the name and interest of Abraschid, an exiled prince, whom he deceived and imprisoned, he was supported by a powerful fleet and a numerous army. His fleet consisted of 250 vessels, with which he sailed towards Africa; and after ravaging the coasts of Italy, he appeared before Tunis. Having landed his men, he announced his intention of asserting the right of Abraschid, whom he pretended to have left sick on board of the admiral gally, but who was in reality confined in the seraglio at Constantinople, and who was never heard of more. The fort of Goletta, which guards the bay, soon submitted, and the inhabitants of Tunis declared unanimously in favour of Abraschid; so that the gates were opened to Barbarossa, whom they considered as the restorer of their lawful sovereign. But as Abraschid did not appear, they soon began to suspect the corsair's treachery; and with arms in their hands, surrounded the citadel into which Barbarossa had led his troops. Their attack, however ardent and impetuous, was of no avail; and they were forced to acknowledge Solyman as their sovereign, and to submit to himself as his viceroy. Having put the kingdom into a proper posture of defence, he extended his depredations to the Christian states, so that complaints of his outrages were conveyed to the emperor Charles by his subjects both in Spain and Italy. The emperor concluded a treaty with Muley-Hascen, the exiled king of Tunis, who implored his assistance; and made preparations for invading Tunis. His fleet consisted of nearly 500 vessels, and they had on board above 30,000 regular troops. The armament sailed from Cagliari, and after a prosperous navigation, landed within sight of Tunis. Barbarossa assembled at Tunis for opposing the imperial

army, a force composed of 20,000 horse, together with a vast body of foot. By the reduction of the Goletta, after an obstinate defence by 6000 Turkish soldiers under the command of Sinan, a renegade Jew, the bravest and most experienced of all Barbarossa's corsairs, the emperor became master of the fleet, consisting of eighty seven galleys and galliots, together with the arsenal, and 300 cannon mostly of brass, that were planted on the ramparts. In these circumstances, however, Barbarossa neither lost his courage, nor abandoned the defence of Tunis. But as the walls were extremely weak as well as extensive, he determined to advance with his army, amounting to 50,000 men, towards the imperial camp, and to decide the fate of his kingdom by the issue of a battle. Having communicated his resolution to his principal officers, he proposed to provide against the danger of a mutiny among the Christian slaves, during the absence of the army, by massacring 10,000 of them before he began his march. The barbarity of the proposal filled his officers with horror; and Barbarossa, dreading their resentment, consented to spare the lives of the slaves. The emperor's army which suffered inconceivable hardships in their march over burning sands, soon came up with the Moors and Arabs under the command of Barbarossa, who were so completely routed, that, notwithstanding all his efforts to rally them, he was hurried along with them in their flight back to the city. This was found a scene of confusion; some of the inhabitants were flying with their families and effects; others were opening the gates to the conquerors; the Turkish soldiers were retreating; and the citadel was in possession of the Christian slaves. Barbarossa, disappointed and enraged, fled precipitately to Bona; and Tunis surrendered to the victorious army of the emperor. But the lustre of this victory was tarnished by the excesses of the soldiers; who sacrificed more than 30,000 of the innocent inhabitants, and carried away 10,000 of them as slaves. Barbarossa escaped first to Algiers, and then repaired to Constantinople, where he was received again into favour, and sent with a fleet to ravage Calabria. Having persuaded Solyman to make war on the Venetians, he committed great devastations in the isle of Corfu, and afterwards made an expedition to the coast of Arabia Felix, when he reduced all Yemen under the Turkish dominion. In a subsequent war between the Turks and Venetians, he took many islands in the Archipelago. In 1538 he crossed over to Candia, and made an unsuccessful attempt on Canea. From thence he retired to the Ambracian gulf, where he was overtaken by the Christian fleet under the famous Andrew Doria. By his skilful manœuvres he not only avoided the danger that threatened him, but gained some partial advantages, and caused Doria to make a hasty retreat to Corfu. In 1539 he recovered Castel Nuovo from the confederates. In 1543, Barbarossa left Constantinople with a powerful fleet; and proceeding to the Faro of Messina, took Reggio, and sacked the coast of Italy. He then besieged and took Nice; but when Doria approached with his fleet, Barbarossa avoided him; and remaining in those seas during winter, he next spring ravaged the coasts and islands of Italy, and then returned with many prisoners to Constantinople. During the remaining period of his life, he superintended the naval affairs of the grand signior, and pursued that voluptuous course to which he had been habituated, amidst a number of fair captives; and died at the age of eighty years, in 1547, leaving his son Hassan in possession of the vicerealty of Algiers, and heir to all his property. With the ferocity of a Turk and a corsair, Barbarossa possessed some generous

sentiments, and obtained a character for honour and fidelity to his engagements. Mod. Un. Hist. vol. x. p. 66, &c. vol. xv. p. 14, &c. Robertson's Hist. of Charles V. vol. iii. p. 97, &c. Gen. Biog. See ALGIERS.

BARBAROSSA, in *Entomology*, a species of SCARABÆUS, described by Fabricius as a native of New Holland. The anterior part of the thorax is scabrous; horns of the head recurved and short.

BARBAROUS, in a general sense, denotes something that partakes of the quality of BARBARISM; and in this sense, the term is applied to a nation, age, writer, word, or the like. Barbarous Latin words are innumerable; the schoolmen abound with them; the chemists, physicians, and lawyers can scarcely write intelligibly without them. Du-Cange has given two large volumes in folio of barbarous Latin words, and as many of Barbarous Greek words. The modern or vulgar Greek is sometimes called barbarous Greek, "barbaro-Greca," or "Greco-barbara lingua." Langius has published "Philologia Barbaro-Greca," "Grammatica Barbaro-Greca," or "Glossarium Barbaro-Grecum."

BARBARUS, in *Entomology*, a species of Papilio. (*Pleb. Rur.*) The wings are without tails, and blueish; beneath spotted all over with brown, and two spots behind. Gmelin.

BARBARUS, a species of TENEBRIO, of a black colour, and very glossy; thorax orbiculated; anterior margin of the shield of the head elevated. This is about the middle size; wing-cases joined. Brander, &c.

BARBARUS, a species of CRYPTOCEPHALUS that inhabits Barbary. The antennæ are ferrated; body hairy, obscure, bristly. Found on composite flowers. Fabricius.

BARBARUS, in *Ichthyology*, a species of SYNGNATHUS, found in European seas. It has neither caudal nor anal fin; body six-sided. Gmelin. In the dorsal fin are about forty-three rays; and in the pectoral fin twelve rays; body olive with faint blueish transverse lines.

BARBARUS, in *Ornithology*, a species of VULTUR that inhabits Barbary, and some other parts of Africa. It is of a blackish brown; beneath white, inclining to brown; legs woolly; toes lead colour; claws brown. Gmelin. This is *vultur barbatus*, Briss. Orn. and *bearded vulture* of Edwards and Latham.

BARBARUS, a species of FALCO, called by the English writers the *Barbary falcon*; the cere and legs are yellowish; body blueish, spotted with brown; breast immaculate; tail banded. Gmelin. The length of the bird is seventeen inches, and, as its name implies, it is a native of Barbary.

BARBARY, in *Geography*, the northern tract of Africa, is one of the three distinct parts of North Africa, according to the distribution of major Rennel, and lying along the Mediterranean. See AFRICA.

As to the origin of the name of Barbary, we have a variety of conjectures. Some suppose, that the Romans, after they had conquered this large tract, gave it the name by way of contempt or dislike of the rude and barbarous manners of the natives. Marmol deduces it from the Arabic word "Berber," a name given by the Arabs to the ancient inhabitants, and which they retain to this day in many parts of this tract, especially along the ridge of the Great Atlas, where they are very numerous, and which was given to them by their new invaders on account of the barrenness of their country. Leo Africanus says that it was given to these people on account of their strange language, which appeared to them an inarticulate murmur, the Arabic word "barbar," signifying "a murmuring sound or noise."

Others

Others derive it from "bar" twice repeated, which signifies a "desert," which was its ancient state; accordingly, they say that the fugitive king Ifrik, from whom it is pretended the whole African continent derived its name, when closely pursued by his enemies in his flight out of Arabia Felix, and hesitating what course to pursue, was directed by some of his retinue by these words, "Bar, Bar," that is "To the Desert, To the Desert."

The history of the word "Barbar," says Gibbon (Rom. Emp. vol. ix. p. 463.), may be classed under four periods. 1. In the time of Homer, when the Greeks and Asiatics might probably use a common idiom, the imitative found "of Bar-bar," was applied to the ruder tribes, whose pronunciation was most harsh, whose grammar was most defective. *Κατὰ Βαρβαρῶν* (Iliad. ii. 867. with the Oxford Scholiast, Clarke's Annotation, and Henry Stephens's Greek Thesaurus, tom. i. p. 720.) 2. From the time, at least, of Herodotus, it was extended to all the nations who were strangers to the language and manners of the Greeks. 3. In the age of Plautus, the Romans submitted to the insult (Pompeius Festus, l. ii. p. 48. ed. Dacier), and freely gave themselves the name of Barbarians. They insensibly claimed an exemption for Italy, and her subject provinces, and at length removed the disgraceful appellation to the savage or hostile nations beyond the pale of the empire. 4. In every sense, it was due to the Moors; the familiar word was borrowed from the Latin provincials by the Arabian conquerors, and has justly settled as a local denomination (Barbary) along the northern coast of Africa.

Barbary is bounded on the north by the Mediterranean sea, which divides it from Europe, on the east by Egypt, on the south by Sahara, Zaara, or the Desert, and on the west by the Atlantic ocean. Its utmost extent from east to west, that is, from cape Non, on the most western coast of Morocco, to the confines of Egypt, is almost 37 degrees, that is from 10° W. to 26½ E. long. or about 2200 geographical miles. Its breadth from north to south is very unequal; in some parts it is not above 6 or 7 degrees; and where it is widest, as from cape Non to Tangier, not above 10 degrees. Some geographers, however, have given it a much greater extent both in length and breadth, making the former 4000 miles, and the latter 1200, in order to which estimate they have included the creeks and windings, which are too precarious and unknown to be depended upon. Others have made the length from east to west to be only 1200 miles, and the breadth from north to south, which is very variable, 320 miles. It commences on the west at the famous mount Atlas, called by the Arabs Ayduacal, or Al Duacal, and incloses the ancient kingdoms of Suez and Dela, now provinces of Morocco, and extends north-eastward along the Atlantic coast to the pillars of Hercules at cape Finisterre, through the straits of Gibraltar, and so on by an eastern course, along the Mediterranean coast to the city of Alexandria, which is the southern boundary of Egypt, where it joins to this of Barbary. The principal kingdoms into which it is now divided, are those of Morocco, Fez, Algiers, Tunis, and Tripoli; the kingdom of Telenin or Tremecen having been incorporated with that of Algiers, and that of Barca having been reduced to a dependence on that of Tripoli. (See each of these articles.) Both the coasts of Barbary, whether watered by the Atlantic ocean, or by the Mediterranean, are fertile in corn and paskurage; the former being watered by a multitude of small and large rivers which descend from the great Atlas, and empty themselves into the ocean; and the former extending along the declivity of a vast ridge of mountains, some of which are considerably high, and spread above

40 leagues into the inland, supplying a number of rivers, which after many windings through pleasant and fertile valleys, discharge themselves into the Mediterranean. Besides, the temperature of the climate contributes to its fertility. However the coast and mountains along the Mediterranean from the straits of Gibraltar to Egypt, are rather cold than hot, and snow falls at certain times of the year; and the tops of some mountains are covered with it through the year. The winter in this country commences about the middle of October, and is often severe; the rains commonly begin about the end of the month, and continue to the end of January; in February the weather becomes milder; and in March the west and north winds begin to blow and to produce universal verdure. During the whole spring season, which begins about the latter end of February, the weather is generally serene and pleasant, except from the latter end of April to that of May, when refreshing showers are abundant; which with the concurring heat of the sun, bring the productions of the earth to maturity; so that in the latter end of May, they begin to gather ripe figs and cherries in Tunis, Algiers, and some parts of Morocco: in the middle of July, the apples, pears, and plums are ripe, and grapes and other later fruits are completely gathered before the latter end of September. The summer begins, according to their reckoning, on the 28th of May, and lasts till the 29th of August; during which the heats are excessive and dangerous; their autumn commences on the 27th of August, and ends on the 16th of November, when the heat abates; and their winter begins on the 17th of November, and ends on the 16th of February. The greatest cold begins on or about the 12th of December, and the greatest heat about the 12th of June. On mount Atlas, and the higher lands, they reckon but two seasons, namely, winter and summer; the former lasting from October to April, when great quantities of snow fall, and the latter from April to September, when the heat in the valleys is excessive.

The principal quadrupeds of the states of Barbary are the horse, which has of late years very much degenerated, the ass and mule, the kumrah, produced between an ass and a cow, the camel, the black cattle, which are small and slender, the goat, and sheep, of which latter there are two species not known in Europe; the one the broad-tailed sheep, and the other the sheep of Sahara, as tall as our fallow-deer, and resembling them in shape. Each of these kinds of quadrupeds is very numerous and prolific. Several Arabian tribes, who can bring no more than three or 400 horses into the field, are possessed of more than 50 many thousand camels, and triple the number of sheep and black cattle. The Arabs seldom diminish their flocks by using them for food, but live chiefly upon bread, milk, butter, dates, or what they receive in exchange for their wool. Among the quadrupeds that are not naturally tame and domesticated, we may reckon the "bekker-el-wash," or wild cattle, which Dr. Shaw supposes to be the bubalus of the ancients, or bos Africanus of Bellonius; and deer, in size betwixt the red and fallow-deer; the fistall or serwee, seeming in size, shape, and other circumstances, to be the tragelaphus of the ancients, or an animal betwixt a goat and a deer; the gazell or antelope, of which there is a species called hidmea, supposed by Shaw to be the strepsiceros or addace of the ancients. Among quadrupeds of a less tameable nature, we may enumerate the lion and panther; the saadh or charius of Pliny, the lesser panther, and the shibeardou or Spanish ginetta; the dublah or hyena; the deeb or jackall; the siyah-gush or black-eared cat; the porcupine; the jird, and jerboa. Besides these animals, Barbary also produces the bear or dakh; the ape or shaddy; the

ichneumon or teordea; the ferret or nimfe; and the weasel or fert-el-hcile. The mole, likewise, the rabbit, the hare, and the wild boar, which is the chief prey and food of the lions, are every where numerous. Among the oviparous quadrupeds, Dr. Shaw enumerates the land and water tortoise, the former being very palatable food, but the latter unwholfome; the warril or guaral; the dhab or dab; the zermoumeah; the skink or feincus; and the neije-laimah or booka-shrah. Of the serpentine kind, besides the flow-worm and the snake, which are common, the most remarkable species are the thalbanne, the zurrike or jaculus, the lessah or dipfas. These are the only species of the viper kind which Dr. Shaw discovered; and he adds, that the northern parts of Africa do not produce above five or six distinct species among the many that are described by Lucan and Nicander. Among the birds, he enumerates, besides the eagle kind, the karaburno, about the size of our buzzard, the red-legged crow or pyralo corn; the canefcy or ox bird; the boo-onk or long-neck; the buron-rou, one of the larger species of the horned-owl; the yarourou; the singlar; the houbarra or houbaary; the roud or fal-fal; the kitawiah or African lagopus; the Barbary partridge or red-legged quail; the green thrush; and the Capfa sparrow. The insects of this part of Africa are more numerous than curious. The most curious species of the butterfly kind is the lappet butterfly, about four inches from one tip of the wing to the other, beautifully streaked with murrey and yellow, and having near the tail a spot of a caration colour. The rarest species of the libellæ or adderbolts is one, $3\frac{1}{2}$ inches long, broad-tailed, of a rusty colour, with bright spotted wings. The least frequent of the beetle kind, is a species with one horn, of the colour and size of a chestnut. In the hotter months of the summer, the cicade, *cicada* ♀, or grasshopper, as we falsely translate it, is perpetually humming the ears with its shrill and ungrateful noise, from mid-day to the middle of the afternoon. The locusts are very numerous, first appearing towards the latter end of March, and in the middle of April forming large swarms, which even darken the sun, and beginning gradually to disappear in May. Of the ackrab or scorpion there are several species. For other particulars relating to the productions, commerce, customs, &c. of the states of Barbary, see ALGIERS, MOROCCO, &c.

The coast of Barbary was probably first planted by the Egyptians. The Phœnicians afterwards sent colonies thither, and built Utica and Carthage. The Carthaginians soon became powerful and wealthy by trade; and finding the country divided into many little kingdoms and states, either subdued or made the princes on that coast their tributaries, who, being weary of their yoke, availed themselves of the opportunity of assisting the Romans in subduing Carthage. The Romans remained sovereigns of the coast of Barbary, which indeed was almost the whole of their possession, Egypt excepted, on the continent of Africa, until the Vandals in the fifth century reduced it under their dominion. The Roman, or rather the Grecian emperors, having some time after recovered the coast of Barbary from the Vandals, retained the dominion of it till the Saracen caliphs made an entire conquest of the north of Africa in the seventh century, and divided the country among their chiefs, of whom the sovereign of Morocco was the most considerable, possessing the north-west part of that country, which, in the Roman division, obtained the name of Mauritania Tingitania, from Tingis or Tangier the capital; and is now stiled the empire of Morocco, comprehending the kingdoms or provinces of Fez and Morocco. In the eighth century, their ancestors made a conquest of the greatest part of Spain; but after the loss of Granada, about the year 1492, they were dispossessed of this

country, and compelled by Ferdinand and Isabella to renounce their religion, or transport themselves to the coast of Africa. The exiles confederated with the Mahometan princes on the coast of Barbary, and fitted out little fleets of cruizers, which made depredations on Spain, brought away many of its inhabitants, and made slaves of them. The Spaniards assembled a fleet of men of war, invaded Barbary, took Oran and other places on the coast of Algiers, and were proceeding to make an entire conquest of the country. In this distress, the African princes brought the assistance of the famous Turkish rover, called Barbarossa (see the article BARBAROSSA), against the Christians. When he had repulsed their enemies, he usurped the government of Algiers, and treated the people who called him to their succour as slaves. His brother Hayradin pursued the same measures with regard to the people of Tunis; and a third by similar means obtained the government of Tripoli. In these usurpations they were supported by the grand signior, who claimed the sovereignty of the whole coast, and for some time they were considered as the subjects of Turkey, and governed by Turkish bashas and viceroys; but each of these states, or rather the military men, at length elected a sovereign out of their own body, and rendered themselves independent of the Turkish empire. The grand signior has not now so much as a basha or officer at Algiers; but the dey acts as an absolute prince, and is only liable to be deposed by the soldiery that advanced him. At Tunis and Tripoli he has still bashas, who are some check upon the deys, and receive a small tribute. All of them, however, in case of emergency, claim the protection of the Ottoman court, and they still continue to prey upon the Spaniards, having never been at peace with them since the loss of Granada. They make prize also of all other Christian ships that have Spanish goods or passengers on board, and indeed of all others that are not at peace with them. The Turks of Algiers, Tunis, and Tripoli, are an abandoned race, consisting of pirates, banditti, and the refuse of Turkey, who have been forced to leave their several countries to avoid the punishment of their crimes. See ALGIERS, &c. and also AFRICA.

Barbary is chiefly inhabited by three sorts of people; namely, Moors, who are the original natives; the Arabs, who have overrun this country; and the Turks, who have since made themselves masters of some of its best provinces, and the several kingdoms of Tripoli, Tunis, and Algiers, though under a kind of tribute to, or dependence upon the Ottoman porte. The Moors, or natives, are for the most part Mahometans; as there are few who have not been induced or compelled to embrace Mahometanism since their subjection to the Turks. They are even more scrupulous observers of the Mahometan law than the Turks themselves; and as they are generally even more ignorant, they have adopted every absurdity of superstition. Among the customs of Barbary, no charm, or magic spell, no expedient, though ever so senseless, monstrous, and seemingly diabolical, can be invented, to which they will not have recourse, preferably to any of a more rational nature and efficacy, in fights, storms, or other emergencies attending their hazardous profession. Their condition is abject and miserable to the extreme, being crushed with a heavy load of taxes, and treated with the utmost cruelty by their insulting masters, or exposed to the continual inroads of the plundering Arabs. Such is the state of those who live at large in the country upon their agriculture and cattle. As for those who inhabit the sea-ports along the coast, they are allowed to follow a variety of handicraft trades and manufactures, and even to carry on some commerce by land and sea. But they are no less oppressed with taxes and other exactions. The

The Arabs of Barbary are like those of other parts of Africa; they follow the same mode of living, are governed by their own despotic cheyks, and all of them, except those of the wandering kind, and such as live under the dominion of the emperors of Morocco and Fez, are in some sort tributary to the Turks, ever since they have made themselves masters of the remainder of the Barbary coast. They are often obliged, by the oppression they suffer, to abandon their habitations, and to seek shelter among the most rocky and inaccessible mountains, whether the Turkish forces cannot pursue them. Such is the condition of those who live in the country, and along the ridge of mount Atlas; but there is another and more civilized class of them, who are, like the Moors, settled in some of the towns and villages, and apply themselves to agriculture, and especially to the breeding of that race of horses so much esteemed, known to us by the name of barbs, for which their country has been famous all over Europe. The wild, or wandering Arabs, who range along the great Atlas and other parts of Barbary, are warlike, bold, and even desperate in all their plundering excursions; especially in their attempts on the large and rich caravans, which go from Morocco into Egypt. The Arabs of each class are addicted to the study of astronomy and astrology, to which they are disposed by their pastoral life, which affords much leisure, their clear sky, and natural superstition. The neither sow, reap, plant, travel, buy, or sell, nor undertake any expedition, without previously consulting the stars, or in other words, their almanacks, or some of the makers of them, whether they be Mahometans or idolaters.

The Turks are of all the inhabitants of Barbary the fewest in number, and in all respects the worst of all the three classes; being originally no better than a wretched crew of indigent, loose, idle, and thievish fellows, invited in and about Constantinople, and sent from thence once in three years to recruit the soldiery. They are wanton and savage in the exercise of their tyranny over both the Moors and Arabs. They make ostentatious professions of Mahometanism; but in practice they neglect and violate its precepts in the most licentious degree, and are so notorious for the dissoluteness of their manners, that they are abhorred by all true Mahometans.

The whole tract of Barbary from one end to the other is so excellently situated for navigation and commerce, so fertile of every necessary of life in its variety of soils and climates, so rich in its mines of gold, silver, and other metals and minerals, so healthy, and so populous, that it might defy the whole force of Europe or Asia to reduce it, were its inhabitants as industrious as they are indolent and knavish, and were the several nations that inhabit it, or the several powers to which it is subjected, united in one common interest. Shaw's Travels, passim. Mod. Un. Hist. vol. xi. p. 226, &c. vol. xiv. p. 288. vol. xxxvii. p. 186, &c.

BARBARY Point, the western point of the entrance into the river, &c. of Senegal, on the coast of Africa. N. lat. $15^{\circ} 38'$. W. long. $15^{\circ} 30'$.

BARBAS, CAPE, lies on the coast of Africa, west from Cypriano river, and 26 leagues north from cape Blanco. N. lat. $22^{\circ} 15' 30''$. W. long. $16^{\circ} 40''$.

BARBASOTE, a sea-port town of Africa, in the kingdom of Fez, a little to the west of Ceuta.

BARBASTELLUS, VESPERTILIO, in *Zoology*, the tailed bat, with elevated hairy cheeks, and large ears, angulated on the lower part. (Linn. Syst. Nat. Gmelin, p. 48.) *Barbastelle* of Buffon and Pennant. Its length is about two inches from nose to tail; extent about ten inches; upper part of the body dusky brown; under part ash coloured;

for head sick; ears broad and long, lower parts of the inner sides touching each other, and thus concealing the face and head when viewed in front; nose short; cheeks full; end of the nose flattened; found in France. Shaw.

BARBATA, in *Entomology*, a species of *CANTHARIS* that inhabits Germany. It is of a brown colour; antennae and flanks pithy. Olivier. The down on the body is changeable to a golden hue.

BARBATA, a species of *CICADA* (*D. flava*) of a brown colour, with greenish abdomen, and a snowy-white woolly tuft at the vent. Fabricius, Gmelin.

BARBATA, a species of *PHALÆNA* that inhabits Barbary. The wings are greyish, with a brown spot in the middle, and an obsolete band below. Fabricius, &c.

BARBATA, a species of *PIMELIA* (*Halps* Fabr.) of a black colour; feelers advanced, and with the legs yellowish. Inhabits Saxony. Fabricius.

BARBATA, in *Natural History*, a species of *CORALLINA*, about three inches in length, that grows on the shores of Jamaica. Ellis, in his work on coralline, calls it the rosary or bead-coralline of Jamaica; it is the bead-band string of Plunket, and corallina major, nervo crassiori fuciformi intermedia breviora necente of Sloane. (Hist. Jam.) This kind is specifically distinguished according to Pallas, Solander, and others, by being dichotomous, with cylindrical joint, the extreme ones bearded at the tips.

BARBATA, a species of *NAIS*, about one third of an inch in length, that is found in wet places, in woods, and sometimes adhering to the *Salix planarlis* and other fresh-water snails. The lateral bristles are disposed in tufts, and it has no proboscis. (Müller, Bonnet, &c.) The body is hairy beneath, and each segment furnished on both sides with four divergent bristles; eyes two, and of a black colour; length four lines.

BARBATA, in *Ornithology*, a species of *FRINGILLA* that lives in the mountainous parts of Chili. This bird is about the size of a Canary-bird; of a pale yellow colour, with green wings, spotted with black and red; and has the chin bearded. It is said to sing delightfully, and to be capable of imitating the notes of other birds with the greatest facility. The bill is white at the base, and black at the tip; head black; chin in the young bird yellow, in a few months this changes black, and appears, when full grown, bearded; this is only in the male bird, for the female has no beard, and is of a cinereous colour, with a few spots of yellow on the wing. Molin. Hist. Nat. Chili. Gmel. &c.

BARBATA, a species of *MUSCICAPA*, of an olive-brown colour above; beneath greenish yellow; crown yellow; rump yellow. A native of Cayenne; called by Buffon *barbichion de Cayenne*; and by Latham the whiskered fly-catcher.

The length of this bird is five inches; bill broad, depressed, and shorter than the whiskers. Female greenish-black, yellowish beneath; breast brownish; on the crown an oblong yellow spot.

BARBATED LEAF, in *Botany*, is a leaf terminated by a bunch of strong hairs.

BARBATELLI, BERNARDINO, called *POCHETTI*, in *Biography*, a painter of history, fruit, animals, and flowers, was the disciple of Ridolfo Ghirlandajo at Florence; and from his school he went to Rome, where he applied with such assiduity, and his mind was so engaged by the objects of his contemplation, that he neglected the necessary refreshments of sleep and food. In painting the subjects, to which his attention was principally directed, he not only imitated but equaled nature. His touch was free, light and delicate, and the colouring of his objects inexpressibly true; and besides

his merit in his appropriate style of painting, his historical subjects, from sacred and profane authors, were much admired. He was born at Florence in 1542, and died in 1612. Pittington.

BARBATIA, in *Ancient Geography*, a town of Asia, towards the Tigris. It belonged to the Arabs, according to Pliny.

BARBATINA, or SEMEN *contra*, in the *Materia Medica*, a seed which is efficacious in extirpating worms from the human body, to which children are chiefly liable; it comes from Persia, and the borders of Muscovy. This seed, when good, is plump, of an agreeable scent, and very green. Special care must be taken that it be not dyed green, and that the seed of southern-wood be not fold instead of it.

BARBATISSUS, in *Ancient Geography*, a town of Asia, near the western bank of the Euphrates, on the small river Daradax, south-west of Nicephorium, about 35° 40' lat.

BARBATO, in *Geography*, a river of Spain, which runs into the Atlantic, between Cadiz and the Straits of Gibraltar, about 9 leagues south of Cadiz.

BARBATO, or *Puerto Barbato*, a sea-port town of Spain, in Andalusia, on the coast of the Atlantic, near the mouth of the river Barbato.

BARBATULA, in *Ichthyology*, a species of COBITIS with six cirri; head unarmed and compressed. (Linn.) This is the bearded loche of English writers; enchelyopus, &c. Klein; cobitis fluviatilis, Ray; fundulus, Marsd.

“The bearded loche is a native of Europe and Asia; and is most frequent in fresh-water streams and lakes in mountainous countries. From its habit of lurking at the bottom of the water, on the gravel, it has been called the groundling; but the latter name is now given to the spiny loche, a fish distinguished from the present by having a forked spine under each eye, and is that species of cobitis which Gmelin calls tenia.

“This is a fertile creature; it spawns in the month of March and April, and grows to the length of three or four inches, but seldom larger. It feeds on aquatic insects; and, we are told by Mr. Pennant, is frequent in the stream near Amesbury in Wiltshire, where the sportsmen, through frolic, swallow it down alive in a glass of wine.

“The loche is found in greater abundance in France, and other parts of Europe, than in England; and are in such high estimation for their exquisite delicacy and flavour, that they are often transported with considerable trouble from the rivers they naturally inhabit, to waters more contiguous to the estates of the great. This is usually performed in winter; and it is necessary to keep the water in continual agitation the whole way, as the fish would otherwise die. Frederic I. king of Sweden, had them brought in this manner from Germany into his country, where they have been since naturalized; a circumstance that leads us to conclude they were either scarce, or not originally natives of that country.

“In the dorsal fin of the specimen described, are nine rays, in the pectoral eleven; ventral eight; anal seven; and in the tail nineteen.” *Donov. Brit. Fishes*, vol. i. p. 22.

BARBATUS, in *Entomology*, a species of CERAMBYX (*Prionus*), of a large size, that inhabits South America. The thorax is entire; jaws ferruginous, and very hairy; antennæ of a moderate size. (Fabricius.) Antennæ rough, extreme joint smooth and compressed; shell pitchy; abdomen villous white; legs black.

BARBATUS, a species of SCARABÆUS, that is unarmed,

smooth, and black; vent bearded. (Fabricius.) A native of India.

BARBATUS, in *Ichthyology*, a species of GOBIUS, with fan-shaped pectoral fins; twelve rays in the first dorsal fin, and thirteen in the second. Its native country is unknown. Gmelin.

BARBATUS, a species of LOPHIUS, of a depressed form, with the lower jaw bearded. (Montin. *act. succ.* 1779.) Inhabits the seas in the northern parts of Europe, is about three inches and a half in length, and is extremely rapacious. Perhaps not distinct from *lophius Vespertilio*. Gmelin.

BARBATUS, in *Ornithology*, a species of FALCO, of a whitish red colour, with the back brown; and a black stripe above and beneath the eyes. Gmelin, &c. *Falco barbatus* Linn. *Falturnine eagle* Albin.

Of this bird there is a variety of a rufous colour, with the back black; head and neck above rufous white; quill and tail feathers brown. *Falco aureus* Buff. *Falco barbatus* Ray. *Golden vulture*: Willughby and Latham. A third variety occurs, *falco magus* Gmel. It, in which the cere is bluish; legs and body beneath chestnut, intermixed with white; tail cinereous.

The first kind inhabits the Alps; the two latter the mountainous parts of Persia. It is larger than the golden eagle, measuring rather more than four feet in length; is very daring, flies in flocks, and will attack men as well as animals.

BARBE, or BARB, in *Zoology* and *Commerce*, a kind of horse brought from Barbary, much esteemed for its beauty, vigour, and swiftness. Barbs have a long fine neck, not overcharged with hair, and well divided from the withers; the head is small and beautiful; the ears are handsome and properly placed; the shoulders are light and flat; the withers are thin and well raised; the back is straight and short; the flank and sides are round, and the belly not too large; the haunch bones are properly concealed; the crupper is somewhat long, and the tail placed rather high; the thigh is well formed, and rarely flat; the limbs are fine, handsome, and not hairy; the tendon is prominent, and the foot well made; but the pastern is often long. They are of all colours, but generally grayish. In their movements they are apt to be careless, and require to be checked. They are swift, nervous, light, and make very fine hunters. These horses appear to be the most proper for improving the breed. The stature, however, is not so large as could be wished. They are seldom above four feet eight inches, and never exceed four feet nine inches, or 14½ hands. It is confirmed by repeated experience, that in France, England, &c. they produce foals which grow larger than their parents. Of the Barbary horses, those of the kingdom of Morocco are said to be the best, and next to these are the Barbs from the mountains. The horses of Mauritania are of an inferior quality, as well as those of Turkey, Persia, and Armenia. *Buffon's Nat. Hist.* vol. iii. p. 357. It is a maxim, that barbs grow ripe, but never grow old, because they retain their vigour to the last, which makes them prized for stallions: their mettle, according to the duke of Newcastle, never ceases but with their lives. It is said, they were anciently wild, and ran at large in the deserts of Arabia; and that it was in the time of the cheq Ishmael, that they first began to tame them. It is also affirmed, that there are barbs in Africa that will outrun ostriches; such have been ordinarily sold, according to Dapper, for 1000 ducats, or 100 camels. They are fed very sparingly, and, as Dapper says, with camel's milk. It is added, that in Barbary they preserve the genealogy of their Barbs with as much care as the Europeans do that of their noble families; and that in the

the sale of them, they always produce their titles of nobility. The race of horses is much degenerated in Numidia; the Arabs having been discouraged from maintaining it by the Turkish officers, who are sure to become masters of them. The Tingitanians and Egyptians have had the reputation of preserving the best breed both for size and beauty. Some of these are sixteen hands high, and all of them shap'd, according to their phrase, like the antelope. The good qualities of a Barbary horse, besides the supposed one of never lying down, and of standing still when the rider drops his bridle, are to have a long walk, and to stop short, if required, in a full career. The Barb is very lazy and negligent in all his motions; he will stumble in walking upon the smoothest ground; his trot is like that of a cow, and his gallop very low and very easy to himself. This sort of horse, however, is for the most part finewy, nervous, and excellently wind'd; it is therefore good for a course, if not overweighted. The mountain barbs, which are the largest and strongest, are much esteem'd; they belong to the Alarbes, who value themselves much upon them, and are as fond of them as other nations are, so that they are not easily procur'd. The common barbs have been usually bought in Provence and Languedoc in France, at a moderate price; and many of our persons of fashion in England have them from thence. Barbs, amongst us, fall short of the swiftness attributed to them in their native country: this may be accounted for, partly from the smallness and lightness of their riders, and partly from their not being loaded with heavy saddles and bridles, as in Europe, nor even with shoes. An Arab saddle is only a cloth girt round with a pair of light stirrups, and a sort of pummel to sustain them.

Barbard-Barbs, those descending from the English mares, covered by barb stallions, are, by experience, constantly found both better shap'd and fitter for the saddle, and stronger for service than their sires. Phil. Trans. N^o 105.

BARBE, ST. in *Geography*, a town of Mexico, in New Biscay, in the vicinity of which are very rich silver mines; distant 500 miles N. W. from the city of Mexico. N. lat. 26° 10'. W. long. 110° 5'.

BARBE, the *Ilands of*, lie off the mouth of Green bay, and to the east of cape Den, or the south point of White bay in the Marchigonis river; on the east coast of Newfoundland, and to the north of cape Bonavista.

BARBE, or *Barbet*, in the *Military Art*.—To fire en Barbe, is to fire the cannon over the parapet, instead of through the embrasures; in which case the parapet must not be more than three feet and a half high.

BARBE, or **BARDE**, is also an old term for the armour of the horses of the ancient knights and soldiers, who were accoutred at all points.

Della Crusca says, the barde is an armour of iron or leather, wherewith the neck, breast, and shoulders of the horse are covered.

BARBEAU, in *Geography*, a river of Canada, which runs into the Utwas. N. lat. 45° 15'. W. long. 76° 20'.

BARBED, in *Heraldry*. The five petals or leaves which appear on the outside of a full blown rose are called *barbs*, and are emblazoned thus: a rose gules *barbed* and *seeded* proper, the rose is *red*, the *barbs* green, and the seeds yellow or grey.

BARBED Arrows, signifies an arrow whose head is pointed of an angular form, and jagged. See *PLATE of Heraldry*.

BARBED Horse is a horse barbed at all points, that is, a war-horse completely armed, furnished, and accoutred.

BARBED and Crested, a term used in blazoning to express

the comb and gills of a cock. The usual term in the English blazon is *combed and wattled*.

BARBELE, or **BARBED CROSS**, is by some called *cross cranponce* and *tonnée*. See *PLATE of Heraldry*.

BARBEL, in *Ichthyology*. See *CYPRINUS BARBUS*.

BARBELA, or **VERBELLA**, in *Geography*, a river of Africa, in Congo, which joins the Zaire near its mouth.

BARBELICOTÉ, in *Ecclesiastical History*, an ancient sect of Gnostics, spoke of by Theodoret. The doctrine of the Barbelicote was, that one of the sons, possessed of immortality, had commerce with a virgin spirit named *Barbeloth*, who demanded of him, first preference, then incorruptibility, and lastly eternal life, all which were granted to her: that being one day in a gayer humour than ordinary, she conceived, and afterwards brought forth light, which being perfected by the union of the spirit, was called *Christ*; the child Christ desired to have understanding, *wis*, and obtained it; after which, understanding, reason, incorruptibility, and Christ, united together; and from their union arose autogenes, *αυτογενος*. To these fables they add divers others. They were also denominated *Barbariani*.

BARBELLA, **EMANUEL**, of Naples. It would be unjust not to bestow a few words on this pleasing and peculiar player on the violin of the old school. The father of this singular but worthy and inoffensive character, was an eminent performer on the violin, and leader of the opera band at Naples in the beginning of the last century, during the life of Corelli, when his scholar *Caminiari* arrived in that city from Rome. (See *CORELLI*, and *CAMINIARI*.) On the first hearing of the younger Barbella, he surpris'd no one who had heard Giardini and other famous violinists of the new schools. He was not young, indeed, when the parallel was drawn, and solo playing was disregarded at Naples, where vocal composition and singing were chiefly cultivated in the conservatories, and patronized by the public, so that teaching and orchestra playing were Barbella's chief employment and support; and for the latter he was ill-qualified by the softness of his tone, and the shortness of his bow. He performed, however, most admirably the famous Neapolitan air, which the common people constantly play at Christmas to the virgin. Barbella executed it with a drone kind of bagpipe base, in a very humorous though delicate manner. But as a solo player, though his tone was very even and sweet, it was somewhat languid and inferior in force to that of Nardini of the same school, and indeed to that of several others then in Italy; but he knew music well, had much fancy in his compositions, with a tincture of not disagreeable madness.

He was most remarkable for his sweet and insinuating manner of playing Calabrese, Loccese, and Neapolitan airs, and among the rest a humorous piece composed by himself, which he calls *Tinna Nonna*; it is a nursery tune, or *Lullaby*, excellent in its way, and with his expression, was extremely captivating.

Barbella was the most obliging and best-natured of mortals; his temper has been said to be as soft and sweet as the tone of his violin.

In a correspondence with the author of this article, who had request'd of him an account of the Neapolitan school of music, and above all, of his own studies; as his answer concerning himself was short and characteristic, we shall here insert a translation of it.

“Emanuele Barbella had the violin placed in his hand when he was only six years and a half old, by his father Francesco Barbella. After his father's decease he took lessons of Angelo Zaga, till the arrival of Paquillino Bini, a scholar

a scholar of Tartini, in Naples, under whom he studied for a considerable time, and then worked by himself. His first instructor in counterpoint was Michele Gabbaloni; but this master dying, he studied composition under the instructions of Leo, till the time of his death; and pleasantly adds: *Non per questo, Barbella, è un vero afiao che non fa niente*: "Yet, notwithstanding these advantages, Barbella is a mere ass, who knows nothing."

This modest and ingenious musician, and true follower of Tartini's principles, died at Naples 1773. His worthy disciple, signor Raimondi, with more force in public, has the same sweetness of tone and temper in private.

BARBER, a person who makes a trade of shaving, and dressing the wigs and hair of other men, for money. There were no barbers at Rome before the year A. U. C. 454. Varro reports that Titinius Mena brought them thither from Sicily. The barbers' shops very soon became the resort of idlers and gossips. To this purpose, Horace, in expressing what was public and notorious, says, that all the barbers know it:

"Omnibus et lippis notum et tonforibus esse."

Besides curling the hair, and shaving the beard, the ancient barbers also trimmed the nails. Thus Plautus (Aulul. ii. 4. 33.): "Quum ipsi pridem tonsor unguis demiserat;" and Tibullus (l. 2. 11.):

Artificis dosiâ subsecuisse manu?"

Anciently a lute or viol, or some such musical instrument, was part of the furniture of a barber's shop, which was then frequented by persons above the ordinary rank, who resorted thither for the cure of wounds, or to undergo some surgical operations, or as it was called to be *trimmed*, a word which signified either shaving or cutting and curling the hair. These, and also letting of blood, were the ancient occupations of the barber surgeon. The musical instruments in his shop were for the amusement of waiting customers, and answered the end of a newspaper, with which it has been usual for such to entertain themselves. The origin of the "barber's pole" has been the subject of various conjectures among etymologists. Some have supposed it to have been derived from the word *poll*, or head; but the true intention of this party-coloured staff was to shew that the master of the shop practised surgery, and could breathe a vein, as well as take off the beard; such a staff being to this day, by every village practitioner, put into the hand of a person undergoing the operation of phlebotomy. The white band, which encompasses the staff, was designed to represent the fillet, thus elegantly turned about it.

The barbers were incorporated with the surgeons of London, but not to practise surgery, except drawing of teeth, &c. 32 Hen. VIII. c. 42; but separated by 18 Geo. II. c. 15.

BARBERS, *Company of*. See COMPANY.

BARBER SAND, in *Geography*, lies within the sands which form Yarmouth roads, and parallel with the northern part of them, and of the coast, beginning off the town of Caistor. There is within it a good channel along the shore, in five, six, or seven fathoms, till you go out north at Winterton Ness.

BARBERAIN, or BARBERIAN, an island off the coast of the island of Ceylon, in the East Indies, about 15 leagues south of Columbo on the western side; in N. lat. 6° 25'. and E. long. 80°.

BARBERANO, a town of Italy, in the state of the church, and province of Patrimonio; six miles from Bieda.

BARBERINI, MAFFEO, in *Biography*. See URBAN VIII.

BARBERINO, FRANCIS DA, an Italian poet, was born in 1263 at Barberino, a castle of Valdeffa, and educated for the profession of the civil and canon law at Padua and Bologna. Upon his removal to Florence in 1294, he served two bishops in the way of his profession, and made frequent journeys to the papal court at Avignon. He was honoured with the degree of doctor of laws by Clement V.; and attended the general council at Vienna in 1311. Amidst his professional pursuits, he cultivated poetry, and published a work, intitled, "Documenti d'Amore," which treats of moral philosophy, and consists of twelve parts, each of which has for its subject some virtue and its rewards. His style is not distinguished by ease or elegance, but favours too much of Provençal poetry; and yet the author has been reckoned among the good writers and founders of the language. This poem was first printed at Rome in 1640, adorned with fine figures. Another work, in verse, on the Manners of Women, is preserved in MS. in the Vatican. Barberino died of the plague at Florence in the year 1348. Gen. Dict. Nouv. Dict. Histor.

BARBERINO, in *Geography*, a town of Italy, in the duchy of Tuscany, seated on a mountain, 16 miles south of Florence.

BARBERINO is also a town of Italy, in the duchy of Tuscany, situated at the foot of the Apennines, on the side of the river Sieve, four miles west of Scarperia. N. lat. 43° 40'. E. long. 12° 15'.

BARBERNOLA, or BLANC, *Cape*, lies on the coast of Asia, in N. lat. 38° 9', and E. long. 26° 27'.

BARBERRY, in *Botany* and the *Materia Medica*. See BERBERIS.

BARBESIEUX, in *Geography*, a town of France, and principal place of a district in the department of the Charente. It has a manufacture of linen cloth, and near it is a medicinal spring. N. lat. 45° 28'. W. long. 0° 15'.

BARBESOLA, or BARLESULA, in *Ancient Geography*, a river of Spain, in the country of the Bastuli. Ptolemy and Pliny.

BARBESOLA, *Barbesula*, or *Barbesul*, a town of Spain, in the country of the Bastuli, situated on the strait between Cartia and Tranfducta. Ptolemy, Pliny, and Mela.

BARBET, in *Zoology*. Buffon calls the *water-dog* of Pennant, *canis aquaticus* of Gmelin, &c. *le grand barbet*; and *canis minor* Gmel. *le petit barbet*. Hist. Nat.

BARBET, in *Ornithology*, the English name of a genus of birds in Latham's Synopsis, corresponding with that of *bucco*, Linn. See BUCCO.

BARBETICUM JUGUM, in *Ancient Geography*, a promontory of Spain, in Bætica.

BARBETS, in *Geography*, the name of the inhabitants of several valleys in Piedmont, particularly those of Lucern, Angrona, Perusa, and St. Martin.

BARBEYRAC, CHARLES, in *Biography*, an eminent physician of France during the seventeenth century, was the son of a gentleman of Ceresse in Provence. He studied physic at Aix and Montpellier, and in 1649 took his doctor's degree in the university of the latter place, where he settled; and in 1658, became a candidate for the medical professorship, but on account of his being a protestant, he was ineligible. In the disputations on this occasion he acquired great reputation, and his advice was sought in difficult cases by persons both in his native country and also in foreign kingdoms. He declined the office of being physician to Mademoiselle d'Orleans, preferring liberty to the shackles of a court; and at Montpellier, where he resided, he was attended in his visits by many students to whom he gave clinical instructions. His practice was distinguished by its simplicity,

simplicity and energy; and he introduced many valuable reforms into the state of medicine in that country. He was no less eminent for his condescension and liberality than for his medical reputation, and he alike visited the poor and the rich. The celebrated Mr. Locke was particularly acquainted with him at Montpellier, and testified to his honour, that he never knew two men more familiar in their manners and opinions than Barboyrac and his friend Sydenham. After an uninterrupted course of practice for 50 years, he died of a fever in 1699, in his 70th year, leaving a son of his own profession, and two daughters. The only works he published were "Traitéz nouveaux de Médecine, contenant les Malades de la Poitrine des Femmes, et quelques autres Maladies selon les nouvelles Opinions," 12mo. 1651; and "Quelques Médicaments de Médecine," 4to. 1658. A work, intitled, "Médicamentum Coactivum, &c." published in 1751, is ascribed to him upon uncertain authority, according to the editor M. Fajon. Haller. Bibl. Méd. Pract. Gen. Biog.

BARBEYRAC, JOHN, the nephew of the preceding, was born in 1674 at Barzès, whence he withdrew to Lausanne in 1695. His father designed him for the profession of theology, but his own inclination led him to the study of jurisprudence; and he became eminent in that particular branch of it which comprehends the law of nature and nations. After teaching the Bell's Lettres in the French college at Berlin, he was appointed in 1710 to the new professorship of law and history founded at Lausanne by the magistrates of Berne, which he occupied seven years. In 1717 he was removed to the chair of law at Groningen, and this station he long occupied with general applause. His works are numerous and valuable. His French translation of Puffendorf's "Law of Nature and Nations," and his treatise "On the Duties of a Man and a Citizen," and on "Grotius on the Rights of War and Peace," were enriched with learned prefaces and notes, which enhanced the value of the originals. He also translated two discourses of Noodt, "On the Power of the Sovereign," and "On Liberty of Conscience;" a treatise of Bynkerhook "On the civil and criminal Powers of Ambassadors; some of "Tillotson's Sermons;" and Cumberland's Latin treatise "On Natural Laws." Barbeyrac was also the author of several original works. But that which excited the greatest attention was his "Treatise on the Morality of the Fathers," 4to. 1728, in reply to the *Benedicte* Caillier's "Apology for the Fathers," occasioned by Barbeyrac's free strictures on them in his preface to the translation of Puffendorf. His "Treatise on Gaming," in two volumes, 8vo. was printed in 1700; his "Defence of the Rights of the Dutch East India Company against the Pretensions of the People of the Austrian Netherlands," in 1725; and "The History of ancient Treaties dispersed in Greek and Latin authors to the time of Charlemagne," fol. in 1739. He also inserted literary and critical remarks in different journals, and published some academical discourses. He closed a life of learned labour and moral worth about the year 1747. *Nouv. Dict. Histor.*

BARBI, in *Natural History*, a species of *LECHORHYNCHUS*, of an ovate shape, yellow colour, flattened; neck long, white, cylindrical; and cyathiform (glass or pot-shaped) at the end, found in the intestina of the barbel.

BARBICAN. See BARBACAN.

BARBICAN, in *Ornithology*, the name of the Gmelinian *byco dubius*, or doubtful barbet, in Buffon's *Hist. Birds*. *Barbu* is also a name given by that writer to all the birds of the *byco* genus, which he describes.

BARBICANAGE, BARBICANAGIUM, in our *Old Writ-*

ers, money given for the maintenance of a barbiere, or watch-tower; or a tribute towards repairing or building a bulwark.

BARBICON (BARBICON DE CAYENNE), in *Ornithology*, the name of the *Mysticifa barbata* or Gmelin, in Buffon's *Hist. Birds*.

BARBICORNIS, in *Zoology*, a species of *BRENTUS* that inhabits New Zealand. It is cylindrical, with the back very low and bearded beneath; wings cast elongated and flattened. Gmelin. This is *CERCURIO Barbicornis* of Fabricius's *Spec. Inf.* 171.

BARBICORNIS, a species of *CERYNETHUS*, with the thorax spinous; four first joints of the antennæ bearded with black; body testaceous, variegated with black. Linn. A native of Asia.

BARBICORNIS, a species of *CIMEX* (*Relapsus*) that inhabits Sierra Leone. This is of a black colour, with the thorax and base of the abdomen olive. Fabricius. *Off.* The thorax is sometimes, though rarely, black, and the antennæ in one sex is bearded.

BARBICORNIS, a species of *TIPULA*, of a black colour; antennæ plumose, and simple at the tip. It inhabits Europe. This is a small species. Gmelin.

BARBIER D'AUCOUR, *Jean*, in *Biography*, a counsellor, and man of letters, was born of mean parentage, in 1641, at Langres, and educated at Dijon. On his removal to Paris, he was entered at the bar, and became a counsellor of the parliament of Paris. He distinguished himself by the excellence of his "factums" or written pleadings; but being obliged, either through want of presence of mind or failure of memory, to stop at his first public pleading, he renounced the practice of his profession. In 1677 the minister Colbert appointed him preceptor to his eldest son, and in 1683, he was elected into the French Academy. Colbert conferred on him some lucrative employments; but, on his death, he was under a necessity of returning to the bar, and gained great reputation by the defence of Le Brun, the domestic of a lady of Paris, who had been falsely accused of murdering his mistress. He was soon after carried off by an inflammation of the lungs in 1694. His circumstances were so reduced, that when he was visited, in his last illness, by a deputation from the academy, which expressed concern at finding him so ill lodged, he replied, "It is my consolation, and a very great one it is, that I have no heir to my wretchedness." When the abbe Choisi, who was one of them, said, "You leave a name that will never die;" "Alas! (replied D'Aucour) I do not flatter myself in that respect; if my works have any intrinsic value, I have been wrong in the choice of my subjects; I have employed myself in criticism, which has no long duration; for if the work that is criticized, should fall into contempt, the criticism falls with it, since it is immediately perceived to be useless; but if, in spite of the criticism, the book maintains its ground, the criticism is equally forgotten, because it is thought to be unjust." Barbier was in early life embroiled with the Jesuits, who by way of contempt called him "Sacrus," in consequence of his having inadvertently used that word instead of "Sacer," in his reply to one of them. Referring this offence, he made the society and its writers the objects of his attacks; and he gained great credit as an ingenious writer by a work, intitled, "Sentimens de Cleanthe sur les Extractions d'Arille et d'Engene, par le Pere Bouhours, Jésuite," 12mo. 2 vols. 1671, 1672. This work has been often cited as a model of refined criticism, equally just and witty; and Bouhours could not support himself against it. Some other pieces of this author against the Jesuits, abounding with coarse railery, did him no honour. In 17

two satires, written in verse against Racine, he was unsuccessful. Besides his "factums" for Le Brun, he published some others. *Nouv. Dict. Hist.*

BARBIER, MARY ANNE, was a native of Orleans, and ranked among the dramatic writers of France. Her tragedies, and a comedy in verse, were represented at Paris, and printed in one volume, 12mo. The subjects are well chosen, but the characters, and those of the men especially, are without force, and the style is diffuse and profane. Mad. Barbier was intimate with the abbé Pellegrini, who is said to have bestowed, at least, correction on her works. She died in an advanced age at Paris, about the year 1745. *Nouv. Dict. Hist.*

BARBIER, *Mijlress*, first appeared as a new English singer, on the revival of the opera of *Almahide* in 1711, while questions were asked in Italian, and answered in English, and *e contra*. Her timidity on first appearing on the stage, gave birth to an admirable Spectator (No. 131), in which Mr. Addison apologises for, and commends, diffidence and modesty with a sympathetic zeal and sensibility. It is well known, that this excellent writer, with all his learning and abilities, was never able to perform his part in public as a speaker, when he was secretary of state and in parliament, long after this paper was written; and here, by a kind of precognition, he extenuates his fault before it was committed. With respect to Mrs. Barbier's distress on her first facing an audience on the stage, Mr. Addison has put it in the most amiable light possible: "this sudden desertion of oneself," says he, "shews a diffidence, which is not displeasing; it implies at the same time the greatest respect to an audience that can be: it is a sort of mute eloquence, which pleads for their favour much better than words can do; and we find their generosity naturally moved to support those who are in so much perplexity to entertain them. I was extremely pleased," continues he, "with a late instance of this kind at the opera of *Almahide*, in the encouragement given to a young singer, whose more than ordinary concern on her first appearance, recommended her no less than her agreeable voice and just performance." This lady was a native of England, who continued to sing at the opera several years, and afterwards was a favourite concert and play-house singer, till the year 1729.

In the year 1717, it seems as if she had a little vanquished her bashfulness in private, however it may have incommoded her in public; for she had mustered courage sufficient to elope from her father's house with a person that was *suspected* to be of a different sex. During her absence, Mr. Hughes wrote the following pleasant verses:

"O yes!—hear all ye beaux and wits,
Musicians, poets, 'squires, and cits!
All, who in town or country dwell,
Say, can you tale or tidings tell
Of Tortorella's hasty flight?
Why in new groves she takes delight;
And if in concert, or alone,
The cooing murmurer makes her moan?"

Now learn the marks by which you may
Trace out and stop the lovely stray.

Some wit, more folly, and no care,
Thoughtless her conduct, free her air;
Gay, scornful, sober, indiscreet,
In whom all contradictions meet,
Civil, affronting, peevish, easy,
Form'd both to charm you and displease you;
Much want of judgment, none of pride,
Modish her dress, her hoop full wide;
Brown skin, her eyes of sable hue,
Angry when pleas'd, when vex'd a shrew.

Genteel her motion when she walks,
Sweetly she sings, and loudly talks;
Knows all the world, and its affairs,
Who goes to court, to plays, to prayers,
Who keeps, who marries, fails, or thrives,
Lead honest or dishonest lives;
What money match'd each youth or maid,
And who was at each masquerade;
Of all fine things in this fine town,
She's only to herself unknown.

By this description, if you meet her,
With lowly bows and homage greet her,
And if you bring the vagrant beauty
Back to her mother and her duty,
Ask for reward a lover's bliss,
And, if she'll let you, take a kiss;
Or more, if more you wish and may
Try if at church the words she'll say,
Then make her, if you can—obey.

BARBIERI, GIOVANNI FRANCESCO, called *Guercino Da Cento*, an eminent historical painter, was born at Cento, a village near Bologna, in 1590; and was at first the disciple of Benedetto Gennari, but afterwards studied for some time in the school of the Caracci. He preferred the style of Caravaggio to that of Guido or Albano, and conceived it impossible to imitate nature truly, without the assistance of strong lights and shadows; and on this principle, his light was admitted into his painting room from above. By this opposition of his strong lights and shadows he unquestionably gave such force to his pictures, that few, those of Caravaggio excepted, equal them in their effect. His principal attention was employed in acquiring perfection of colouring, from a persuasion that few persons are qualified to discern the elevation of thought which constitutes the excellence of a composition, or are perhaps capable of examining even the correctness of any part of a painting; whereas every eye, and even every imperfect judge of a picture, may be sensibly affected by the form and beauty of the colouring. His taste of design was natural, easy, and often grand, but without any extraordinary share of elevation, correctness, or elegance. The airs of his heads are often destitute of dignity, and his local colours of truth: nevertheless his colours possess great union and harmony, although his carnations are not very fresh; and in all his works there is a powerful and expressive imitation of life, which will for ever render them estimable. Towards the decline of life, observing that the clearer and brighter style of Guido and Albano had attracted the admiration of all Europe, he altered his manner even against his judgement. But he apologized for this conduct by declaring that he had formerly painted for fame, and with a view of pleasing the judicious; but he now painted to please the ignorant, and to enrich himself. The most capital performance of Guercino is the history of St. Petronilla, which is considered as one of the ornaments of St. Peter at Rome. He died in 1666. Pilkington.

BARBIERI, *Paulo Antonio, Da Cento*, the father of the preceding artist, was born at Cento in 1596, and selected for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of colours, with great tenderness of pencil, and a strong character of truth and life. Pilkington.

BARBILLON, in *Ichthyology*, a name given by Broussonet, (Act. Paris.) to the *SQUALUS CIRRATUS* of Gmelin.

BARBING is sometimes used in *Ancient Statutes* for shearing. Cloth is not to be exported till it be barbed, rowed, and shorn. 3 Hen. VII. c. 11.

BARBIROSTRIS, in *Entomology*, a species of *CURCULLIO*, found in China and some other parts of Asia. It is black; snout bearded; anterior legs tridentated. Fabricius. *Donov. Inf. China, &c.*

BARBITANI MONTES, in *Ancient Geography*, mountains of India, on this side the Ganges, in which, according to Ammianus Marcellinus, are the springs of many rivers that flow into the Indus.

BARBITON, an ancient musical instrument, of which nothing is known but the name; and Rousseau has not even ventured to give us that. Complaints are frequently made of the darkness in which critics, commentators, and historians leave the subject of ancient music; which none have more cause to lament than those who have spent the most time and labour in its investigation. But as no record or memorial has been found, which ascertains the invention, form, or species of instrument called the *barbiton*, would mere conjecture satisfy the complainants? Messrs. Framery and Castillon, more courageous than the citizen of Geneva, have told us, in the new *Encyclopedie*, all that is pretended to be known about it; though the former begins by telling us that it is an instrument about which nothing is known. The ancients and moderns have frequently confounded it with the lyre. Dacier conjectured that it was a stringed instrument; and deriving its name from *barumiton*, which implies *thick strings of flaxen thread*, he concludes that it was an instrument with thick strings. It is certain that flax was in use for strings to musical instruments, before the art was known of making them of the bowels of animals. Horace calls this instrument Lesbian, *Lesboum barbiton*, ode i. lib. 1; and 32 of the same book, *Lesbio primum modulate civi*, "Thou, O barbiton, first touched by a citizen of Lesbos," meaning Alcæus, to whom he ascribes the invention. But, says M. Castillon, we may conclude from what Musonius asserts of this instrument, in his treatise "De Luxu Græcorum," that they made a kind of concert with the *pellis* of the Lydians. (See *PECTIS*.) He assures us that Terpander was the inventor of it. Julius Pollux also calls it barbiton barumiton. Athenæus relates that they likewise called it *barimus*, and attributes the invention to Anacreon. We hope the grumblers will be perfectly enlightened by this *clear, consistent, and satisfactory* account.

BARBLE, or **BARBEL**, in *Ichthyology*. See **BARBUS**.

BARBLES, in the *Manege*, knots of superfluous flesh growing in the channels of a horse's mouth; that is, in the intervals which separate the bars; and obstruct his eating.

These are also called *barbes*; and obtain in black cattle as well as horses.

For the cure, they cast the beast, take out his tongue, and clip off the barbles with a pair of scissars, or cut them with a sharp knife; others choose to burn them off with a hot iron.

BARBONI, in *Ichthyology*, a name formerly given by many to the *MULLUS BARBATUS*; which see.

BARBONNE, in *Geography*, a town of France, in the department of the Marne, and chief place of a canton in the district of Sezanne, 1½ league south from Sezanne.

BARBORA, an island of Africa, opposite to the kingdom of Adel, so called after a town of the same name upon the neighbouring continent. This island, which is almost contiguous to the Terra Firma, is very fertile, and produces plenty of corn, fruits, and cattle. The inhabitants are negroes clothed in the fashion of the natives of Adel, industrious in trade, and great breeders of cattle, for which the soil affords excellent pasturage. The produce of this island is exported into other countries. The city of Barbora lies

at the bottom of a convenient bay; and was for a long time a kind of rival in commerce with Zeila, and no less the place of resort for foreign merchants. It is situated over against the city of Aden, and made once a considerable figure, but was plundered and burnt by the Portuguese fleet in the year 1518; but the inhabitants, being previously apprized of their design, conveyed themselves and their most valuable effects away.

BARBOSA, ARIAS, or AYLES, in *Biography*, a native of Aveiro in Portugal, and one of the restorers of classical literature in his own country and in Spain. Having commenced his education at Salamanca under many disadvantages, he pursued his studies, particularly that of Greek, which he cultivated with great ardour, at Florence, under Angelo Politiano. After his return to Salamanca in 1494, he taught there for 20 years, in connection with Antony de Lebrixa, who, with Andrew de Refenda, was also one of the principal promoters of useful learning in Spain. Barbosa directed special attention to poetry, and published a small volume of Latin poems, which were commended for the harmonious structure of the verse. He was afterwards employed for seven years as preceptor to the two princes of Portugal, Alphonso and Henry; and then retired to domestic life, in which he died at an advanced age in 1540. Besides the poems above mentioned, Barbosa published several works, which contributed at the time to the progress of literature, but are now forgotten; such as, "Commentaries on the poem of Arator," "Quodlibeticæ Quæstiones," "De Profodia," &c. Moreri. *Nouv. Dict. Hist.*

BARBOSA, Peter, a celebrated lawyer, was born at Viana, in Portugal, and became first professor in the university of Coimbra. Although he occupied several important stations, and was appointed by Philip II. of Spain, when he became master of Portugal, one of the four counsellors of the council of state, and afterwards chancellor of the kingdom, he prosecuted his professional studies; and, in 1595, he published an ample commentary on the article in the "Digests," on the recovery of dowry after the dissolution of marriage. In 1613, the works left by him in MS., which were commentaries on the "Digests," art. "On Judgments," were published by his nephew, and so well received, as to be reprinted at Frankfurt in 1715. Other posthumous treatises were published at Lyons in 1662. Moreri. *Nouv. Dict. Hist.*

BARBOSA, Emanuel, an eminent Portuguese lawyer, was born at Guimaraes, and was king's counsellor for the province of Alentejo. In 1618, he published a treatise relative to contracts, last wills, and crimes, according to the Spanish and Portuguese law. In 1638, he published a work, "De Potestate Episcopi;" and in that year he died, aged near ninety years. Moreri. *Nouv. Dict. Hist.*

BARBOSA, Augustin, son of the preceding, studied civil and canon law under his father, and afterwards at Rome, with incessant assiduity, searching libraries in the day, and composing in the night. It is related of him, that he received a scrap of manuscript wrapping some salt fish, which he purchased, and that he rescued the remainder from a similar use; and thus formed the work "De Officio Episcopi," which he corrected and published in his own name. A prejudice was thus conceived against him, and several of his treatises on the canon law were ascribed to his father. He was, however, a very studious man; and on his return to Spain in 1632, he pursued the same kind of life which he had passed at Rome. His skill in ecclesiastical causes occasioned his promotion, in 1648, to the bishopric of Ugen-

to, in the territory of Otranto. Having been consecrated at Rome in the following year, he returned to Ugento with a view of performing the duties of his office, but died there within a few months. His works were numerous, and were printed at Lyons in 1716 and the following year, in 16 tomes folio. *Moreri. Nouv. Dict. Hist.*

BARBOSTHENES, in *Ancient Geography*, a mountain of Greece in the Peloponnesus, 10 miles from Laedemon. *Livy.*

BARBOT, Penn.; BARBOTA, Rond. l.; in *Ichthyology*, synonymous names of the species of *GADUS* called *LOTA* by *Linnaeus*.

BARBOTES ROCKS, in *Geography*, are two rocks which are about half a league N.N.W. from the Calmaridiers, and appear every tide.

BARBOTINE, a seed otherwise call'd *L. f. non fantonicum*, and *simen contra verms*, in English *wormseed*.

BARBOULT POINT, lies within the south-west point of the bay of Cancale, to the east of St. Maloes, on the coast of France.

BARBOUR, or BARBER, JOHN, in *Biography*, an eminent divine, historian, and poet, was born in the city of Aberdeen, as some say, about the year 1330, but according to others, in 1326. Having received a learned education, he entered into holy orders, and was promoted by king David II. to the archdeaconry of Aberdeen, A.D. 1356. Such was his love of learning, that he continued to prosecute his studies after his promotion; and with this view he prevailed on his own sovereign, David Bruce, with whom he was in great favour, to obtain permission from Edward III. to study at Oxford. The grant for this purpose was dated at Westminster, Aug. 13th, A.D. 1357. He was also appointed by the bishop of Aberdeen, one of the commissioners for the ransom of David II. king of Scotland; and he obtained permission from Edward III. A.D. 1365, to travel through England to St. Dennis, near Paris, with six horsemen as his attendants. Barbour was not only famous for his extensive knowledge in the philosophy and divinity of those times, but still more admired on account of his admirable genius for English poetry; in which he composed, as he tells us, in 1375, a history of the life and glorious actions of Robert Bruce king of Scotland, at the desire of king David Bruce, his son, who granted him a considerable pension for his encouragement, which he generously bestowed on an hospital at Aberdeen. This work is not only remarkable for a copious circumstantial detail of the exploits of that illustrious prince, and his brave companions in arms, Randolph earl of Moray, and the lord James Douglas, but also for the beauty of its style, which is not inferior to that of his cotemporary Chaucer. This poem passed through about twenty editions in Scotland since the year 1616, in which the first edition, that can be discovered, was printed at Edinburgh, in 12mo. But these editions were all modernized. An edition of this most ancient production of the Scottish muse extant, in the language and orthography of its author, from a MS. written in 1489, and preserved in the advocat's library at Edinburgh, was printed by Mr. Pitkerrow, under the title of "The Bruce," with notes and a glossary, in 1790, in 3 vols. 12mo. The following verses, distinguished by their solemnity, afford a specimen of the author's talent at rural description, and also of the state of the English language in his time.

"This was in midle of month of May,
When birds sing on ilk spray,
I heard their note, with fevly soun,
For soltness of the sweet seaoun.

And leavis of the branchis sprceids,
And blossomis bright, beside them, breeds,
And fieldis thrawel are with flow'rs
Well favouring of feir colours;
And all things worthis, blyth, and gay."

Barbour is said to have died at an advanced age in 1396, but the time and circumstances of his death are not satisfactorily ascertained. *Hemly's History*, vol. viii. p. 249. *Parkerton*, ubi supra. *Wharton's Hist. Eng. Poetry*, vol. i. p. 313.

BARBUDA, or BERBUDA, in *Geography*, one of the British Caribbee islands in the West Indies, is a small island, about 20 miles long and 12 broad, and lies about 15 miles north-east of Montserrat. This island was planted soon after the English had settled upon St. Christopher's, in 1628, and called "Dulcina" from its beautiful appearance. It is the property of the Codrington family, whose ancestor Colonel Codrington obtained a grant of it for his important services to the crown of England in the West Indies, and is bid to yield above 5000l. a year. Upon his death in 1710, he bequeathed two plantations in Barbadoes, and part of Barbuda, valued at 2000l. per annum, to the society for propagating the gospel for the instruction of the negroes in Barbadoes and the other Caribbee islands in the Christian religion, and for erecting and endowing a college in Barbadoes. This is the only proprietary government of all the English Caribbee isles; and the appointment of a governor is in the Codrington family. The land lies low, but is fertile; and the inhabitants are chiefly employed in breeding black cattle, sheep, kids, fowls, and all kinds of domestic flock; in planting Indian corn, and in other parts of husbandry; and they supply the neighbouring islands with these articles. The island, however, is capable of yielding, by cultivation, citrons, pomegranates, oranges, raisins, Indian figs, maize, cocoa-nuts, cinnamon, and pine-apples, with various kinds of wood and drugs, such as brasil, ebony, pepper, and indigo. There are some large serpents upon this island, which, not being poisonous, are useful in destroying rats, toads, and frogs; and others so venomous, that their bite proves mortal, unless an antidote be applied in the space of two hours. The coast abounds with rocks: but on the west side of the island there is a well-sheltered road, and there are two shoals, which run more than two leagues into the sea, from the north-west and south-west points. The inhabitants are computed to be about 1500. N. lat. 17° 49' 45". W. long. 61° 55'.

BARBUE, RIVIERE-A-LA, a river of North America, empties itself into lake Michigan, from E.S.E. between Raisin and Marame rivers. Its mouth is 60 yards wide, and lies 72 miles N. by W. from fort St. Joseph. This is also the name of a river, which discharges itself into lake Erie, from the N. by E. 40 miles W.N.W. from the extremity of Long point, in that lake, and 22 E. by S. from Tonty river.

BARBULÆ, in *Botany*, a name given by *Pliny* to the fern *fosculli*.

BARBUS, in *Ichthyology*, a species of *CYPRINUS*, having seven rays in the anal fin; beards four; second ray of the mid dorsal fin serrated on both sides. *Linnaeus. Mus. Ad. Fr. &c.*

This is the *barbel* of the English: a common inhabitant of most fresh waters in Europe, and easily distinguished from the other species of carp, or cyprinus genus, to which it belongs, by the upper jaw being advanced far beyond the lower one, and in having the four beards appendant, from which the appropriate name of barbus or barbel is derived. This fish, during

during the summer, prefers the rapid currents and shallows of rivers, and retires at the approach of winter to the more full and deeper places. They live in societies; lurking in holes along the sides of the water under shelter of the deepest banks, and feed on smaller fish and worms and flesh of all kinds, for which they dig in the banks like swine. In the day-time they love to lurk occasionally among weeds, and between the stones in retired parts of the river, and wander out at night in search of prey. They spawn in April, and begin to be in season in May and June.

The flesh of the barbel was never in great esteem for the table. Mr. Pennant quotes a passage in Antonius, which, as he observes, is no panegyric on its excellence, for he lets us know it loves deep waters, and that when it grows old, it is not absolutely bad:

“Laxos exeret *barbe* natatus

To melior pejore ævo, tibi coarigit mi

Spurium ex numero non invidiæ senectus.”

And he adds himself, that “they are the worst and coarsest of fresh-water fish, and seldom eat but by the poorer sort of people, who sometimes boil them with a bit of bacon to give them a relish.”

“The barbel,” says old Walton, “though he be of a fine shape, and looks big, yet he is not accounted the best fish to eat, neither for his wholesomeness nor his taste, but the male is reputed much better than the female, whose spawn is very hurtful.”

Again, when speaking of Roudelinius, he makes this remark on the spawn, “we agree with him, that the spawn of the barbel, if it be not poison, as he says, yet that it is dangerous meat, especially in the month of May; which is so certain, that Gesner and Gassius declare, it had an ill effect upon them even to the endangering of their lives.”

Sir John Hawkins, in his Annotations, inclines to the same opinion, and gives an instance of his servant being taken dangerously ill after having incautiously eaten of this fish. M. Bloch, and some other ichthyologists, contend that this is a vulgar and most absurd prejudice. M. Bloch in particular observes, that himself and all his family have eaten the spawn of the barbel, and never experienced the slightest ill effects from it. *Donov. Brit. Fishes.*

The time for taking this fish is very early in the morning, or late in the evening: the place should be baited with chopped worms some time before; and no bait is so good for the hook as the spawn of the salmon, or some other fish: in defect of these, lob-worms will do; they must be very clean and nice, and the hook carefully covered, otherwise he will not touch them. Old cheese steeped in honey is also a very fine bait. The best season for angling for this fish is from May to August.

BARBY, in *Geography*, a small bailiwick of Germany, in the circle of Upper Saxony, forms a part of the circle of Wittenberg, and was granted in 1748 and 1765, to the count of Reufs, and the society of united brethren, or Moravians.

BARBY is also the name of a town of Germany, in the circle of Upper Saxony, seated on the Elbe, near the mouth of the Saale, in which is a Moravian academy for the instruction of youth, 14 miles N.W. of Dessau, and 14 S.S.E. of Magdeburg. N. lat. 51° 37'. E. long. 11° 51'.

BARBYLA, in *Botany*, a name by which Theophrastus, and others of the early writers, have called the common damask prune.

BARCA, in *Geography*, an extensive desert country, situate on the south coast of the Mediterranean, between Tripoli and Egypt, and forming part of the great desert, or Sahara.

It extends in length from west to east from about the 35th degree of longitude to the 46th degree, and in breadth from north to south about 30 leagues, though its confines on the south side are very imperfectly ascertainable. It is, in general, a dry and barren land, whence the Arabs have called it “Sohart,” or “Ceyrari Barka,” that is the “Desert,” or “Road of Whirlwinds and Hurricanes.” Water is scarce; and, except in the neighbourhood of its towns and villages, if they may be so called, where the ground produces some grain, such as corn, millet, and barley, quite dead and uncultivated. The article, where the poor inhabitants produce they are obliged to exchange with their no less indigent neighbours for dates, sheep, and camel. This country forms part of the ancient Cyrenaica and Marmarica (see CYRENAICA, and MARMARICA): in the most desert and dangerous district of it stood the temple of Jupiter Ammon (see AMMON.) This spot, though in former respects pleasantly situated, is surrounded by quick and burning sands, which are very pernicious to travellers, and sometimes overwhelm whole caravans. Against this temple Cræsus and an army of 50,000 men, marched from Thebes in Upper Egypt; but their fate is uncertain, as they never returned either to Egypt or to their own country. (see AMMON.) This country is indeed so desert, that there is no travelling through it without the aid of a compass, or the direction of the stars; and though it was once the thoroughfare for caravans from Barbary and Morocco to Mecca, yet it has been infested with wild Arabs to such a degree, that they are obliged to steer 50 leagues about to avoid being plundered. The French geographers divide the country of Barca into two parts; one called the kingdom, and the other the desert; the former hath, according to their statement, some considerable ports, towns, and villages, and is under the protection of the Porte, governed by a cafi, who is the basha of Cairo, and resides at Tripoli; but for this they have no sufficient authority. According to Saufon and Baudrand, the other part, which extends along the eastern coast, called by them the eastern shore of Tripoli, reaches from the port of Solomon or Solyman, to the gulf of Sydra; but this coast is commonly distinguished by the name of Derna, one of the most considerable of its towns and ports; besides which it has several others, and the ruins of many more, which are now reduced to poor villages. The most remarkable are the cape Raceallino, styled by Ptolemy Cherfoneus, because it forms a peninsula; and the farthest towards Egypt is the town of Angela or Onzela. (see ANGELA.) Between these two, are many others differently placed and named, as the Porto Tabarca, formerly Batrachus, Batracha, and Patriarcha, cape de Lucco or Leco, anciently Promontorium Carylonium, Porto Mefalman, the haven of Salon or Saiona, supposed by some to be the ancient Portus Panormus, and Galinus, and by others the Portus Catabathmus, which our latest geographers place on the most eastern verge of the Barcan coast, next to the confines of Egypt. To which may be added the large valley of Carto Sappires, the ancient Catabathmus, extending quite to Egypt, opposite to the spot where the temple of Jupiter Ammon stood. From these we proceed to Porto Albittene, or the Sultan's port; that of Caguxi, formerly Trifachi; the cape and haven of Raxa, anciently Paratonium; and, lastly, the city of Barca or Barea, which gives name to the whole province, and lies farther inland, on the eastern coast of the gulf of Sydra. This was the capital of the Barcan, and is mentioned by Strabo, Pliny, Scylax, and Ptolemy; and is said by the two former to have occupied the spot on which Ptolemais was afterwards built; but the two latter are of a different opinion.

nion. It seems to have stood to the west of Cyrene, and had a port near the Greater Syrtis. As it was a maritime city, it is most probable that it stood by the port of the Barcæi, and not where Barce stood; more especially as that capital was 100 stadia from the sea, according to Scylax. Herodotus says, that Barca was built by the brothers of Arcefilaus III. king of Cyrene, more than a generation before the beginning of the reign of Cyrus; but it is more probable, that it was of Phœnician, if not of Egyptian or Libyan extraction; for Barca was a Phœnician name, well known in those parts of Africa, as we learn from Silius Italicus, and others. Servius intimates, that its citizens came originally from Carthage, which would lead us to conclude, that Barca, Dido's brother, who attended her into Africa, with some of his countrymen, settled here. It sufficiently appears from Virgil and Silius, that the Barcæi spread themselves over several considerable parts of Libya; and, according to Servius, their metropolis made the greatest figure of any city in this region, except Cyrene. St. Jerom confirms these last authorities, when he asserts that this town was situated in a desert; and that its inhabitants, or at least their descendants, dispersed themselves over several districts, lying as far to the westward as Mauritania, and the eastward as India. The Barcæi learned (says Stephanus) the art of managing horses from Neptune, and of driving chariots from Minerva. The modern kingdom and desert of Barca undoubtedly derived their name from the Barcæi; and we may hence infer, that these people formerly held a considerable rank among the various nations of Libya.

What is the present condition of the towns of Barca, what is their commerce, and how they are governed, we have no authentic documents for ascertaining. The maritime towns are, probably, under the protection of the Porte; but it is not certain whether they are under the government of the basha of Egypt or Tripoli, or they have formed themselves into free states like those of Algiers and Tunis. This however is certain, that the inhabitants of the maritime towns are more civilized than those within land. The first profess Mahometanism, and have imbibed some notions of humanity and justice; but the latter, and especially those of the desert, who have neither religion nor any appearance of worship among them, are altogether brutish and savage, and live wholly upon theft and plunder, like all other wild Arabs. By them this tract, which was before a barren desert, was first inhabited. Destitute and indigent in the extreme, they are said also to be the ugliest of all the Arabs; their bodies being meagre, their faces grim, and aspect fierce and ravenous; their garb, which is commonly stripped from the passengers and pilgrims, tattered with long wearing; whilst the poorest of them want rags to cover their nakedness. They are likewise reported to be resolute and expert robbers and plunderers; but deriving a scanty supply from their own neighbourhood, they are compelled by necessity to extend their excursions as far as Numidia, Libya, and other southern parts, where they commit many atrocious acts of cruelty. So indigent and famished are these Barcans, that they commonly let, pledge, and even sell their children, for procuring the necessaries of life, to the Sicilians, and other neighbouring Christians, from whom they have most of their corn, especially before they set out on any long expedition. The chief towns of Barca are Derna, the capital and residence of the sangaic, Tolometa or Ptolometa, and Grena or Caren. Anc. Un. Hist. vol. xvi. p. 181. Mod. Un. Hist. vol. xv. p. 196, &c.

BARCA, a small port on the coast of Peru, about S. lat. 11° 20', where ships may anchor, but obtain no supply.

BARCALAO, a Spanish word, which the French pronounce *baccala* or *baccaliau*. By this last name the Basques most commonly call the fish which we style cod; and those people call also the island which we call Newfoundland, the isle of *Baccaliau* (*Cod Island*), because of the great plenty of cod caught there. There is, however, a league to the west of that large island, another small one, which is more particularly called *Baccaliau*.

BARCALON, an appellation given to the chief minister of the emperor of Siam, to whom belongs the care of trade both within the kingdom and out of it, the superintendency of the royal magazines, the receipt of the revenues, and the management of foreign affairs.

BARCA-LONGA, a large Spanish fishing-boat, navigated with lug-sails, and having two or three masts. These are very common in the Mediterranean. See BARK.

BARCANI, in *Ancient Geography*, a people of Asia, in the vicinity of Hyrcania. They are placed by M. D'Anville, on the east of the Caspian sea, near one of the mouths of the Oxus.

BARCAROLLA, in *Music*, a kind of song in the Venetian language, sung at Venice by their gondoliers or watermen, in their boats or barks. These airs (says Rousseau) are composed for the common people, and often by the gondolieri themselves. They have so much melody, and such an agreeable accent, that there is not a musician in all Italy who does not pique himself on knowing some of them. The being admitted *gratis* into a gallery appropriated to them in all the theatres, enables gondolieri to form their ear and taste, without trouble or expence, so that they compose and sing their airs, without altering their natural simplicity, in the style and expression of persons not ignorant of the refinements of music. The words of these songs are commonly jocose, and more than natural, like the conversation of those that sing them; but such as the faithful picture of the manners of a people can please, and such as are likewise partial to the Venetian dialect, soon become passionately fond both of the words and music of these airs, chiefly known in England by the title of Venetian ballads, of which travellers into Italy make collections.

The late earl of Leicester, one of the subscribers to the royal academy of music in 1720, used to say, that at the first establishment of operas in England, the nobility and gentry, in imitation of the Venetians, suffered their servants to have admission, gratis, into the upper gallery, with a view to improve the national taste in singing; but instead of profiting or deriving pleasure from this privilege, they became so noisy and insolent, that about 40 years ago, like our first parents, they were driven out of paradise.

We must not forget (says Rousseau) to remark, for the glory of Tasso, that most of the gondolieri know the chief part of his poem "Gierusalemme liberata," by heart, and some the whole; that they pass their summer nights in their gondolas, singing it alternately from bark to bark; that the poem of Tasso is an admirable barcarolla; that Homer only had the honour of being thus sung before him; and that, since his time, no other Epic poem has been thus distinguished.

BARCAROTA, in *Geography*, a town of Spain, in Estramadura, 4 miles from Almendrolejo.

BARCE, in *Ancient Geography*. See BARCA.

BARCE, a town of India, built by Alexander, on the sea-coast, in memory of his exploits, and where, according to Justin, he erected altars.

BARCELONA, in *Geography*, a rich and strong city and

and sea-port of Spain, in the province of Catalonia, of which it is the capital, and the see of a bishop, suffragan of the archbishop of Taragona. It was originally founded by Hamilcar Barca, the father of Hannibal, and from him called "Barcino," about 250 years before Christ. It was reduced by the Romans, and continued subject to them till the kingdom of Spain was overrun by the Goths and Vandals, and afterwards by the Saracens and Moors. At the beginning of the ninth century it was possessed by the Moors, under the government of Zade. This governor having abused the clemency of Charlemagne, and by his perfidious behaviour provoked his son, Lewis king of Aquitaine, Barcelona was invested, and the generals who were intrusted with the command of the siege had orders not to abandon it till Zade was delivered into the hands of Lewis. The Moor made an obstinate resistance; but finding that it was impossible to preserve the city any longer, after a defence of many months, he determined to throw himself upon the emperor's mercy, and was condemned to perpetual exile. At length, however, the city surrendered, and the king of Aquitaine appointed one Bera, count of Barcelona. The city continued subject to him and his successors, who were distinguished by the title of "Counts of Barcelona," from the year 802 to 1131; when it was united to the crown of Arragon by the marriage of Don Raymond V. count of Barcelona, with Donna Petronilla the daughter of Don Ramiro the monk, and heirs of Arragon. In consequence of the revolt of the Catalonians, in 1465, Barcelona was besieged by Don Juan II. king of Arragon, in 1471. The siege was prosecuted for a considerable time with vigour, but without effect; however, in 1472, it capitulated on its own terms; and the king, upon his public entry into the city, confirmed all its privileges. In 1640, the Catalans, having shaken off the yoke of the Spaniards, called in the French to their succour; and they continued masters of the capital till 1652, when, after a siege of fifteen months, it surrendered to Don Juan of Austria. In 1697, it was again taken by the French under the command of the duke of Vendôme, but restored the same year to the Spaniards by the peace of Ryswick. Although the inhabitants of Barcelona had taken the oath of fidelity to the king of Spain, Philip V. and received from him a confirmation of their privileges, they invited the English and Dutch, and the governor was obliged to surrender the town to the allies in 1705, when Charles, afterwards emperor, was received and proclaimed king. In the following year, Philip, assisted by the French, assailed the city, and took the fortress of Montjoui; but the fleet of the allies advancing to the relief of the besieged, he was compelled to abandon the enterprise and to retire from the place, May 12th 1706. By the treaty of Utrecht, in 1713, the troops of the emperor evacuated Catalonia; but the inhabitants of Barcelona persisted in their revolt, and would not acknowledge Philip for their king. Accordingly they suffered blockade for a year, which was followed by a terrible bombardment; and at length, after a siege of sixty-two days, from the opening of the trenches by the duke of Berwick, the town was taken by assault on the 11th of September 1714. By the moderation of the conqueror, the city was saved from pillage, but the inhabitants were deprived of their privileges; they have since, however, been re-established, and in 1715 a citadel was erected to keep them in awe.

Barcelona is now one of the largest and handsomest cities in Spain, and is reckoned the third most considerable city in the kingdom. It is situated on a plain by the sea-side, open to the south-east, but protected by hills on the north and west, so that it affords a healthy and delightful residence; however it is subject to a fog brought on by the east wind.

The city is furrounded by a good brick-wall, round which is another, with fourteen bastions, horn-works, ramparts, and ditches. The ramparts are high and spacious, and a great number of carriages may be seen every evening driving upon them for pleasure. The city is divided into two parts; the old and the new, which are separated from each other by a wall and a large ditch. The streets are narrow and crooked, and the churches are rather rich than beautiful. Barcelona contains several considerable edifices: that called the Terzana, or the arsenal, is of large extent; and a prodigious gallery, containing twenty-eight forges, has been erected in it within a few years. The other most remarkable buildings are the cathedral, adorned with two high towers, the church of Notre Dame, the palace of the bishop, the exchange, the palace of the governor, that where the nobility of the country assemble, called "La Casa de la Deputation," and that of the inquisition. The hospicio contains about 1400 industrious poor; and in the house of correction are sometimes found women of rank, who have been guilty of drunkenness, or other low vices. The harbour is spacious, deep, and secure, and defended on one side from the winds by a mountain called Montjoui, which rises in the middle of the plain near the city, runs into the sea in the form of a promontory, is covered with vineyards, gardens, and groves of trees, and a strong fort for defending the city, and furnishes a quarry of fine hard free-stone; and on the other side by a large mole; having a light-house with a small fort and garison at the extremity. Into this harbour 1000 vessels are supposed to enter during peace, and of these 500 are Spanish, 120 French, 100 English, and 60 Danes. Barcelona is a place of great trade, on account of the convenience of its harbour; although none but small vessels can enter within the mole. Its chief manufactures are silk, cotton, and wool, and excellent fire-arms and cutlery: its chief imports are corn, fish, and woollen goods; and its exports wine, brandy, cloth, and leather. Silks from Lyons, stockings from Nismes, several kinds of stuffs and cottons although they are prohibited, and particularly dried cod, an article for which Spain is said to pay annually to the English three millions of piastres, pass into Catalonia through this port. About twenty years ago, a very large cannon foundery was established in this city, under the direction of M. Maritz, a Swiss; and it has several glass-houses. The inhabitants are industrious and active, and their number is said to exceed 100,000; they are hospitable to strangers; the women are as handsome as any in Spain, lively in their conversation, and less restrained in their conduct than in other parts of the country. Barcelona was erected into a county by Charlemagne, and became an independent sovereignty in the year 873 or 884. The king of Spain is called the count of Barcelona. The diocese contains 213 parishes, besides 8 in the city. It is distant 13 leagues E. N. E. from Taragona, and 92 E. N. E. from Madrid. N. lat. 41° 26'. E. long. 2° 13'.

BARCELONETTA, a town of France, and principal place of a district in the department of the Lower Alps. It anciently belonged to Piedmont, and was ceded to France by the treaty of Utrecht in 1713. It is situated on the right bank of the Ubaye, in a valley of excellent pasturage, 4 leagues S. of Embrun, and 8½ N. N. E. of Digne. N. lat. 44° 23'. E. long. 6° 40'.

BARCELONETTA, or *Cumanyotto*, a town of South America, in the country of Terra Firma, and principal place of a district in the province of Cumana.

BARCELONNE, a town of France, in the department of the Gers, and chief place of a canton in the district of Nogaro, seated on the Adour, containing about 2000 inhabitants;

bitants; 3 leagues S.W. of Negroo, and 9 $\frac{1}{2}$ W.N.W. of Mirande.

BARCELORE, a sea-port town of the East Indies, on the coast of Malabar, between Goa and Mangalore, in a district ceded to the British by the treaty of 1799. It has a good harbour, and the Dutch had formerly a factory in this place, which carried on a considerable trade in pepper. N. lat. 13° 36'. E. long. 74° 45'.

BARCELOS, a town of Portugal, with the title of a duchy, in the province of Entre Duero e Minho, 10 miles far from the sea, on the river Cavado, 8 miles W. of Braga. N. lat. 41° 20'. W. long. 7° 0'.

BARCES, or BARCHES, were formerly a kind of ship guns, not unlike fakers, only shorter, thicker in metal, and wider bored.

BARCHIN, in *Geography*, a town of Persia, in the province of Kerman, 120 miles S. E. of Sirgian.

BARCHOCHEBAS, or CAZIBA, in *Biography*, a false Messiah of the Jews, who taking advantage of the animosity excited among his countrymen by the profanations of the emperor Adrian, when he founded his new city of Bethia on the ruins of Jerusalem, about the year 134, assumed the name of *Barchochab*, or *child of the Star*, in allusion to a prophecy of Balaam (Numb. xxiv. 17.) and pretended to be the long-expected deliverer of his nation. He chose for his precursor the famous Akiba; and collecting together an army of 200,000 men from among the banditti who then infested Judaea, took possession of the strong town of Bither, called by St. Jerom Bethoron, between Caesarea and Diocopolis, which he fortified as the place of his retreat and the capital of his newly-projected kingdom. Here he was anointed king, and caused money to be coined in his own name, by which he proclaimed himself the Messiah and prince of the Jewish nation. However he deferred declaring war against the Romans, till Adrian had quitted Egypt, so that it did not break out till the 17th year of that emperor's reign. Adrian seems at first to have neglected this new revolt; but when he perceived that it was likely to become formidable, he sent Tinnius Rufus with a strong reinforcement to quell it. This force being insufficient to restrain the depredations of these banditti, who massacred all the Romans and Christians that fell in their way, Julius Severus was recalled from Britain, and sent at the head of an army against the impostor. This general laid siege to Bither, which was resolutely defended, till Barchochebas was slain. The town was then carried by storm, and this event, which, according to Eusebius, happened in the 18th year of Adrian, was followed by a most dreadful slaughter of the Jews. Crevier's Rom. Emp. vol. vii. p. 188, &c. Bagnage, Hist. des Juifs. l. vii. c. 12. Mod. Un. Hist. vol. x. p. 437. &c. See AKIBA.

BARCHUL, in *Geography*, a town of Spain, in the country of Granada, five leagues from Guadalix.

BARCHUSEN, or BAREHAUSEN, JOHN CONRADE, in *Biography*, a learned physician and chemist, was born at Horne in the county of Lippe, in 1666. After a liberal education, and a course of travelling through the principal cities of Germany with a view to his improvement in pharmacy and chemistry, he became physician to the Venetian general in his expedition to the Morea in 1694; and on his return settled at Utrecht, where he obtained permission to teach chemistry, in which employment he continued till the time of his death in 1717. His character was distinguished by integrity and zeal for public good, as well as by indefatigable assiduity in the pursuit of knowledge; without possessing any very extraordinary share of genius or solidity of judgment. His works are, "Synopsis Pharmaceutica,"

Frankf. 1690, and Utrecht, 1696, 8vo.; "Pyrotophia," Leyd. 1698, 4to. enlarged and published at Leyden in 1771, under the title of "Elementa Chemiæ" &c. "Acroamant ad Jatrochymiam & Physicam Speculantia," Utr. 1703, 8vo.; "Historia Medicinæ," Amst. 1710, 8vo.; published with enlargements under the title of "De Medicinæ ortu et progressu Dissertationes," &c. Utr. 1723, 4to. in which work an account is given of all the sects and theories of medicine from the earliest times to the author's own age, but with less accuracy, especially in relation to the ancient writers, than those of Le Clerc and Freund; "Synopsis Pharmaceuticæ," Leyd. 1712, 4to; "Compendium Ratiocinii Chemicæ," Leyd. 1712, 4to; "Collecta Medicinæ Præcticæ Generalia, et Dialogus de optima Medicorum secta," Amst. 1715, 8vo. Haller Bib. Med. Pract.

BARCINO, in *Ancient Geography*, a town of Hispania Tarraconensis, and capital of the Lactani; now BARCELONA.

BARCLAY, PARCLEY, or BARCLAY, ALEXANDER, in *Biography*, an elegant British writer of the 16th century, was a native either of England or Scotland but probably of the latter country. About the year 1495, he came to Oriel college, Oxford, and having distinguished himself by his parts and learning, he travelled on the continent and acquired a competent knowledge of the languages spoken in Holland, Germany, Italy, and France. On his return to England, he became one of the priests of St. Mary Ottery in Devonshire, and afterwards a monk of the monastery of Ely. After the dissolution of this monastery in 1539, he was presented successively to several livings, the last of which were those of Baddow-Magna in Essex, and of Allhallows in London. He was honoured with the degree of doctor in divinity. He died at a very advanced age at Croydon in Surry, in June 1552. Different accounts have been given of his character. Bale, the protestant, treats his memory with indignity, and charges him with being a scandalous adulterer, whilst he led a single life; but Pitts, the papist, assures us that he directed his studies to the service of religion, and employed his time in reading and writing the lives of the Saints. These accounts, however, are not altogether incompatible. As an improver of English literature, his merits are acknowledged; and his industry in enriching our language with many translations, written in a style more pure and fluent than that of his contemporaries, entitles him to grateful commemoration. Some of the principal of his works, of which there is no complete catalogue, are the "Miseræ Carialium," or "Eclogues on the Miseries of Courtiers," compiled by Æneas Silvius; the "Eclogues of Baptist Mannan;" the "Castle of Labour," from the French; a treatise "Of Virtues," by Mancini; several "Lives of Saints;" the "Jugurthine war" of Sallust; a "Treatise against Skelton," who was poet laureat, and a great enemy to priests; and the most popular of all his works, the "Navis Stultifera" or "Ship of Fools," which is a free translation, with considerable additions, from a work under the same title, by Sebastian Brantius; this is a satirical work, adorned with many pictures printed from wooden cuts; it passed through several editions, and was first printed at London by Richard Pynson, in 1509, in small folio, again in 1519, and in 4to. in 1570. Gen. Dict. Biog. Brit.

BARCLAY, WILLIAM, a learned civilian, was born in Aberdeenshire in 1541, and descended from one of the best families in Scotland. After the captivity of Mary queen of Scots, by whom he was favoured, he retired to France about the year 1573, and then by close application became a proficient in the knowledge of the civil law, so that he obtained a professorship in that science in the university of

Ponta-

Pontamousson, founded by the duke of Lorraine; he was also appointed by this duke counsellor of state, and master of requests. In 1591, he married a lady of Lorraine, by whom he had a son, who was the cause of his contest with the Jesuits, by whose influence he was reduced to the necessity of quitting Lorraine. He then came to England, and was offered a place in the council of James I. with a considerable pension, on condition of his embracing the established religion; but declining the offer, he returned to France, and accepted the professorship of civil law in the university of Angers, where he taught for some time with reputation. Here he died as some say in 1605, according to others in 1609, or 1611. The chief of his works are "De Regno et Regali potentate, adversus Buchananum, &c." published at Paris in 1600; "De potestate Papæ, an et quatenus in reges et principes seculares jus et imperium habent." Francof. 1609, 1612, 1629. Harlow. 1612, 8vo. Lond. in English, in 1611, 4to; "A Commentary upon the title of the pandect: *de rebus creditis et de jurjurando*;" Paris, 1605, 8vo.; and "Præmetia in vitam Agricola;" Paris, 1599, 2 vols. 8vo. Gen. Dict. Biog. Brit.

BARCLAY, JOHN, the son of the preceding, was born at Pontamousson in 1582, and distinguished himself betimes as a proficent in polite literature. The Jesuits wished him to enter into their society; but his father incurred their resentment by preventing it, and taking him to England, at the beginning of the reign of James I. He had already, viz. in 1601, published a commentary on the Thebaid of Statius. He also presented to James, a Latin poem upon his coronation; and in 1602, published the first part of his "Satiricon Euphormionis," which was dedicated to the king. He accompanied his father to Angers, with whom he continued till the death of the latter, and then removed to Paris. In 1606, he came over to England, where he obtained considerable employments under king James, and was made gentleman of the bed-chamber. He is said to have assisted this prince in a controversial work, which occasioned some unfounded suspicions of his orthodoxy. Having finished his "Euphormio," he published an apology for it in 1610. Upon his return to Paris, he printed in 1612, a work intitled "Pietas," being a vindication of a performance of his father against the power arrogated by the popes over crowned heads, which had been attacked by Bellarmine. Nevertheless, he was invited to Rome by Paul IV., and resided there during the latter part of his life, carested by Bellarmine, and possessing some lucrative employments, in return for which he wrote a work of controversy, intitled, "Parænesis ad Sectarios." Whilst he was employed in superintending the first edition of his principal work, intitled the "Argenis," he died of the stone at Rome, in 1621. The disposition of Barclay was of a melancholy cast; his mornings were uninterruptedly employed in study, and the afternoons were devoted to his garden. His reputation, both as a scholar and a writer, was extremely high in his own times; but his works were not of a nature, calculated to command lasting attention. His Latin style was much admired by some, and severely censured by others. Petronius was his model, but he somewhat partakes of the florid affectation of Apuleius in his prose, and of the bombast of Lucian in his verse. His "Euphormio," and "Argenis," both works of invention, passed through several editions in various languages. The latter is a kind of political allegory, exhibiting a picture of the vices and revolutions of courts, with real characters under fictitious names. It displays great ingenuity and learning, and abounds with lively imagery and elevated sentiments, but with too much parade. It was

read with avidity whilst the subjects were recent: and a translation of it in English by a lady appeared in 1772, without attracting much notice. Gen. Dict. Biog. Brit.

BARCLAY, ROBERT, the famous apologist for the Quakers, was the descendant of an ancient family in Scotland, and the son of colonel David Barclay of Maithers. He was born at Goslonstown in the shire of Murray, in 1648, whether his father had retired, after quitting the army; and was sent for education to his uncle at Paris, who was at that time principal of the Scots college. Pains were taken to proselyte him to the catholic religion; and he acknowledged that they were not altogether unsuccessful. He returned home, however, in his 17th year, and was distinguished by his accomplishments in literature, and particularly by his knowledge of the Latin and French languages. At home he extended his acquaintance, by diligent application, with the Greek and Hebrew; and being of a grave disposition, directed his inquiries towards theological subjects. His father, having in 1666 become a convert to quakerism, was soon followed by his son; whose zeal, though generally under the control of a sedate temper and sound judgment, was not altogether free from enthusiasm; for he conceived himself obliged by divine command to pass through the streets of Aberdeen clothed in sackcloth and ashes, and he actually yielded to this impulse. But he served the cause, to which he was attached from conviction, much more effectually by his powers of reasoning in its defence. His first publication to this purpose, intitled "Truth cleared of calumnies," &c. was a reply to a work of W. Mitchell, a preacher near Aberdeen, and dated at his father's house at Urie, in 1670. This was followed by an appendix and additional treatise, exhibiting a considerable portion of controversial acrimony, but it had the effect of silencing his antagonist. In 1673 he published with a view of conciliating the good opinion of Protestants, a systematic exposition of the doctrines of his sect, under the title of "A Catechism and Confession of Faith, approved of and agreed to by the general assembly of the Patriarchs, Prophets, and Apostles, Christ himself chief Speaker in and among them," &c. The design of this work was to prove, that Quakerism was the perfection of the reformed religion, and that Protestants, as they receded from it, were so far inconsistent with themselves, and approached to Popery. His fundamental principle was, that the scriptures alone were to be regarded as the foundation of faith, and that Christians ought to receive no doctrines which were not capable of being proved by the express words of scripture. This work excited very general attention, and removed many prejudices that were entertained against the society. His next treatise, intitled "The Anarchy of the Ranters and other Libertines, the Hierarchy of the Romantics, and other pretended churches, equally refused and refused," &c. was intended to mark the distinction between the rationalists of his sect, and the enthusiasts; but some sentiments concerning church discipline, which it contained, involved him in disputes with some of his own brethren, and drew upon him attacks from some members of the university of Aberdeen, and from other quarters. He persisted, however, in his endeavors for forming a clear, methodical, and rational system of Quakerism; and in the year 1675, he was diligently employed in composing the most famous of all his writings, which is his "Apology for the true Christian divinity, as the same is held forth and preached by the people in scorn called Quakers." This was introduced by his "Theses Theologicæ," written in various languages, and addressed to the clergy of all denominations throughout Europe, requesting their examina-

tion and judgment. Two copies of the "Apology" were transmitted to each of the ministers plenipotentiary then assembled at the congress of Nimeguen. It was printed in 1676, at Amsterdam; and two years after, the author published an English translation of it. It was also translated into other languages, and excited very general attention. The "Apology" is a learned, scholastic, methodical performance; and it is regarded as the first authority for the principles of the sect. The society derived considerable reputation from it; and whilst it contributed to remove prejudices against this sect both at home and abroad, it gave them a respectable rank among the reformed churches. The dedication is no less remarkable than the apology itself. It is addressed to king Charles II.; and speaks to him in so plain and forcible a manner respecting the events of his own life, and pleads the cause of religion, and of the author's own society, with such a manly spirit, that it has ever been admired as a model in its kind. Let the following passage serve as a specimen: "Thou hast tasted of prosperity and adversity; thou knowest what it is to be banished thy native country, to be over-ruled as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is both to God and man." This address did not avail, as Voltaire asserts, to restrain the persecution which then raged against the Quakers; for Robert Barclay himself, after his return from Holland and Germany, which he visited in company with the famous William Penn, was, in 1677, imprisoned in Aberdeen, together with his father and many other Quakers, at the instigation of Sharp archbishop of St. Andrew's, with whom he remonstrated by an excellent letter on the occasion. By the interposition of Elizabeth the princess palatine of Rhine, who respected the Quakers and corresponded with both Penn and Barclay, he was soon liberated; and he even acquired the favour of the court, so that in 1679, he obtained a royal charter for erecting his lands at Urie into a free barony. In 1682, he was elected governor of East Jersey, in North America, by the proprietors of the province; but he declined accepting the appointment, and was satisfied with naming a deputy governor. Whilst he was in prison at Aberdeen, in 1677, he published a treatise on "Universal Love," intended to shew that this principle prevailed more in his church than in any other. In the same year he addressed a Latin letter to all "the ambassadors and deputies of the Christian princes and states, met at Nimeguen to consult the peace of Christendom," urging them to promote that good work, and pointing out the true causes of war, and its incompatibility with Christian principles. He had also written, in 1676, a Latin letter concerning "the Possibility and Necessity of an inward and immediate Revelation," to Adrian Paets, a person of distinction in Holland; and in 1686 this letter was translated into English and published. This was the last, and has by many members of the society, been reckoned among the most important of his performances. His time was very much occupied in journales for the benefit of the society, with a view both of promulgating its doctrines, and protecting its members from oppression. Barclay and Penn were on terms of intimacy with James II.; who, sensible that he and his party needed toleration, affected to be the great patron of liberty of conscience. The non-resisting principles of the quakers in civil matters, might probably give him a predilection for their religious opinions above those of other Protestants. Barclay was engaged in a private conference with the king in the year 1688, just as the wind became fair for bringing over the prince of Orange, and on that occasion urged his majesty to make some concession for

satisfying his people; but his advice was of no avail. Robert Barclay did not long survive the revolution. He died, after a short illness, in his house at Urie, in October 1690, in his forty-second year, leaving seven children, all of whom were living fifty years afterwards. The moral character of this eminent person corresponded to the great employment of his life, which was that of promoting what he conceived to be the cause of religious truth. He was amiable and respectable; nor did the gravity of his pursuits infuse any rigour or formality into his conversation and manners. He governed his house with great prudence and discretion, and preserved a serene mind under all the changes of his fortune. *Biog. Brit. Gen. Biog.*

BARCLAY Fort, in *Geography*, is the west point of the entrance into English harbour, on the south side of the island of Antigua; the east point also has a battery, from which it is distant only about 300 yards.

BARCONE, in *Navigation*, a short broad vessel, of a middle size, used in the Mediterranean for the carriage of corn, wood, salt, and other provisions, from one place to another.

BARD, is used in the *Culinary Art*, for a broad slice of Bacon used to cover fowls before they are roasted, baked, or otherwise dressed.

BARDA, or **PAETHA**, in *Geography*, a town of Germany, in the circle of Upper Saxony and circle of Leipsick, 2 miles S.W. of Grimma.

BARDANA, in *Botany*. See **ARCTIUM**.

BARDANA, in the *Materia Medica*. See **ARCTIUM Lapp.**

BARDANÆ, in *Entomology*, a species of **CURCULIO**, of a cylindrical form, downy, greyish; anterior legs elongated. About the size of *C. paraplecticus*, and not unlike it in appearance. Inhabits Europe.

BARDARIoTÆ, in *Antiquity*, were a kind of ancient guard attending the Greek emperors, armed with rods, wherewith they kept off the people from crowding too near the prince, when on horseback. Their captain, or commander, was denominated *primivergius*. The word was probably formed from the *barde* or houlings on their horses.

BARDE. See **BARBE**.

BARDED, in *Heraldry*, is used in speaking of a horse that is caparisoned.

He bears sable, a *cavalier d'or*, the horse *barded*, argent.

BARDELLE, in the *Manege*, denotes a saddle made in form of a great fiddle, but only of cloth stuffed with straw, and tied tight down with packthread, without either leather, wood, or iron. *Bardelles* are not used in France; but in Italy they trot their colts with such saddles; and those who ride them are called *cavalcadours*, or *scozons*.

BARDESANISTS, in *Ecclesiastical History*, a sect thus denominated from their leader, Bardesanes, a Syrian of Edessa in Mesopotamia, in the second century. Bardanes was a man of acute genius and profound erudition, and wrote several works which procured him reputation. He was eloquent in the Syriac language, and well acquainted with the Greek. His thirst for knowledge induced him to travel into the east, in order to converse with the brachmans and other philosophers of that country. He was held in high estimation by Abgarus, who reigned in Edessa from the year 152 to 187. A work written by him, "upon Destiny," against Abydas the astrologer, was valued by the ancients; and a fragment of it is quoted by Eusebius, in his *Prep. Evang.*

Bardesanes adopted the oriental philosophy concerning the two principles; maintaining that the supreme God is free from all evil and imperfection, and that he created the world and its inhabitants pure and incorrupt; that in process

process of time the prince of darkness, who is the fountain of all evil and misery, enticed men to sin; in consequence of which, the supreme God permitted them to be divested of those ethereal bodies with which he had endued them, and to fall into sluggish and gross bodies formed by the evil principle: and that Jesus descended from heaven, clothed not with a real but aerial body, in order to recover mankind from that body of corruption which they now carry about them; and that he will raise the obedient to mansions of felicity, clothed with aerial vehicles, or celestial bodies. It is said that Bardesanes at length renounced the more chimerical part of his system. Eusebius denied that he ever returned to the Catholic faith. His sect subsisted for a long time in Syria, to which his 150 hymns written in elegant Syriac very much contributed; as they also did to the propagation of his opinions. Mosheim's *Eccle. Hist.* vol. i. p. 220. Lardner's Works, vol. ii. p. 299, &c.

BARDEWICK, in *Geography*, a town of Germany, in the circle of Lower Saxony, on the Ilmenau, supposed to be one of the most ancient towns in Germany. It was in a very prosperous state, and the see of a bishop in 1189, when Henry the Lion, duke of Saxony and Brunswick, took and razed it to the ground, because the inhabitants would not acknowledge him after he had been proscribed by the emperor Frederick I. The bishoprick was then removed to Verden; and the city of Lüneburgh received the advantages of trade and population; 4 miles N. of Lüneburg.

BARDEWISCH, a town of Germany, in the circle of Westphalia, and county of Delmenhorst; 6 miles N. of Delmenhorst.

BARDI, a town of Italy, in the Parmesan, seated on a rock near the small river Ceno, and capital of a marquisate, to which it gives name; 26 miles W. of Parma.

BARDIN, a town of Persia, in the province of Segestan, 30 miles W.S.W. of Zareng.

BARDIS, a town of Egypt, and residence of a scheid, whose authority extends a considerable way along the Nile, 6 miles south of Girgê.

BARDISTAN, *CAPP*, lies on the coast of Persia, in the Indian ocean. N. lat. 28° 0'. E. long. 52° 0'.

BARDO, a town of Piedmont, in the duchy of Aosta, seated on the Doria Baltea; 17 miles S.E. of Aosta.

BARDONACHE, a town of Piedmont, in a valley, to which it gives name; 10 miles north of Sezanne, and 6 W.N.W. of Exilles.

BARDOP, a river of England, which runs into the Read, 6 miles N.W. of Ellfsdon, in Northumberland.

BARDS, **BARDI**, in *Antiquity*, ancient poets among the Gauls and Britons, who described and sung in verse the brave actions of the great men of their nation; with design to inculcate and recommend virtue, and even sometimes to put an end to the difference between armies at the point of engagement.

Bochart derives the word from *parat*, to sing. Camden agrees with Festus, that *bardus* originally signifies a singer; and adds, that the word is pure British. Others derive the word from *Bardus*, a druid, the son of Dryis, and the fifth king of the Celts.

Amidst this uncertainty with regard to the etymology of the appellation *bards* or *beird*, we may add that some have derived it from *bar*, which signifies *fury*, and which bears, without doubt, some analogy to that poetic fury or enthusiasm with which the poets fancied themselves, or might feign to be inspired. Among the Welch, we are told by others, *bard* is preserved as an indigenous term, having an abstract signification, and denoting one that makes conspicuous, or causes to be revealed. By another

author we are informed that the word *bard* being a primitive noun, neither derived nor compounded, it can neither be traced to its root, nor resolved into its parts. It signified one who was a poet by his genius and profession, and who employed much of his time in composing and singing verses on various subjects and occasions.

The bards, it is said, differed from the *druids*, in that the latter were priests and teachers of the nation, but the former only poets and writers.

Larrey, Bodin, and Pasquier, indeed, will have the bards to have been priests, as well as philosophers: and Cluverius, orators too; but without much foundation in antiquity.— Strabo divides the sects of philosophers among the Gauls and Britons into three, viz. the druids, bards, and evates. The bards, adds he, are the singers and poets; the evates, the priests and natural philosophers; and the druids, to natural philosophy add also the moral. Hornius however reduces them to two sects, viz. bards and druids; others to one, and make a druid a general name, comprehending all the others. Cluverius will have it, that there were bards also among the ancient Germans; because Tacitus makes mention of their songs and poems, which contained their history. Some have distributed the ancient British poets into two classes; the first class comprehending their sacred poets, who composed and sung their religious hymns, and were called in Greek *Enbates*, in Latin *Vates*, and in their own language *Fuids*; the second comprehending all their secular poets, “who sung of the battles of the heroes, or the heaving breasts of love,” according to the description of Ossian, and they were called bards. The principal business of these bards was to celebrate the praises of the gods and departed heroes, in odes and verses, and to sing them to their harps, at their religious assemblies, public festivals, and private entertainments. These men were, in fact, the heralds, the chronologers, and the historians, as well as the poets of the land, for they kept up the memory of illustrious transactions, and, by their compositions, which tradition handed down to posterity, they transmitted from age to age the names and characters of patriots and warriors. It is remarkable that such a class of persons subsisted in almost all nations. They derive their origin from remote antiquity, and were ever held in high estimation. Mankind have been early led to poetical compositions. Agreeable sounds strike at first every ear, but poetry was necessary to give those sounds a lasting effect. Verse has therefore been made use of to preserve the memory of remarkable events and great actions. The religious ceremonies of nations, their manners, and rural labours, were also recorded in numbers. Hence it was that Greece could boast of a Homer, a Hesiod, and of other poets, some ages before an historian had written in prose. Amongst the Gauls also, and other Celtic nations, there were poems composed on various subjects from the earliest ages. Diodorus Siculus is the first author among the ancients, who mentions the bards as the composers of verses which they sung to the sound of an instrument not unlike a lyre (l. v. § 31.). Ammianus Marcellinus informs us (l. xii. c. 9.), that the bards celebrated the brave actions of illustrious men in heroic poems, which they sung to the sweet sounds of the lyre. This account of these Greek and Latin writers is confirmed by the general strain, and by many particular passages of the poems of Ossian. “Beneath his own tree, at intervals, each bard sat down with his harp; they raised the song and touched the string, each to the chief he loved.” But this union between poetry and music did not subsist very long, in its greatest strictness, perhaps, in any country. The musicians soon became very numerous, and those of them who had not a genius for com-

posing verses of their own, assisted in singing the verses of others to the music of their harps. Many of those songsters, or parasites (as Athenæus, l. vi. c. 12. calls them), which the Celtic princes took with them when they went to war, were mere musicians, and the songs which they sing were composed by those among them who had a poetical genius, and were called bards. Ossian, however, excelled as much both in vocal and instrumental music as he did in poetry, and he seems to have had no idea of playing on an instrument without singing at the same time. Whenever his bards touch the strings, they always raise the song.

The bards constituted one of the most respected orders of men in the ancient British states; and many of the greatest kings, heroes, and nobles, esteemed it an honour to be enrolled in this order. They enjoyed, by law and custom, many honourable distinctions and valuable privileges. Kings and princes made choice of bards to be their bosom-friends and constant companions; indulged them with the greatest familiarity, and gave them the most flattering titles. Their persons were held sacred and inviolable; and the most cruel and bloody tyrants dared not to offer them any injury. The bards, as well as the druids, were exempted from taxes and military services, even in times of the greatest danger; and when they attended their patrons in the field, to record and celebrate their great actions, they had a guard assigned them for their protection. At all festivals and public assemblies they were seated near the person of the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bard less lucrative than honourable. For, besides the valuable presents which they occasionally received from their patrons, when they gave them uncommon pleasure by their performances, they had estates in land allotted for their support. Nay, so great was the veneration which the princes of these times entertained for the persons of their poets, and so highly were they charmed and delighted with their tuneful strains, that they sometimes pardoned even their capital crimes for a song. It may be reasonably supposed that a profession, which was so honourable and advantageous, and to which were annexed so many flattering distinctions and desirable immunities, would not be deserted. Accordingly, the accounts we have of the numbers of the bards in some countries, particularly in Ireland, are hardly credible. In the poems of Ossian we often read of 100 bards belonging to one prince, singing and playing in concert for his entertainment. Every chief bard, who was called *Allan Redan*, or doctor in poetry, was allowed to have 30 bards of inferior note constantly about his person; and every bard of the second rank was allowed a retinue of 15 poetical disciples. But it is probable that the bards of Britain and Ireland were not so numerous at an early period as they became afterwards; nor were they then guilty of those crimes by which they at length forfeited the public favour. In this most ancient period, the British bards seem to have been in general men of genius and virtue, who merited the honours which they enjoyed. Though the ancient Britons of the southern parts of this island had originally the same taste and genius for poetry with those in the north, yet none of their poetical compositions have been preserved; and this may be easily accounted for. After the provincial Britons had submitted quietly to the Roman government, yielded up their arms, and had lost their free and martial spirit, they could take little pleasure in hearing or repeating the songs of their bards, in honour of the glorious achievements of their brave ancestors. The Romans too, if they did not practise the same barbarous policy which was long after practised by Edward I. of

putting the bards to death, would at least discourage them, and discountenance the repetition of their poems for very obvious reasons. These foes of the song being thus persecuted by their conquerors, and neglected by their countrymen, either abandoned their country or their profession; and their songs, being no longer heard, were soon forgotten. But so natural was a taste for poetry to the original inhabitants of this island, that it was not quite destroyed by their long subjection to the Romans, but appeared again in the posterity of the provincial Britons, as soon as they recovered their martial spirit, and became a free, brave, and independent people. Nennius, who wrote in the ninth century, and in the reign of prince Marvyn, is the first of the British historians who mentions the bards. He says, that *Tallharian* was famous for poetry; that *Aneurin* and *Taliesin*, *Llywarch-hen* and *Chian*, flourished in the 6th century. Of these bards, the works only of three are extant; those of *Aneuryn*, *Taliesin*, and *Llywarch-hen*. Besides the bards already mentioned, there were others who flourished during this period; of whom the most eminent was *Merdulin Wyllt*, who composed a poem called *Afallenau*, or the orchard. From the sixth to the tenth century it is difficult to meet with any of the writings of the bards, owing probably to the devastations of war, and to the civil dissensions among the Welsh.

Such was the respect in which the bards were held, that by a law of *Howel Dha*, whoever struck any one of this order must compound for the offence by paying to the party aggrieved one-fourth more than was necessary to be paid to any other person of the same degree.

The election of the bards was made every year, in an assembly of the princes and chieftains of the country, in which they were assigned precedence and emolument suitable to their merit; but the bard most highly distinguished for his talents was solemnly chaired, and had likewise a badge given him of a silver chain. This congress of the bards was usually held at the royal residence of the prince of Wales; the sovereign himself presiding in that assembly. The bards, properly so called, were distinguished from the *Druids* and *Eubates* or *Ovates*, by the colour of their dress; they were clad in sky-blue garments, whilst the *Druids* wore white, and the *Ovates* green. Their disciples were arrayed in variegated garments of these three colours united. They held their meetings in circles of unwrought stones, astronomically placed as indexes of the seasons, in the open air, and when the sun was above the horizon, or as they expressed it, *in the face of the sun, and in the eye of the light*. They had four principal meetings in the course of the year. The first was on the winter solstice, called *Alban Ariban*, which was the beginning of their year; the second on the vernal equinox, or *Alban Eilir*; the summer solstice, or *Alban Herin*, was the third; and the autumnal equinox, or *Alban Elwed*, was the fourth solemn convention.

It appears, upon a close examination of its principles, that one of the primary intentions of bardism was, that it should be a regular system for preserving authenticated records and various kinds of knowledge in the national memory, as it were, by means of oral tradition. And, in order that nothing should have currency without due consideration, whatever was intended to be received into such a public record, whether the historical and aphoristical triad, or the didactic song, was always laid before the grand meetings. There it was discussed with the most scrutinizing severity; if then admitted, it was re-considered at the second meeting; if then approved of, it was referred to the third meeting; and being approved of by that, it was ratified or confirmed; otherwise it was re-

ferred to the triennial supreme convention for ultimate consideration. At this national meeting, all that had been confirmed at the provincial assemblies were also recited; and the disciples, who there attended from every province, were enjoined to learn them, in order that they might become as widely diffused as possible. What was thus solemnly sanctioned was to be recited for ever afterwards, annually at least, in addition to the former bardic traditions, in the secondary meetings of districts, and also at one or other of the four grand meetings. Such being the bardic establishment, by which tradition became formed into a well-combined science, we may rely on its triads for the best illustration of its principles.

The three cultivators of song and imagination among the nation of the *Cyrry* were *Cwyryon Garbhellon*, who was the first in the world that composed poetry; *Ihu* the mighty, who first applied poetry to preserve memorials and composition; and *Tydain Tá! Aeron*, or *Tydain father of the muse*, who first reduced poetry to an art, and established rules for composition. And from what those three persons executed, originated bards and bardism, as constituted with privilege and custom by the three institutional bards, namely *Plenyryz*, *Alon*, and *Gwron*. They established the privileges and customs which appertain to bards and bardism, and therefore they are called the three institutors. Nevertheless there were bards and bardism before their time; but they were not under the regulation of inviolable tranfit; and they had neither privileges nor customs, except what were obtained through civility and courtesy, under the protection of the country and nation, before the time of these three. Some say that they were contemporary with *Prydain*, son of *Aez the Great*; but according to others, they lived in the time of *Dynwael Mael Mad*, his son, who in some of the old books is called *Dynwarth*, son of *Prydain*. For a further account of these institutional bards, and of the triads that exhibit their character, office, and privileges, and that illustrate their theology, we must refer the curious who wish for further information on this subject, to Williams's Poems, lyric and pastoral, in 2 vols. 8vo. London, 1794; and to Owen's Heroic Elegies of Llywarch-tten, in 1 vol. 8vo. London, 1792. According to the latter of these writers, the bards were divided into Bards Braint, who were the civil magistrates or judges; and Bards Druid, who were the priests of the community.

From the triads above referred to the reader may deduce a correct outline of bardism; and as to the detail of its various parts, he may be surprized to be told that they are still preserved in various memorials of the ancient Britons, and in the memory of its initiated; though it is generally supposed that this extraordinary system, known to the world under the name of Druidism, has perished above fifteen hundred years past, except the few hints given of it by Greek and Roman writers. Lost it certainly would have been but for its extraordinary means and precaution for self-preservation; especially in the middle ages, when it had to withstand the persecutions of the popish church in the fulness of its power. Here it may be worthy to remark that bardism contains a great many things to induce a conviction of its being the parent of free-masonry; and some of the principles taught in both are the same in expression; and indeed it is very remarkable, that artisan, or mason, is exactly the meaning of *ovyz*, or ovate, the name of the third class of bards; and in this character only could the bards meet under cover. Free-masons do so now; but they preserve a traditional memorial of their meeting anciently on the tops of their highest hills, and in the bottoms of the lowest vales, and when the sun was in its due meridian. Thus bardism, whose principles were to be diffused in the

face of the sun and in the eye of the light, for the sake of truth and self-preservation, had the means of becoming even more secret than masonry veiled in the darkness of night.

There were three different classes of this order in Wales: the first was called "Beirdas," and they were the composers of verses and odes in various measures; they were likewise the recorders of the arms of the Welch chieftains, and the repositories also of the genealogies of families. This class was accounted the most honourable, and was high in the public estimation. The second class, called "Mistrel," were performers upon instruments, chiefly the harp and the crwth. The third were those who sung to musical instruments in general, and were called "Datgeniad."

The talents of the Welsh bards were not solely employed in preserving the descents of families, in the praise of heroes, or in recording their illustrious actions; they sometimes in plaintive numbers mourned over the tomb of the fallen warrior.

When tyranny erected her banner in Wales, by the cruel policy of Edward in the massacre of the bards, that ancient seat of music and poetry was deserted by the muses, and consequently was deprived of those fascinating arts which softened, at the same time that they invigorated, the genius of the people. During the spirited, and for a while the prosperous insurrection of Owen Glendwrwy, the muses revisited their native seats, encouraged by the munificence of that leader, and animated by the transitory ray which had dawned upon freedom. When the Welsh had made the last effort for their expiring freedom, they sunk into a state of slavery the most deep and severe. The bards were prohibited by law from making their annual progress, and from holding public assemblies; which privileges were called by the natives "clera" and "cymhotha." During this period, and the contest between the house of York and Lancaster, the genius of poetry was nearly extinguished, or was only employed in soothing the misery of the times, by obscure predictions of more prosperous days. A brighter prospect opening on this nation in the reign of Henry VII. a series of bards arose from that time; and these bards, being supported in the families of the Welch chieftains, ascertained and preserved their genealogies; and as the causes of reciting warlike exploits had ceased, they celebrated the civil virtues of their patrons, their magnanimity, their hospitable spirit, their talents, and the graces of their persons. They likewise, amidst other duties, had the mournful office of composing an elegy on the death of the chieftain in whose family they resided, which was sung to the surviving relations in honour of the dead, reciting the noble families from which the deceased had sprung, and the great actions performed by himself or his ancestors.

Since the reign of queen Elizabeth, there has not been any regular assembly of the bards. The motives to emulation having ceased, and the spirit of ancient freedom being extinguished, the poetic fire, for which the Welsh nation had been so renowned, gradually declined. But a spark of that ancient fire still remains in the genius of the Welsh, which, in the seasons of their festivity, breaks out into a singular kind of poetry, called "*penyll*." Even at this day some vein of the ancient minstrelsy survives among the Welsh mountains. Numbers of persons assemble, and sit round the harp, singing alternately "*penillion*," or stanzas of ancient or modern compositions. Often, like the modern improvisatore of Italy, they sing extempore verses; and a person conversant in this art readily produces a "*penyll*" apposite to the last that was sung. Many have their memories stored with several hundreds, perhaps thousands of "*penillion*," some of which they have always ready for answers to every subject that can be proposed, or if their

recollection should fail them, their invention supplies them with something pertinent and proper for the occasion.

Bards have been found in many countries; and continued in Ireland and Scotland, as well as in Wales, to our own days. The genealogical fonnets of the Irish bards are still the chief foundations of the ancient history of Ireland.

Spenser, the poet, in his view of the state of Ireland in the reign of queen Elizabeth, observes that he caused several compositions of the bards to be translated; "and surely," he adds, "they favoured of sweet wit and good invention, but skilled not of the goodly ornament of poetry; yet were they sprinkled with some pretty flowers of their natural device, which gave good grace and comeliness unto them; the which it is great pity to see abused, to the gracing of wickedness and vice, which with good usage would serve to adorn and beautify virtue."

The songs of the Irish bards, says Warton in his "History of English Poetry" (dist. i. vol. i.), are by some conceived to be strongly marked with the traces of Scaldic imagination; and these traces are believed still to survive among a species of poetical historians, whom they call "Tale-Tellers," supposed to be the descendants of the original Irish bards. The Irish historians inform us that St. Patrick, when he converted Ireland to the Christian faith, destroyed 300 volumes of the songs of the Irish bards. Such was their dignity in this country, that they were permitted to wear a robe of the same colour with that of the royal family. They were constantly summoned to a triennial festival; and the most approved songs delivered at this assembly were ordered to be preserved in the custody of the king's historian or antiquary. Many of these compositions are referred to by Keating, as the foundation of his history of Ireland. Ample estates were appropriated to them that they might live in a condition of independence and ease. The profession was hereditary; but when a bard died, his estate devolved not to his eldest son, but to such of his family as discovered the most distinguished talents for poetry and music. Every principal bard, as we have already observed, retained thirty of inferior note as his attendants; and a bard of the secondary class was followed by a retinue of fifteen. They seem to have been at their height in the year 558. None of their poems have been translated.

In the highlands of Scotland there are considerable remains of many of the compositions of their old bards still preserved. But the most genuine, entire, and valuable remains of the works of the ancient bards, and perhaps the noblest specimen of uncultivated genius, are the poems of Ossian, the son of Fingal a king of the Highlands of Scotland, who flourished in the second or third century, lately collected by Mr. Macpherson, and by him translated from the Erse or Gaelic language into English. Dr. Johnson, indeed, has suggested his doubts concerning the existence of any such ancient MSS. as those from which the poems of Ossian have been translated. But this is not a place for discussing this subject of controversy. Admitting, however, their genuineness upon the whole, whatever additions may have been made to them, they afford an admirable specimen of what might be the conceptions of ancient bards. These poems, says Warton (*ubi supra*), notwithstanding the difference between the Gothic and the Celtic rituals, contain many visible vestiges of Scandinavian superstition. The allusions in the songs of Ossian to spirits who preside over the different parts, and direct the various operations of nature, who send storms over the deep, and rejoice in the shrieks of the shipwrecked mariner, who call down lightning to blast the forest or cleave the rock, and diffuse irresistible pestilence among the people, beautifully conducted and heightened under the skilful hand of a master bard, entirely correspond

with the Runic system, and breathe the spirit of its poetry. Had Ossian found it convenient to have introduced religion into his compositions, not only a new source had been opened to the sublime, in describing the rites of sacrifice, the horrors of incantation, the solemn invocations of infernal beings, and the like dreadful superstitions, but probably many stronger and more characteristic evidences would have appeared of his knowledge of the imagery of the Scandinavian poets.

The remains of Taliesin, and other Welsh poets, assist us in forming a competent judgment upon this subject. See Evans's Dissertation de Bardis. Jones's Musical and Poetical Relics of the Welsh Bards.

It is not improbable, says Warton (*ubi supra*), that the Welsh bards might have been acquainted with the Scandinavian Scalds, at least before their communication with ARMORICA. The bards flourished most in those parts of Britain which most strongly retained their native Celtic character. The prosody of the Welsh bards depended much on alliteration; hence they seem to have paid an attention to the Scaldic versification. The Islandic poets are said to have carried alliteration to the highest pitch of exactness in their earliest periods; whereas the Welsh bards of the sixth century used it but sparingly, and in an imperfect degree: from this circumstance we may deduce a proof of imitation, or at least of emulation. There are, moreover, strong traces of conformity between the manners of the two nations. Besides, the Scandinavian Scalds were well known in Ireland; and there is sufficient evidence to prove that the Welsh bards were early connected with the Irish. Even so late as the eleventh century, the practice continued among the Welsh bards of receiving instructions in the bardic profession from Ireland. The Welsh bards were reformed and regulated by Gryffyth ap Conan, king of Wales, in the year 1078. At the same time he brought over with him from Ireland many Irish bards for the information and improvement of the Welsh. In Ireland, to kill a bard was highly criminal; and to seize his estate, even for the public service and in time of national distress, was deemed an act of sacrilege. Thus, in the old Welsh laws, whoever even slightly injured a bard, was to be fined 6 cows and 120 pence. The murderer of a bard was to be fined 126 cows. Moreover, an intercourse was necessarily produced between the Welsh and Scandinavians from the piratical irruptions of the latter. It may be added, that the Welsh, although living in a separate and detached situation, and so strongly prejudiced in favour of their own usages, yet from neighbourhood and unavoidable communications of various kinds, might have imbibed the ideas of the Scandinavian bards from the Saxons and Danes, after those nations had occupied and overspread all the other parts of our island. (See SCALDS.) The effect of an intercourse with Armorica is perceived in the composition of those Welsh bards who flourished after the native vein of British fabling had been tinged by the "fairy tales" which had been propagated by the Arabians in ARMORICA, and which the Welsh had received from their connection with that province of Gaul. It is easy to collect from the Welsh odes, written after the tenth century, many signatures of this exotic imagery. See SCANDINAVIA, and ARMORICA.

BARDSEY-ISLE, in *Geography*, an island of Wales, called in Welsh *Yr Ynis Enlli*, or the island in the current, from the fierce current which runs between it and the main land; and Bardsey, probably from the bards who retired here. It forms the north point of Cardigan bay, and is situated opposite to it, within the county of Caernarvon. At Aberdaron bay there is good anchorage; but the entrance for large ships is very difficult. It was to this place that Dubritius, arch-

archbishop of Caerleon, retired after he had resigned his see to St. David, and here he is said to have died in 612. *Bardsey Abbey*, of which the remains are considerable, was founded in the year 516. A singular oratory belonging to it, consists of a long arched edifice, with an insulated stone altar near the east end. The island forms a remarkably fertile and well-cultivated plain of about two miles in compass. It contains a few inhabitants, and is rented from lord Newborough. It was granted by Edward VI. to his uncle sir Thomas Seymour, and after his death to the earl of Warwick. The late sir John Wynn purchased it from the late Rev. Dr. Willon of Newark. It is 10 leagues N. E. by N. of Caernarvon bar, and 12 leagues N. by W. of Holyhead in the isle of Anglesea. N. lat. $52^{\circ} 58'$. W. long. $5^{\circ} 5'$.

BARDSTOWN, a town of Kentucky, in the United States of North America, and chief place of the county of Nelson, on the Beech Fork river; about 25 miles from the Ohio. N. lat. $37^{\circ} 48'$. W. long. $86^{\circ} 13' 35''$.

BARDT, or **BARTH**, a post-town of Germany, in the duchy of Pomerania, situated in a small bay on the Baltic, 6 leagues west from Stralsund. It belongs to Sweden. N. lat. $54^{\circ} 20'$. E. long. $13^{\circ} 20'$.

BARDUBITZ, or **PARDUBITZ**, a town of Bohemia, in the circle of Chrudim, celebrated for its manufactures; seated on the Elbe; 6 miles north of Chrudim.

BARE, in a general sense, signifies not covered. Hence we say, bare-headed, bare-footed, &c.

The Roman women, in times of public distress and mourning, went bare-headed, with their hair loose.

Among Greeks, Romans, and Barbarians, we find a feast called *nudipedalia*, at which persons were to attend bare-footed.

The Abyssinians never enter their churches but bare-footed; not on account of Moses, who was commanded to put off his shoes on mount Sinai, but in reverence of the place; as is also done by them in entering the palaces of kings and great men.

Sagittarius has a dissertation on those who went bare-footed among the ancients, "De Nudipedalibus Veterum;" wherein he treats of such as went bare-footed in journies or otherwise, either out of choice or necessity; also of bare-footed religious mourners and penitents, who went bare-footed; and, lastly, of the *lexiri*.

BARE, in respect of *Manufecture*. A cloth is said to be bare or naked when the nap is too short, as having been shorn too near, or not being sufficiently covered with wool by the teazel.

BARE is also used for a sort of bowling ground, not covered with green sward.

BARE-FOOT CARMELITES, and *Augustines*, are religious of the order of St. Carmel, and St. Augustin, who go without shoes like the Capuchins.

There were also bare-foot fathers of mercy. Formerly there were bare-foot Dominicans, and bare-foot nuns of the order of St. Augustin.

BARE-FOOTED TRINITARIANS. See TRINITARIAN.

BARE-PELES, under, in *Sea Language*, expresses the state of a ship, when she has no sail set.

BARE-PUMP. See PUMP.

BARE, in *Geography*, an island in the Southern Pacific ocean, near the east coast of New Ireland. It is high land, not fertile, but inhabited; situate in S. lat. $39^{\circ} 57'$. and S. S. W. from cape Kidnappers.

BARE HAVEN, lies on the coast of Nova Scotia, in North America, about 3 leagues S. W. from cape Canso. It is sheltered by an island off the point called White point.

BAREA, in *Ancient Geography*, a town of Spain,

upon the Iberian sea, in the country of the Bastuli. Ptolemy.

BAREILLE, in *Geography*, a province of Hindostan, in the country of Lahore, between the rivers Rauvee, Beyah, and Setledge.

BAREGE WATERS, in the *Materia Medica*, are celebrated thermal waters, situated in and near the village of Barege, on the French side of the Pyreæes, at the foot of these lofty mountains. There are four principal hot springs in this place, which differ, however, very considerably in temperature, the highest being about 120° Fabr. and the lowest about 73° . This variety of heat gives every convenience for bathing, drinking, and topical application. Chemical analysis shews in this water a quantity of sulphur, in the form of sulphurated hydrogen, united to a small portion of soda, a little common salt, and a kind of slimy bituminous matter. The sulphur and the soda, together with the heat, may be considered as the active ingredients, but the quantity of them is very small; as the water scarcely exceeds distilled water in specific gravity.

The waters of Barege are remarkable for a smooth soapy feel, and they give suppleness and smoothness even to dead skin that is immersed in them. They are used chiefly as a discutient and detergent bath, in resolving indolent tumours and rigidity of the joints left by gouty or rheumatic affections. They are also of great advantage in cutaneous diseases. Internally taken, the water gives relief in disorders of the stomach, heartburn, indigestion, cholic, and also in several calculous affections of the urinary organs. Saunders on Mineral Waters.

BAREITH, **BAREUTH**, or **BAYREUTH**, in *Geography*, a town of Germany, in Franconia, in the margravate of Culmbach. It is the capital of the principality, and often called the principality of Bareuth. Its palace, which was burnt down in the year 1753, was again rebuilt in a beautiful style. It has one Calvinist, and two Lutheran churches, a Roman catholic chapel, a public school, a foundling hospital, and an academy, founded in 1722 by the margrave Fredric, besides the college. In 1430, this town was burnt down by the Hussites. It belonged to a prince of the house of Brandenburg, the last of whom dying in 1782, it descended to the king of Prussia. Near the Fichtelburg, Bareuth produces a variety of beautiful marbles, and some curious minerals. The principality of Bareuth is also known by the name of Culmbach; and, with Onolzbach, forms the chief power in Franconia, now annexed to the sovereignty of Prussia. N. lat. $50^{\circ} 0'$. E. long. $11^{\circ} 50'$.

BARELLY, a town of Hindostan, in the province of Oude; 41 miles S. S. E. of Lucknow.

BAREN, a river of Germany, which runs into the Roer, near Schwiert, in the county of Mack, and circle of Westphalia.

BAREN, a town of Sallerland, in the Valais, 25 miles east of Sion.

BARENA, in *Ancient Geography*, a town of Asia, in Media, near Ecbatana. Steph. Byz.

BARENTELS, in *Geography*, a town of Germany, in the circle of Upper Saxony, and county of Erzgebürg, 2 miles west of Altenberg.

BARENSTEIN, or **BERNSTEIN**, a town of Germany, in the circle of Upper Saxony, and margravate of Meissen, 17 miles south of Dresden.

BARENT, **DITTRICK**, in *Biography*, a painter of history and portrait, was born at Amsterdam in 1534; and having received early instruction from his father, travelled to Venice, where he was admitted into the school of Tician, and became the favourite disciple of that inimitable master.

With

With Titian he continued several years, and painted a portrait of him, which gained him great reputation; and he was singularly successful in imitating the touch, the manner, and the style of colouring, peculiar to that excellent genius. Upon his return to his own country, he was very much employed in works that added to his honour; but the composition, which contributed more than any other to establish his fame, was the picture which represented the fall of Lucifer, containing a number of figures, naked, well contrasted, and excellently coloured. He died in 1582. Pilkington.

BARENTIN, in *Geography*, a town of France in the department of the Lower Seine, 3 leagues N.W. of Rouen.

BARENTON, a town of France, in the department of the Channel, and chief place of a canton in the district of Mortain, seated at the source of the Arde, containing about 2000 inhabitants, and distant 7 leagues E. S. E. from Avranches, and $1\frac{1}{2}$ S. E. of Mortain.

BARESUND, a sea-port town of Sweden, in the province of East Gothland, between Nordkiöping and Söderkiöping.

BARETTI, JOSEPH, in *Biography*, was the son of an architect of reputation, and born at Turin about the year 1716. He received a good education, but squandered his patrimony in gaming. Being of a rambling and desultory disposition, he was frequently reduced, notwithstanding his talents and literary character, to circumstances of distress. In 1748, he was employed at Venice in teaching the Italian language to some English gentlemen; and in 1750, at the instigation of lord Charlemont, he visited England, which was the place of his future residence. Possessing a wonderful facility in acquiring the knowledge of languages, as well as a critical acquaintance with his own, his talents were well adapted to the profession of a teacher of languages, in which he engaged. In 1753 he wrote a treatise in English, which was "A Defence of the Poetry of his native country against the censures of Voltaire." About this time an acquaintance commenced between Baretti and Dr. Johnson, which was kind and cordial on the part of the latter, and respectful in the highest degree on the part of the former. As he had acquired reputation by some works which he had published on the Italian language and literature, he availed himself of his friend's English dictionary to compile a dictionary of the Italian and English languages, which first appeared in 1760, and which maintains its superiority over all other works of the same kind. In this year he visited his native country, with some prospects of preferment, in which he was disappointed; but on his arrival, he published at Venice a periodical work, intitled "Frustra Literaria," under the character of an old complaining soldier who was returned to his country after long absence. His criticisms, however, in this work, which met with great success, were so severe, that he was obliged to leave the country; and after an absence of six years, he returned through Spain and Portugal to England. In 1768 he published "An Account of the Manners and Customs of Italy," intitled chiefly as a reply to the severe strictures of Mr. S. Sharp, the surgeon, in his "Letters from Italy." By Dr. Johnson he was introduced into the family of Thrale, both as a teacher and a literary guest. In 1769, he visited Spain, probably intending to complete his account of a tour in that country. Soon after his return, an accident occurred, which was followed by very distressing consequences. Having engaged in an angry altercation with a woman of the town in the Hay-market, he was accosted by three men, who insulted and jostled him. Alarmed for his life, Baretti took out of his pocket a French desert knife, and

attacked one of the assailants; and unfortunately pursuing the contest and repeating the blows, he inflicted wounds which proved fatal. He was arrested and tried for murder at the Old Bailey. In this trial the public were much interested; and a number of men of the first literary eminence appeared to bear testimony to Baretti's character; among whom were Johnson, Burke, Garrick, Goldsmith, Reynolds, and Banelier. The event was the acquittal of Baretti; but the charge very materially affected his reputation. In 1770 he published his "Journey from London to Genoa, through England, Portugal, Spain, and France," 4 vols 8vo. which was deservedly well received; and he continued publishing introductory works for the use of students in the Italian and some other modern languages. Although he had been domicicated in the family of Mr. Thrale, he left it in 1776, in disgust, and by this sudden start of whim or ill-humour, involved the latter part of his life in many inconveniences and difficulties. His attempt, in 1779, for introducing to the public a classical entertainment, which was the "Carmen Seculare" of Horace set to music, failed of success. Reduced to a state of precarious subsistence, he obtained under lord North's administration a pension from government of 80*l.* a year, but during the urgency of public wants this fell into arrears, and Baretti could scarcely preserve himself from absolute indigence. His last performance was published in 1786, and was intitled "Telendien: Speeches to John Burke about his edition of Don Quixote; together with some account of Spanish literature." Oppressed by anxiety and uneasiness of mind, and with a constitution impaired by fits of the gout, he died on May 5th, 1789. Baretti, although he had a rough and somewhat cynical appearance, was popular for society, and his conversation was instructive, particularly to young persons, with whom he had much intercourse. Having lived much in the world, and having had no opportunity in early life of acquiring fixed principles, he indulged a considerable laxness and freedom of opinion. However his integrity was unimpeached, his morals were pure, and his manners were correct. His charity had no bounds, and by the imprudence with which he exercised it, he was himself involved in difficulties. His literary talents, though not of the highest order, were useful and agreeable. "I know no man," said Dr. Johnson to Boswell, "who carries his head higher in conversation than Baretti; there are strong powers in his mind; he has not, indeed, many hooks, but with what hooks he has he grapples very forcibly." Boswell's Life of Johnson. Europ. Mag. for 1789. Geo. Biog.

BAREUX, in *Geography*, a town of France, in the department of the Lower Pyrenées, and chief place of a canton in the district of Mauleon, 5 miles south-east of Mauleon.

BAR-FEE, in *Law*, a fee of 20 pence, which every person acquitted of felony pays the gaoler.

BARFLEUR, in *Geography*, a sea-port town of France, in the department of the Channel. It had formerly a good harbour and a considerable trade; but in consequence of neglect, the harbour is choaked with sand, and the trade decayed. Cape Barfleur is 6 leagues east from Cherbourg, in N. lat. 49° 40'. W. long. 1° 17'.

BARGA, a town of Italy, in the duchy of Tuscany, on the river Sechio, 2 leagues from Lucca.

BARGAIN, in a *General Sense*, a contract either for the sale, purchase, or exchange of a thing. The word is formed from the French *baraigner*, to barter or haggle. He that sells is the *baraignor*, and he that buys the *baraignee*.

BARGAIN and Sale, in *Law*, is properly a contract made

of manors, lands, and other things, transferring the property thereof from the *bargainor* to the *bargainee*, for a consideration in money: or, it is an instrument by which the property of lands and tenements is for valuable consideration granted and transferred from one person to another. It is called a real contract upon a valuable consideration, for passing of lands, tenements, and hereditaments, by deed indented and enrolled. 2 Inst. 672.

It is a good contract for land, and the fee passes, though it be not said in the deed, to have and to hold to him and his heirs, and though there be no livery and seisin given by the vendor, so it be by deed indented, sealed, and enrolled, either in the county where the land lies, or in one of the king's courts of record at Westminister, within six months after the date of the deed.

This manner of conveying lands was created and established by the 27 Hen. VIII. c. 10. which executes all uses raised; and as this introduced a more secret way of conveying than was known to the policy of the common law, therefore the enrolment of the deed of *bargain and sale* was made necessary by the 16th chapter of that statute. The objects of this provision evidently were, first, to enforce the contracting parties to ascertain the terms of the conveyance by reducing it into writing; secondly, to make the proof of it easy, by requiring their seals to it, and consequently the presence of a witness: and lastly, to prevent the frauds of secret conveyances, by substituting the more effectual notoriety of enrolment, for the more ancient one of livery. But the latter part of this provision, which, if it had not been evaded, would have introduced almost an universal register of conveyances of the freehold, in case of corporeal hereditaments, was soon defeated by the invention of the conveyance by lease and release, which sprung from the omission to extend the statute to bargains and sales for terms of years: (See 8 Co. 93. 2 Ro. Abr. 204. 2 Inst. 671.) and the other parts of the statute were necessarily ineffectual in our courts of equity, because these were still left at liberty to compel the execution of trusts of the freehold, though created without deed or writing. The inconveniences arising from this insufficiency of the statute of enrolments are now in some measure prevented by stat. 29 Car. II. c. 3. which provides against conveying any lands or hereditaments for more than three years, or declaring trusts of them, otherwise than by writing. 1 Inst. 48 a. n. 3. See Blackst. Com. vol. ii. p. 338. Jacob's Law Dict. by Tomlyns, Art. *Bargain and Sale*.

BARGAINS, in *Commerce*, are of divers kinds: *verbal*, those made only by word of mouth, and giving earnest; *written*, those where the terms are entered in form on paper, &c.

At Amsterdam they distinguish three kinds of *bargains*.

BARGAINS, *Conditional*, for goods which the seller has not yet in his possession; but which he knows have been bought for him by his correspondents abroad, and which he obliges himself to deliver to the buyer, on their arrival, at the price and the conditions agreed on.

BARGAINS, *Finis*, those wherein the seller obliges himself to deliver to the buyer a certain quantity of goods, at the price and in the time agreed on.

BARGAINS, *Optional*, those wherein a dealer obliges himself, in consideration of a *premium* received in hand, either to deliver or take a certain quantity of goods at a fixed price, and within a time limited; but with a liberty, nevertheless, of not delivering or not receiving them, if they think proper, upon forfeiture of their *premium*.

BARGAINS, *Forhand*, are those, wherein goods are bought

or sold, in order to be delivered at a certain time afterwards, some part of the price being advanced.

BARGASA, in *Ancient Geography*, a town of Asia, in Caria, seated at the bottom of the gulf called Ceramicus.

BARGAZAR POINT, in *Geography*, a cape on the coast of Iceland. N. lat. 66° 18'. W. long. 16° 38'.

BARGE, in *Navigation*, a kind of flate, or pleasure-boat, or large luggage-boat, used chiefly in the navigation of rivers which lead to great cities.

Barges are of various kinds, and acquire various names, according to the variety of their uses and structure: a,

- A company's barge,*
- A row barge,*
- A royal barge,*
- A sand barge,*
- A Severn iron,*
- A Ware barge,*
- A light horseman,*
- A West-country barge.*

A barge differs from a bark, as being smaller, and used only on rivers; whereas the latter goes out to sea.

There are also barges, belonging to men of war, serving to carry generals, admirals, and chief commanders.

Sailing barges are vessels with one mast, and sometimes a bowsprit. Those that have boom-fails, are rigged like sloops; but, having few hands on board, the boom and gaff are more easily hoisted or topped, the power being increased by the addition of blocks. Sailing lighters or barges, with a sprit-main-sail, rig with a sprit-yard at the head of the sail, hanging diagonally to the mast. Some large barges have vangs like a ship's mizen, and a down-hauler at the peak-end of the sprit-yard. Large barges have a fore-sail, jib, cross-jack-yard, and top-sail, similar to sloops.

BARGE, or *Barges*, in *Geography*, a town of Piedmont, in the district of the 4 Vallies, 7½ miles south of Pinero-la.

BARGE-Brune, in *Ornithology*, Buffon's name of the dusky snipe; *scelopax fusca*, Gmelin.

BARGE-Blanche, is likewise a name assigned by Buffon to the white avofet, *recurvirostra alba*, Gmelin.

BARGE' le Chatel, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Pont-de-Vaux, 4½ leagues W.N.W. of Bourg-en-Bresse. N. lat. 46° 19'. E. long. 4° 49'.

BARGE-Couples, in *Architecture*, a beam mortised into another, to strengthen the building.

BARGE-Course is used by workmen, to signify a part of the tiling, which projects over the gable of a building, and is made up with mortar.

BARGEMON, in *Geography*, a town of France, in the department of the Var, and chief place of a canton in the district of Draguignan, 2 leagues N.N.E. of Draguignan.

BARGH, is used in some places of England for a steep horse-way up a hill.

It seems to come from the German *bargh*, a hill.

BARGH-Master, BARNER, or BAR-Master, in the *Royal Mines*, the steward or judge of the barghmote.

The word is formed of the German *berg-maister*, q. d. *maister of the mines*.

The bar-maister is to keep two great courts of barmote yearly, and every week a small one, as occasion requires.

BARGHMOTE, or BARMOTE, a court which takes cognizance of causes and disputes between miners.

Some suppose it thus called from a *bar*, at which the suitors appear; others, with more probability, deduce the word from the German *Laz*, a mine.

By the custom of the mines, no person is to sue any miner for ore-debt, or for ore, or for any ground in a mine, but only in the court of barmote, on penalty of forfeiting the debt, and paying the charge at law.

BARGIACIS, in *Ancient Geography*, a town of Hispania Tarraconensis, situated in the inner part of the country, and in the territory of the Vaccæans. Ptolemy.

BARGIE, in *Geography*, the name of a barony in the northern part of the county of Wexford, province of Leinster, Ireland, which, with the adjoining one of Forth, was peopled by the followers of earl Strongbow. The language used there is said to be a broken Saxon, more like Flemish than English, and not one in a hundred knows any thing of Irish. "They are evidently," says Mr. Young, "a distinct people, and I could not but remark that their features and cast of countenance varied very much from the common native Irish. The girls and women are handsome, having much better features and complexions. Their industry is superior to that of their neighbours; and their better living and habitations are also distinctions not to be forgotten. The poor have all barley bread and pork, herrings and potatoes. On the coast there is a considerable fishery of herrings." Both men and women wear straw hats, which give them a comic appearance. The inhabitants are reckoned more industrious and cleanly, and better farmers than in any other part of Ireland; but Mr. Young found their system very defective. The farms were in general from 20 to 80 acres at an average rent of a guinea per acre. The soil is light, and being extremely well tilled, produces large quantities of barley. Young's Tour, and Latoenay's Rambles through Ireland.

BARGOSA, in *Ancient Geography*, a town of India, which was the country of the philosopher Zarmanochegas, who committed himself to the flames in the presence of Augustus, according to Strabo.

BARGOTA, in *Geography*, a town of Spain, in Navarre, 6 leagues from Estella.

BARGULIA, or **BARGULUS**, in *Ancient Geography*, a place of Illyria, in the neighbourhood of the people denominated Parthini, which Philip ceded to the Romans by a treaty, 204 years before the vulgar æra.

BARGUS, a river of Illyria, both sides of which were inhabited by the Scordisci; it discharged itself into the Illyr, according to Strabo. Pliny says, that a river of this name flowed into the Hebrus.

BARGUSII, an ancient people of Spain, to whom envoys were sent from Rome to solicit the Spaniards to take part with the Romans rather than with the Carthaginians. They inhabited the interior of Spain, on the other side of the Ebrus; and were subdued by Hannibal. Livy, l. xxi. c. 19, 23.

BARGUSIN, in *Geography*, a town of Siberia, in the province of Nerthinsk, in the government of Irkutsk, formerly an ostrog, now a circle-town, on the right bank of the river Bargusian, 20 versts above where it falls into the Bargusian bay of the Baikal, 53° lat. 127° long. 524 versts north-east from Irkutsk. It is chiefly remarkable on account of the baths in its district. They were discovered in a waste region at the distance of eighty versts from any habitation. M. Grand, sergeant to a regiment quartered in those parts, having successfully prescribed the use of these baths to several patients, M. Von Klittha, the governor of Irkutsk, in 1779, caused some buildings to be erected there. They have proved of great benefit to persons afflicted with rheumatism, scurvy, phthisis, and other complaints of a like nature. The water is drank either pure, or, on account of its nauseous taste resembling that of rotten eggs, mixed with milk. It promotes perspiration, does not quench thirst, and may be drank in large portions. When boiled, it is of a very agreeable taste, and is particularly good with tea.

BARGYLA, **BARGYLIA**, or **BARGULEA**, in *Ancient*

Geography, a town of Asia Minor, in Caria, near Jafos and Mindos. It is mentioned by Pliny, Strabo, and Ptolemy. It was situated near the Meander, south of Miletus. M. d'Anville places it north-east of Halicarnassus, on the gulf called Iassius.

BARGYLUS, a mountain of Phœnicia, on the confines of Syria, on the way towards Antiochene. It was situated north of mount Libanus.

BARH-NAGASH, in *Geography*. See **BAHARNA-GASH**.

BARI, a sea-port town of Italy, in the kingdom of Naples, on the coast of the Adriatic; once the capital of a province of the same name, and see of an archbishop. It is well-built, populous, and has a good trade. The harbour was almost destroyed by the Venetians. 120 miles E.N.E. of Naples. N. lat. 41° 31'. E. long. 17° 40'. It contains, says Swinburne, about 6000 persons.

BARI, or *Terra di Bari*, a province of Naples, deriving its name from its capital. It is bounded on the north and north-east by the sea, on the east and south-east by the province of Otranto, on the south by the Basilicata, and on the west and north-west by the Capitanata. It is about 62 miles long, and its mean breadth is rather more than 20 miles. It produces corn, wine, oil, cotton, flax, and fruits; and the coast is guarded against the corsairs by sixteen towers. Its sea-ports are Barletta, Trani, Bari, and Molfetra; its mountains are Sanazzo, Femina Morta, Lupulo, Franco, and St. Agostino; and its rivers are Ofanto and Cane. The extent, according to Swinburne, is 869,097 moggie, 5 moggie being equal to 4 English acres: and he states the number of its inhabitants to be 281,048. The city of Bari is the ancient Barium; and coins struck by its principal magistrates still exist. The Lombards, Greeks, and Saracens disputed the possession of this city in the ninth century. In the tenth, it rose to distinction on becoming the residence of the Greek catapan or viceroy, and of a metropolitan bishop. The book of constitutions, compiled for the juridical government of the province, and still in use, is a respectable voucher for the importance and policy of Bari during the middle ages. About the year 1000, Bari became the scene of conspiracies and revolutions. Melo confederated against the Grecian emperor in this place; but it retained its subjection to the eastern emperor, and was one of the last and firmest supports of his dominion. In 1067, Robert Guiscard invetted it by sea and land, and enclosed it by a semicircle of ships joined together by chains and booms, in order to prevent its obtaining succours. This blockade lasted four years. Earl Roger afterwards joined his brother with a strong fleet, defeated the Imperial squadron sent for the relief of the city, and made its admiral prisoner; upon which Bari opened its gates to the conquerors. A citadel was erected by king Roger for securing the allegiance of this town, but it was hardly finished when Lotharius razed it to the ground. At this time, Bari was a populous and strong place. It was afterwards treated with great severity by William the Bad, who levelled the dwellings of the inhabitants who joined in the grand rebellion against him to the ground. The city, however, must have risen speedily out of its ruins, as the emperor Frederick established an annual fair here in 1233; but in 1248, he ordered the town to be destroyed, by way of punishing the inhabitants for treasonable practices. Bari frequently changed its proprietors, till it was settled by Alphonfus the second upon the family of Sforza, in consideration of the marriage of his daughter Isabella with the duke of Milan. According to treaty, these estates became the property of Bona, queen of Poland, at whose death this duchy returned

to the crown, to which it has ever since remained annexed. Swinb. Travels, vol. ii. p. 1, &c.

BARIANA, in *Ancient Geography*, a town of Asia, in Mesopotamia. Ptolemy.

BARIARED, in *Geography*, a town of Persia, in the province of Kerman, 19 leagues S. W. of Sirgian.

BARIEL, or **BARNACLE POINT**, is the south-eastern limit of Winthrop's bay on the north-east coast of Antigua island, and on the west side of the channel into Parham harbour.

BARILLA, or **BARILHA**, is the term by which the impure mineral alkali from the coasts of Spain and some other parts of the Levant is known in commerce. That from Alicante and the coasts of the province of Murcia is the most esteemed. It is brought over in the form of hard brown speckled porous masses almost without smell, and tasting strongly alkaline. It is procured by burning to ashes several plants growing on the sea-shore of the species of *Salsola* and *Kali*. For the particulars of this manufacture, see the article **SODA**. The term *British borilla* is also applied sometimes to **KELP**, a much more impure soda, and sometimes, though improperly, to *pearl-shells*, or the ashes of plants containing *potash*, the vegetable alkali.

BARILLARIUS, an ancient officer in monasteries and great households, who had the care of the casks and vessels of wine, &c. in the cellars.

BARILLOVITZ, in *Geography*, a town of Croatia, on the river Korana, 10 miles south of Carlstadt.

BARIN, a town of Asiatic Turkey, in the province of Natolia, 12 miles south of Anafiah.

BARING OF TREES, in *Agriculture*. See **ABLAQUEATION**.

BARJOLS, in *Geography*, a town of France, and principal place of a district in the department of the Var. The town is populous, and situated in a pleasant country; 9 leagues north of Toulon. N. lat. 43° 35'. E. long. 5° 23'.

BARIQUESEMETO, a river of North America, in the country of Terra Firma, which runs into the Oroonoko.

BARISSOGLEBSK, or **BORISSOGLEBSK**, a town newly erected by Catharine II. in the province of Yaroslaf, is situate on the Volga, 57° 39' lat. 57° 9' longit. has 4 brick, and 417 wooden houses, 2076 inhabitants, and a brick church. The trade of this town consists in the produce of the fishery and several manufactories of hardware, chiefly pots and kettles. The home and foreign trade together amount nearly to 60,000 rubles. There is also a small town of the same name, situate 59° 50' lat. and 60° longit. on the Khoper, in the government of Tambow, consisting of 400 timber-houses, and 894 male inhabitants, several of whom are shop-keepers. It has two timber churches. The merchants a few years since inscribed themselves in the registers as possessing a capital of only 13,126 rubles. Here is a considerable distillery.

BARITONO, in *Music*, a voice of low pitch, between a tenor and bass. The term is formed of two Greek words *βαρυς*, grave, and *φωνή*, tone. But those who are not partial to bass voices, rather choose to derive the word from the Italian verb *barire*, to bray.

BARK, in *Vegetable Anatomy*, is a term by which is commonly understood the exterior part of vegetable bodies; which is separable from the other parts of the plant without much difficulty, during the season of vegetation; but at other periods requires maceration in water, or boiling, and when detached by any of these means, the finer connexions which unite it to the wood are necessarily destroyed.

When bark is thus separated, and subjected to microscopic examination, it exhibits parts differing much in structure and use. These have been divided by anatomists into the

epidermis; or *cuticle*, the *cellular envelope* or *parenchyma*, and the *cortical layers* and *liver*.

The *Epidermis* is situated most externally, and gives a covering to every part of the vegetable body, except the anthers and pistils of flowers. Its texture is varied not only according to the species of plant to which it belongs, but also by the different parts of the same plant; thus, it is strong, dry, and unyielding, upon the roots and trunks of trees; commonly smooth, glossy, and flexible upon leaves and flowers; and sometimes it is villous, or covered with fine projecting processes like hairs.

The most usual colour exhibited by the epidermis is that of green upon the younger branches, and an ash colour upon those parts of the plants which are most aged; it is however white and shining in the birch, red and silvery in the cherry-tree, and brown upon the horse-chestnut and apple-tree &c. The epidermis is notwithstanding, in all cases, a transparent membrane, and derives its colour from the substance which is placed immediately behind it, in the same manner as the colour of the skin of animals is produced by the existence of the mucous membrane.

In order to examine the epidermis of vegetables with success, it is necessary to detach it from the cellular tissue, upon which it is immediately applied. This is not difficult to perform, when the plant is full of sap, at which time the epidermis may be removed by a fine knife or lancet; but at other periods it must be submitted to a previous maceration in water before it will separate. When a portion of the vegetable cuticle is thus obtained, it should be inspected under water or spirits, and if viewed with a lens of moderate power, it exhibits the appearance of a plexus or network, of which the meshes are not vacant, but filled by a fine pellucid membrane, as may be seen in *Fig. 1.* of *Plate I.* in *Vegetable Anatomy*; and the fibres composing the reticulation appear more condensed in some places than others, as represented by the letters *a a*. Hill describes the cuticle of plants as a triple membrane, or three plexuses laid the one upon the other. He observed, by employing high magnifying powers, that these plexuses were of regular forms; that what appeared as fibres in the perpendicular direction were longitudinal vessels, and the spaces left between these vessels were oblong cells, close at their bottom, but open at the top; and that the junction of the cells occasioned the appearance of transverse lines; and thus the reticulation was rendered complete. He even professed to have injected those vessels, by procuring an absorption of a solution of the cerussa acetata, or sugar of lead, and afterwards making it visible by adding a mixture of lime and orpiment; and in other instances he filled the longitudinal vessels by the absorption of the tincture of cochineal. The description, which has been given of the epidermis by Hill, does not appear, however, to deserve much attention, as it differs so much from that of other writers. It is indeed true, that Du Hamel and others have observed a second epidermis under the first, which appeared more green, fresh, and succulent; and that on those trees which frequently cast the cuticle, as the birch, cherry-tree, &c. there is a succession of layers; but this does not prove that the epidermis is not a single membrane when first formed, and that where there are more layers than one, each is a perfect cuticle, proceeding in its turn to be exfoliated or cast off. This mode of reparation resembles what takes place in animals, especially in some reptiles, which have the new cuticle perfectly formed, before the old one is parted with. Upon the trunks of most trees which are dicotyledons, the successive layers of epidermis continue to adhere together; each of these cracks and gives way as the tree increases in thickness, and hence the deep clefts which always appear in the bark of trees of any age. The several laminae, which

are in this manner left surrounded by the cracks, are larger or have more extent, the nearer they approach to the wood, in consequence of the most external epidermis having first yielded to the growth of the tree.

No subject has occasioned greater controversy amongst vegetable anatomists, than the mode in which the cuticle of plants is formed. It was the opinion of Malpighi and Grew, that the epidermis was produced by the last vehicles of the cellular envelope, in consequence of their exposure to the air; but if the cuticle was formed by the densification of the cellular tissue, it would not admit of that extension which takes place in all circumstances to a certain degree, and which is so remarkable in the cuticle covering leaves, flowers, and fruits, and all parts of which the growth is rapid.

Several other circumstances might be mentioned to shew that the epidermis can be produced by the drying of the cellular substance; thus when it is wounded or destroyed, and the part perfectly secluded from the action of the air, a new epidermis is soon produced without any exfoliation. The cuticle is in some instances formed, and in others continues to grow, under circumstances entirely beyond the agency of heat and evaporation, as may be observed in the fetal plant, and its appendages, and the internal surfaces of buds, &c.; but although the epidermis does not appear to be the cellular tissue simply dried by exposure, it is sufficiently plain that it is the continuation of the same membrane which forms the cellular envelope.

According to the latest observations made on this subject by Mirbel, who is one of the most ingenious vegetable anatomists of the present time, the lines which give the reticulated appearance to the epidermis, correspond in figure with the cells of the parenchyma, and are really the termination of the septa of these cells in the cuticle. (See *fig. 2. Plate I. Vegetable Anatomy.*) The tubular tissue, which in some cases is perceived upon the superficies of plants, enters also into the composition of the epidermis, as represented in *fig. 3. Plate I. Vegetable Anatomy.* These small tubes are however, upon close inspection, found to be composed of cells very much elongated, from whence it would appear, that the cellular substance is alone fitted for producing the epidermis of vegetables. The manner in which the cellular tissue is converted into cuticle, is probably beyond the reach of investigation; but that it is not the mere result of exposure to the air, is sufficiently plain from the facts already noticed. Like many other of the changes and operations of organic matter, we are unable to discover its immediate efficient cause, and in such cases, we must be content with observing the phenomenon, and stating it as the effect of a law of the system.

The growth of the cuticle is subject to considerable variety, according to the plant to which it may appertain, or the different parts of the same vegetable: thus, on leaves, flowers, fruits, &c. we do not meet with the successive layers of dead epidermis that exist upon trunks and branches. Some vegetables again have greater accumulations of dead cuticle than others; some get rid of these by repeated exfoliations; the plantane casts its cuticle every year; the epidermis of herbaceous plants and those which are not perennial, is always most delicate in its structure.

The epidermis presents no peculiarities in the monocotyledons, or those plants with one femoral leaf.

The uses of the external or cuticular portion of the bark have been much contended, although many of these are exceedingly obvious: it is evident that it serves as a defence to the whole surface of the vegetable; and accordingly we find its composition and strength dependent upon the functions which each part of the plant performs, and the injuries to which it is liable; on the roots it is tough and flexible; on the trunk rough, thick, and unyielding;

on the leaves, flowers, and such parts as are only to possess temporary existence, and which at the same time exercise important functions, the cuticle is thin, delicate, and soft. The epidermis serves to guard the plant against the effects of meteors; it likewise assists to moderate the operation of heat and cold, and thereby contributes to the maintenance of the equality and independence of vegetable temperature; it regulates the action of light upon the cellular tissue, and thus co-operates in the fixation of that subtle matter; but the most important, perhaps, of all its uses is the giving passage both to the fluids absorbed for the nutrition of the plant, and those expelled by transpiration, &c. Besides these known offices of the cuticle, others are ascribed to it. Many authors imagined that it restrained the growth of the whole tree; this however is disproved by the simple experiment of removing a portion of the cuticle, when it has been found that no bur or swelling took place; those trees also which are most distinguished for the cracks of the cuticle, are not observed to grow faster than others. For a further account of the functions of the cuticle of vegetables, see EPIDERMIS, LEAVES, ETIOLATION, TRANSPIRATION, INHALATION, and PORES.

The cellular envelope. This was the name given by Du Hamel to the cellular substance immediately under the cuticle, in consequence of its extending over every part of the plant; by Grew it was called parenchyma; and Mûber, whose abilities have been already mentioned, has with propriety made a distinction between the cellular tissue immediately next the cuticle, and that which is continued into the cortical layers; the first he terms the *herbaceous tissue*, the other the *parenchyma*.

The *herbaceous tissue* is a composition of cells of an hexagonal figure, so applied to each other that each of the sides assists in forming the parietes of the adjoining cell, precisely like the construction of a honey-comb. The membranes composing these cells are extremely fine and transparent. See *fig. 4. Plate I. of Vegetable Anatomy*, in which the cellular structure is highly magnified, and also some foramina or pores, which establish a communication between the several apartments. These pores are not above the 300th part of a line in diameter. In some instances, the cells are elongated, especially in the parenchyma of the monocotyledons, which is exhibited in *fig. 5. of Plate I.*; and it is remarkable, that in proportion as the vesicles become elongated the pores of communication are more frequent and regular. In some cases, where the cells are very much elongated, they are arranged in rows succeeding each other by intervals, which are perfectly regular. (See GLANDS, and PORES.) The cellular tissue has been described, by some writers, as composed of a number of fibres, interwoven like the texture of felt. Hill says it only differs from the epidermis in having its parts more distinct; and Malpighi believed the cellular substance to be made up of distinct vesicles, collected together, which he called utricles, but, as we have already said, this is not the case; the whole being one continuous membrane, every part of which enters into the construction of two cells. Grew compared the cellular substance to the bubbles observed upon the surface of fermenting liquors, which is a very happy similitude, inasmuch as it conveys a very perfect idea of its appearance when only examined with a single lens; but when the highest magnifying powers are employed, the hexagonal figure of the cells becomes evident. The herbaceous tissue is the immediate cause of the colour of the epidermis, and its own colour, again, depends upon that of the fluid contained in the cells, which is usually green, but is sometimes brown, red, yellow, &c. This juice is of a resinous nature, which circumstance would appear, as well as the colour, to be the effect of its continual exposure to the light.

light. It is probable that the sap is originally deposited in the cells, in the state in which it is absorbed, that is, consisting of water and carbonic acid gas, and that there, by the agency of light, it undergoes a decomposition; the oxygen contained in both the water and fixed air being discharged by the pores of the cuticle, the carbon of the carbonic acid, and the hydrogen of the water producing the oils and the resins. A number of consequences arise from this operation, not only to plants themselves, but to the animal world, which make it the most important process carried on in the vegetable system. See **ETIOLATION, LIGHT, OXYGEN, and TRANSPARATION.**

Parenchyma. This part is composed of cells like those described in the herbaceous tissue; indeed, the only difference which exists between these two parts of the cellular substance, is in the colour of their contained fluid; the one being usually green, in consequence of its exposure to the light; whilst the other, not being situated so superficially, is generally found transparent. In other respects, they agree in structure, and appear to be formed of the continuation of the same membrane.

The parenchyma of Mirbel corresponds with the tissue cellulaire of Du Hamel, the utricles of Malpighi, and the parenchymatous substance of Grew; whilst the herbaceous tissue is more strictly the envelope cellulaire of Du Hamel.

The parenchyma is not confined to the superficies of vegetables; it passes between the fibres of the cortical and ligneous layers, and forms the pith or medulla; the pulpiness of leaves and petals depends upon its existence; fruits, seeds, and the embryo plant, are almost entirely composed of it; bulbous, and other succulent roots, owe their bulk to it; no other structure is observable in the fungi and fungi; in short, the cellular tissue is the first and simplest state of vegetable organization, and serves as the connecting medium between all the parts of the plant.

There is, strictly speaking, no circulation of the juices contained in the cellular tissue; fluids, however, being admitted into any of the cells, easily pass into the neighbouring ones, by means of the small pores of communication, already described.

The texture of the cellular substance is very speedily broken down by maceration, or boiling in water; which circumstance should be recollected in preparing the parts of plants for examination; otherwise the natural connections, which are produced by the cellular tissue, may escape observation.

The Cortical Layers and Liber. When the epidermis and the cellular envelope have been removed, the remainder of the bark appears to be made up of a number of reticulated fibres, containing cellular substance in their interspaces; this appearance of the cortical fibres is plain to the naked eye, especially if the cellular tissue, which passes amongst them, be at all destroyed by maceration, or other means; but if examined by the microscope, these fibres become very distinct; their arrangement is then perceived to be singular, and difficult to describe. The fibres in their course, although longitudinal with respect to the plant, are not parallel with each other; each makes a slight curve, and thus comes into contact with the one adjoining, with which it usually becomes incorporated or united, and thus produces a plexus or network, which was called by Du Hamel the cortical plexus; sometimes these fibres merely touch each other, and then go off again, to compose another mesh in the plexus, see *fig. 6. Plate I. of Vegetable Anatomy*; *aaa* point out the reticulation produced by the fibres, and *bbb* the meshes, or spaces left between them. The meshes are not vacant in the recent vegetable, but filled with cellular tissue, which admits of the transverse motion of the fluids in plants. Du Hamel states,

that upon examining these fibres by a high magnifying power, each appeared to be a fasciculus, the fibres of which could be again resolved into fibres, and these again could be divided into others, until they became too minute for observation; i.e., however, as well as other authors upon the subject, suppose the cortical fibres to be vessels. See **VESSELS.**

The cortical layers, as the term implies, are not single, but consist of a number of concentric layers, placed upon each other in such a manner that the meshes of one plexus are situated opposite to those of another. *Fig. 7. Plate I.* exhibits this circumstance as it has been represented by Du Hamel. The cellular tissue passes through all these meshes, and thus produces a kind of intertexture, which Malpighi compared to cloth, calling the longitudinal fibres the warp, and the transverse the weft.

The meshes of the several net-works are smaller, the more internally they are situated; the gradation in this respect is regular from the external layer to the wood, as may be perceived in *fig. 8, 9, 10. in Plate I. of Vegetable Anatomy.* In the most internal plexus, *fig. 10.* the longitudinal fasciculi are nearly parallel, and so close to each other that the interspaces are almost obliterated.

The cortical layers, or net works, are found to increase in number according to the age of the part which sustains them. Thus Du Hamel reckoned only five or six plexuses upon the upper branch of the linden-tree, and seventeen at the base of the trunk of the same tree.

The same disposition of fibres does not exist in all plants; in the lagetto, or the lace bark tree, for instance, the cortical plexus exhibits a texture like gauze or lace. See *fig. 11. Plate I. of Vegetable Anatomy.*

Much confusion may be observed in the descriptions which authors have given of that part of the bark called *liber*. The name would appear to have taken its origin from the likeness which the cortical plexuses, when partially separated, bear to the leaves of a book; and, conformably to this idea, Grew and others have considered all the cortical layers as belonging to the liber; whilst, on the other hand, Malpighi has given this name to the innermost layer only. The liber is, however, generally allowed to be the most important part of the bark, and is that substance from which the cortical layers are formed. When the bark is stripped off a tree in a state of full vegetation, in a very short time a gelatinous substance is observed to exude upon the surface of the wood; this substance acquires organization, and is converted into a new bark. It was termed *carbium* by Du Hamel; the manner in which it is produced, and its composition, are both unknown, but its high utility in the vegetable economy is proved by some beautiful experiments. This formative or organizing substance is constantly renewed during the period of vegetation, and immediately produces the liber, which is insensibly converted into the layers of bark, and the alburnum, or white imperfect wood, which is next the bark; and hence the accessions of bulk in perennial vegetables, which are made every year, and indicate the age of the tree. That the liber is the immediate source of both the wood and the bark, or the central point or fountain of organization, is proved by two very elegant experiments made by Du Hamel. He separated a portion of the bark of a plum-tree, and made sure that it possessed the inner cortical layers or liber; he then removed a similar portion of bark from a peach-tree, and replaced it with the piece taken from the plum-tree. The graft perfectly succeeded; and upon a future examination he found, that not only the engrafted bark continued to grow, but that a corresponding portion of wood was produced, which was very distinguishable from the

the rest of the tree, as it possessed the red colour of the wood of the China-tree, from which the bark had been removed. The other experiment is equally decisive; he passed several silver wires through the bark of a tree, in the season of full vegetation, some of the wires only went through the parenchyma, whilst others were inserted into the liber; those which had only penetrated the cellular tissue, obeyed the eccentric progress of the bark, and as the tree grew came nearer the surface; but the wires which had passed through the liber, were carried towards the centre, and after some years, were found covered with many layers of wood.

The conclusion which Du Hamel drew from these experiments was, that the bark produced the liber, the albumen, and the wood; but it is Mirbel's opinion, that the wood in giving origin to the cambium, produces the liber, which is finally converted into both the bark and wood. For the further discussion of this subject, see CAMBIUM, LIBER, and WOOD.

It should be observed, that the period of vegetable existence depends upon the power of the plant to produce the cambium, and consequently, the liber; accordingly, in herbs, most of which do not survive one or two years, the successive layers which characterise the wood of trees, are not to be seen.

Hitherto we have been describing the arrangement of the cortical layers, in the Dicotyledons; in those plants, however, which are called monocotyledons, or having one seminal leaf, the disposition of these parts is very different; only the cuticle and cellular substance are found on the surface of these vegetables; there are no concentric layers of either bark or wood; the interior of the plant is filled with parenchyma, in which are contained the woody fibres, scattered at irregular distances; the cambium is deposited round each fibre, and there produces the tubular and cellular tissue; the tubular tissue forms first the porous wood or albumen, which contracts in thickness, elongates and is insensibly converted into the perfect wood, and in contracting is detached from the parenchyma and leaves a vacancy which is presently filled up by a new cambium; each of these fibres, therefore, might with propriety be considered as a distinct vegetable, inasmuch as it has the means of an independent growth. See CAMBIUM, WOOD, MONOCOTYLEDON, and DICOTYLEDON. It has already been observed, that some of the more simply organized vegetables, such as the fungi and fungi, do not possess in any of their substance either cortical or woody fibres, but are altogether composed of the cellular tissue.

After the account which we have given of the different parts entering into the structure of the bark, it is unnecessary to insist upon its uses in the vegetable system; in it reside almost all the powers and energies of the plant; wounds only are healed by it; upon the exact contact of the liber of two trees depends the whole of the success in engrafting; and in the bark are prepared not only all the juices and secretions which are required for the fullness and increase of the plant, but those peculiar substances which are applicable to so many of the purposes of common life and of medicine. See VESSELS, SUCCA PROPRIA, and SECRETION.

BARK, *Peruvian*, *Cortex Peruvianus*. The high importance in medicine of the peruvian bark has appropriated to it exclusively the term of the bark. We shall describe it under the botanical and now official name of CINCHONA.

BARK, in *Agriculture*, a substance frequently employed by cultivators as a manure to particular kinds of land.

The bark of trees in general, and particularly that of the oak, becomes an useful manure after it has been employed by the tanner in the preparation of leather. One load of oak bark laid in a heap and rotted after having been thus

used, it is said, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung. Mr. Miller in his Dictionary observes, that it is much better for cold strong land than for light hot ground, if it be used alone as taken from the tan-yard; because it is of a warm nature, and it will loosen and separate the earth so effectually, that, by only employing it two or three times, a strong soil, not easy to be wrought, may be rendered perfectly light and loose; but by mixing it with earth of a nature contrary to that which it is intended to correct, and in a proportion fitted to the nature of the soil on which it is to be laid, it will prove a good manure for almost any sort of land.

And Mortimer has even asserted that it will alter and change the very nature of the soil, and turn it into a rich black mould. As it abounds with vegetable matter derived from the tree to which it belonged, and is strongly impregnated with animal materials by the length of time which it has remained in the tan vats, in contact with the skins and hides of animals, it must necessarily prove beneficial as a manure where judiciously applied.

When laid on grass-land it has been recommended to be spread out over it soon after Michaelmas, that the winter rains may wash it into the ground to the roots of the grasses, as when laid on in the spring, it is apt to burn the grass, and, instead of improving it, to do considerable injury for that season. But when employed on arable land it should be applied and spread before the last ploughing, in order that it may be turned down lightly into the soil so as the fibres of the corn may easily reach it in the spring; when it lies too near the surface, it has however been supposed to forward the growth of the crop at too early a period, and to be nearly consumed in the spring, when the nourishment is chiefly wanted for its support.

In his work on gardening and agriculture, Mr. Bradley says, he advised a gentleman to whom a considerable quantity of bark was left, upon the expiration of the leaf of a tan yard, to lay some of it upon a piece of stubborn sour land; which he did with such success, that his product was admired by all the gardeners and farmers in the neighbourhood. For such soils, he thinks it should be mixed with a sandy mould or earth; and that one third of bark to two thirds of such materials will be a sufficient proportion for clays in general, laying on about one hundred and fifty cart loads upon the acre.

Worldige remarks, that the barks or rinds of other trees, though not of so high a value as that of the oak, which is the sort principally used by tanners, must of necessity enrich either corn or pasture grounds, if broken into small pieces, and laid upon them.

It has been found from experience, that by mixing caustic lime with tanners bark, in the proportion of about two parts of the latter to one of the former, the conversion of the bark into vegetable mould may be greatly promoted, and that the composition when employed as a top dressing for either turnips or grass proves an excellent manure, promoting the growth of the crops in a rapid manner.

BARK, in *Gardening*, comprehends the exterior parts or coverings of trees, plants, and vegetables, and also such substances in their dead state after being separated from them, and employed for different purposes.

The bark of trees, &c. is in itself of a hard porous texture, and adheres loosely to the liber, or inner bark. It is stated by Dr. Darwin, in his Philosophy of Gardening and Agriculture, that the barks of the trunks of trees are similar to those of their roots, and may be esteemed a part of them, as they consist of an intertexture of the vessels which descend from the plume of each individual bud to the radicle of it, and constitute its *caudex*. The bark of the root

is nevertheless, he says, furnished with lymphatics to absorb water and nutritious juices from the earth, and is covered with a moistened cuticle, while the bark of the stem is furnished with lymphatics to absorb moisture from the air, and is covered with a drier cuticle; the latter resembling the external skin of animals and the lymphatics which open upon it; and the former, the mucous membrane of the stomach, and its lacteals.

The interior barks of some trees, like the albumum or roots described above, contain, he thinks, much mucilaginous or nutritious matter; as the bark of elm (*ulmus*), and of holly (*ilex*), and probably of all those trees or shrubs which are armed with thorns or prickles, which are designed to prevent the depredations of animals on them, as the hawthorn, gooseberry, and gorse, *crataegus*, *ribes*, *graffularia*, *ulex*. The internal barks of these vegetables may, he thinks, be conceived to be their albumum less durated, and might probably all be used as food for ourselves or other animals in years of scarcity, or for the purpose of fermentation; as he doubts not but the inner bark of elm-trees, detracted in the spring by being boiled in water, might be converted by the addition of yeast into small beer, as well as the albumum of the maple and birch (*acer* and *betula*), all which are now suffered to be eaten by insects, when those trees are felled. For the sugar, which is extracted from the vernal sap-juice of the maple and birch, as well as that found in the manna ash (*fraxinus ornus*), seems, he observes, to reside during the winter months in the root or albumum, rather than in the bark properly so called, and to become liquefied by the warmth of the spring, or dissolved by the moisture absorbed from the earth and conveyed to the opening buds; but resides solely in the roots of perennial herbaceous plants: and in the economy of grasses, and he supposes of the sugar-cane, it is deposited at the bottom of each joint, which is properly at the root of the stem above it.

Of the above plants, continues he, the bark of the holly not only yields a nutritious mucilage, and thus supplies much provender to the deer and cattle in Needwood forest, by the branches cut off and strewed upon the ground in severe seasons of frost and snow, but contains a resinous material, which is obtained by boiling the bark and washing away the other parts of it. This resinous material possesses a great adhesiveness to feathers and other dry porous bodies, and has hence obtained the name of *bird-lime*, and much resembles the *casutebouc* or elastic resin brought from South America, and also a fossil elastic bitumen found near Matlock in Derbyshire, both in its elasticity and inflammability. Hollies may, he therefore supposes, be worth cultivating for this material besides the uses of their wood; as the doctor was informed, that thirty years ago a person who purchased a wool in Yorkshire, sold to a Dutch merchant the bird-lime, prepared from the bark of the numerous hollies, for nearly the whole sum given for the wood; which, if it could be hardened, might probably, he says, be sold for the elastic resin above mentioned. Whether this resembles the nutritive resinous material found in wheat flower, when the mucilage and starch are washed from it, might, he thinks, be also worth inquiry.

Other barks contain bitter, resinous, aromatic, or acid materials, which supply the shops of medicine, as Peruvian bark, cascarilla, cinnamon, and were designed by nature, he supposes, to protect those vegetables from the depredations of quadrupeds or insects. Hence, says he, many trees, and even the wood of them, after it is dried and made into domestic furniture, is never devoured by worms, as the ma-

hogany, cedar, cypress; and hence many plants, as the fox-glove (*digitalis*), hoand-tongue (*ynoziffum*), henbane (*hyoscyamus*), and many trees, are not devoured by any animals, as their juices would be poisonous to them, or much disagree with their stomachs, if their disgusting flavours to the nose or palate did not prevent their eating them. The same defence of the vegetable kingdom from human digestion, except those which have, in long periods of time, been selected and cultivated, appears, he remarks, from the relation of some unfortunate shipwrecked travellers, who have passed some hundreds of miles along uninhabited countries almost without finding an edible vegetable production.

Other barks contain retringent or colouring particles, employed in the arts of dying and tanning, as that of the barberry, oak, and ash (*berberis*, *quercus*, *fraxinus*). The art of tanning consists in filling the pores of the animal mucous membrane with these retringent particles found in some vegetables, which are believed to possess a quality of shortening animal fibres. Thus, when a long hair is immersed some time in a solution of the bark of oak, or of the galls produced on its leaves by the punctures of insects, the hair is said to be shortened. Whether this process be occasioned by the chemical coagulation of the mucus, of which these fibres totally or in part consist, or by capillary attraction tending to distend these fibres in breadth, and thus to shorten them, as a twisted string is shortened by moisture, has, he says, not yet been well investigated. By thus impregnating the pores of animal skins with vegetable particles they become less liable to putrefaction, as consisting of a mixture of animal and vegetable matter, as well as much better adapted to many domestic or mechanical purposes.

The art of dying consists likewise in impregnating the pores of dry substances with a solution of the colouring matter extracted from vegetables by the capillary attraction of these pores to the coloured solution; and, secondly, by a chemical change of those colouring particles after they have been imbibed, and the water of the solution exhaled, by again steeping them in another solution, which may chemically affect the former. Thus, says he, as green consists of a mixture of blue and yellow, it may be best produced by boiling the material designed to be dyed, first in a decoction of one of these colours, as of indigo, and then in that of another, as of the bark of barberry. And as a solution of iron becomes black when mixed with a decoction of oak-galls, by being in part precipitated; it is probable that the particles of this combination, of a solution of iron with retringent matter, may be larger than either of these particles separately; and, therefore, that if a dry porous substance be immersed, first in a decoction of oak-galls, and, after being suffered to dry, is then immersed in a solution of iron, the black tinge will penetrate into minuter pores, and thus become more intense than if the substance had been immersed in the black dye already prepared.

Other barks are, he adds, used for apparel, paper, cordage, and for many mechanical purposes, owing to the strength and tenacity of their fibres, or to the fineness of them; as hemp (*cannabis*), flax (*linum*), for the purposes of spinning and weaving. The bark or leaves of the papyrus, a flag of the Nile, was, he says, first used for paper; and the bark of the mulberry tree is still made into cloth at Otaheite, and other southern islands.

The art of separating the fibres of the bark of plants, as they consist of the caudexes of buds, or the connecting vessels between the plumules and the radicles of them, is, he observes, performed by soaking them some weeks in stagnant water, till the mucous membranes, which connect

these

these fibres, are destroyed by putrefaction; and afterwards by drying them, and beating off with hammers what may still adhere.

These fibrous parts of the barks of trees, as they contain no saccharine matter, like the albumum, are, he observes, much less liable to decay than the sap-wood, or perhaps than any part of the timber. Maupertuis, he adds, who went to Lapland to measure a degree of the meridian, says, that among the numerous trees which lay upon the ground, destroyed by age, or blown down by the winds, many birch trees appeared whole, owing to the undecayed state of their bark, but crumbled into powder on being trod upon; and that the Swedes took the practice from this of covering their houses with this unperishable bark, on which they sometimes lay soil, and thus possess aerial gardens.

To increase the quantity of bark, it must, the doctor remarks, be remembered, that the leaf-buds, or viviparous offspring of trees, as they form new buds, acquire new caudexes extending down into the ground, and thus increase the bark of the stem in thickness; but the flower-buds acquire no new caudexes, but die as soon as they have ripened their seed, and consequently do not increase the thickness of the bark. Whence one method of increasing the quantity of the bark is to increase the number or vigour of the leaf-buds, in contradiction to the flower-buds, which may be done by pinching off the flowers as soon as they appear; and as the bark becomes gradually changed into wood, this may be one method, also, he thinks, of forwarding the growth of timber-trees.

It is added, that the method of preserving the bark of trees from moss consists in rubbing off that parasite vegetable in wet weather, by means of a hardish brush; which is said to be used with advantage on the apple-trees in the cyder countries; and may, at the same time, give motion to the vegetable circulation, or forward the ascent of their juices absorbed by the radical or cortical absorbents. In dry weather, the brush should be frequently dipped in water. Washing the barks of wall-trees by a water-engine, may also facilitate the protrusion of their buds in dry seasons; and might possibly prevent the canker, if applied to dwarfs or espalier apple-trees. Other parasite vegetables must be occasionally destroyed where they occur; as the lichens, fungi, milletoe, with the ivies and other climbers, as some kinds of *Ionicera*, *clematis*, and *fumaria*, woodbine, virgins-bower, and fumitory.

It is further remarked, that when a wound is made in the bark of a tree, so as to expose the albumum to the air, the upper lip of the wound is liable to grow faster downwards than the lower one is to grow upwards, owing to the former being supplied directly with nutritive juices secreted from the vegetable blood after its ventilation, and consequent oxygenation in the leaves; whereas, the lower lip only receives those juices laterally by the inoculation of vessels. Over these wounds the cuticle is liable to project, and to supply a convenient hiding-place for insects, which either eat the new fibres of the growing bark, and perforate the albumum; or by their moisture, their warmth, and their excrements, contribute to the decay of the albumum, and prevent the healing of the wound. These dead edges of the projecting bark or cuticle should therefore, it is said, be nicely cut off, but not so as to wound the living bark.

It is remarked, that plasters of lime or of tar with sublimate of mercury, have been recommended to preserve the wounded parts from the air, and from moisture, and from insects; but as all these materials are injurious to the fibres of the living bark, they should be used with caution, so as

not to touch the edges of the wound, but only to cover the albumum; for this purpose, white lead and boiled oil, mixed into a thick paint, or with the addition of sublimate of mercury, or of arsenic, or of spirit of turpentine, may probably answer the purpose; and may be of real utility on the wounds of those trees whose wood contains less acrimony, and is therefore more liable to be bored into and eaten by a large worm or maggot, almost as thick as a goose-quill; which the doctor has seen happen to a pear-tree, so as to consume the whole internal wood, till the tree was blown down.

In respect to the caution necessary to be observed in not touching the living edges of the wounded bark with such materials as may injure the tree by their absorption, he remembers seeing several young elm-trees which died by their holes having been covered, as he was informed, by quicklime, mixed with cow-dung, to prevent their being injured by horses; and he has seen branches of peach and nectarine trees destroyed by sprinkling them, when in leaf, with a light solution of arsenic, and others with spirit of turpentine.

The composition recommended by Mr. Forsyth, in his "Treatise on the Culture and Management of Fruit Trees," which is constituted of cow-dung, effete lime, wood-ashes, and river sand, seems however to have been made use of in those cases with much advantage, and without any inconvenience having been experienced in this way.

It is further stated, by the author of Phytologia, that a more curious method of cure is said to have succeeded, where the bark of a tree has recently been torn off, even to great extent; and this is, by binding the same piece of bark on again, or another piece from the same tree, or from one of a similar nature, nicely adapting the edges of the bark to be applied to the edges of that which surrounds the wound of the tree, which, it is said, will coalesce, in the same manner as the vessels of the bark of an ingrafted scion, unite with those of the bark of the stock ingrafted on; which is strictly analogous to the union of inflamed or wounded parts of animal bodies, as in the cure of the hare-lip, or the insertion of the living tooth from one person into the jaw of another.

If the bark, over the cankered parts of apple-trees, adds the doctor, could be thus renewed by paring the edges of the mortified bark to the quick, and then nicely applying a piece of healthy bark, from an apple-tree of inferior value, and securing it with an elastic bandage, as a shred of flannel, it would be a very valuable discovery. Another method, where a branch of a valuable tree is in the progress of being destroyed by canker, might, he observes, be by inclosing the cankered part, and some inches above it, in a garden pot of earth previously divided, and supported by stakes, and tied together round the branch; which might then strike roots in the earth of the garden-pot, and, after some months, be cut off, and planted on the ground, and might thus be preserved, and produce a new tree; which experiment (the doctor says) he has tried on two apple-trees, and believes it will succeed.

Bark, in its dead state, after having been employed in the vat of the tanner, is found to be a material of great utility for the purpose of constituting those hot-beds in stoves and pits constructed for them, that are usually denominated *bark-beds*, and which from their being much more regular and durable in the temperature of their heat, than those formed from dung, become a great deal more convenient and useful for different purposes of the gardener; and are of course employed with much advantage in the growth and culture of various tender and curious

exotic

exoties that require the aid of an uniform degree of artificial heat in this climate. See BARK-BED, and BARK-PIT.

BARKS of Trees, (Chemical Analysis of). Since the time that chemists have introduced a considerable degree of minuteness and comparative accuracy in the analysis of vegetable matter, many of the general classifications of medical chemistry have been found inconvenient and liable to error. This is particularly the case when vegetable substances designed for chemical examination, are classed *anatomically*, or according to the uses which they fulfil in the economy of the plant, rather than the properties which they exhibit under the hands of the chemist. Thus, in the instance of the *Barks of trees*, scarcely any common chemical character can be assigned to them, as their composition varies in almost every order of plants, and as they partake largely of the qualities of the common juice which circulates in the vegetable. If there is any principle common to all barks, it is (besides water, an invariable ingredient in vegetable matter), the ligneous fibre or insoluble woody part, but even in this respect some very important differences occur in the several species which cannot be neglected by the chemist. The substances which render many barks peculiarly interesting in the arts and in medicine are, TANNIN, or the principle which causes several of them to be employed in the art of tanning; EXTRACT, a substance varying considerably in properties, and much used in medicine; and the GALLIC ACID, the basis of many of the black dyes and pigments when in conjunction with iron. These principles, however, are not peculiar to barks, but they are all found in other parts of vegetables. We have an example of an excellent analysis of the bark of the CINCHONA, by M. Foureroy, to which article we shall refer the reader who may wish to have a good specimen of the chemical analysis of vegetables.

BARKS, general observations relating to. From the experiments of M. Buffon, it appears, that trees stripped of their bark through the whole length of their stems, die in about three or four years. But it is remarkable, that trees stripped in the time of the sap, and suffered to die, afford timber heavier, more uniformly dense, stronger, and fitter for service, than if the tree had been cut down in its healthy state. Some thing of a like nature has been observed by Vitruvius and Evelyn. Mem. Acad. Scienc. 1738.

As animals are furnished with a panniculus adiposus, usually replete with fat, which invests and covers all the fleshy parts, and secures them from external colds, plants are encompassed with a bark replete with fatty juices, by means whereof the cold is kept out, and, in winter-time, the spiculae of ice prevented from fixing and freezing the juices in the vessels: whence it is, that some sort of trees remain ever green the year round; because their barks contain more oil than can be spent and exhale by the sun, &c. Ray's Wisd. of God, &c. part i. p. 103.

The bark has its peculiar diseases, and is infected with insects peculiar to it. Wounds of the bark often prove mortal. See CANKER.

There are a great many kinds of barks in use in the several arts: some in medicine, as the quinquina, or jesuit's bark, macer, chacarilla, &c. others in dyeing, as the bark of the alder; others in spicery, as cinnamon, cassia lignea, &c. the bark of oak in tanning; others on other occasions, as that of cork; that of a kind of birch is used by the Indians for canoes capable of holding twenty four persons.

Of the bark of willows and linden trees is ordinarily made a kind of ropes. The Siamese make their cordage of the bark of the cocoa tree, which is also the case in most of the Asiatic and African nations. In reality, flax and

hemp, with all their toughness, are only the sap-vessels, or ligneous fibres of the bark of those plants.

The ancients wrote their books on barks, especially those of the ash, and lina or lime-tree; not on the exterior or outer bark, but on the inner and finer, called philia; which are of so durable a texture, that there are manuscripts on it, still extant, a thousand years old.

In the East Indies they manufacture the barks of a certain tree into a kind of stuff or cloth. It is spun and dressed much after the manner of hemp. The long filaments separated from it, upon beating and steeping it in water compose a thread, of a middle kind between silk and common thread: neither so soft nor bright as silk, nor so hard or flat as hemp. See Neuman's Works, p. 428. note. Some of these stuffs are pure bark, and are called pinasses, Lam-bones, &c. In others they mix silk with the bark, and call them gingham and millas: the fountalunges too are part silk, part bark, and are only distinguished by being striped. The Japanese make their paper of a species of mulberry tree. (See MORUS.) In the island of Otaheite, the natives make their cloth, which is of three different sorts, from three different kinds of bark; that of the mulberry tree, that of the bread-fruit tree, and that of the cocoa tree. That made of the mulberry is the finest and whitest, and worn chiefly by the principal people. It is manufactured in the following manner. When the trees are of a proper size, they are drawn up and stripped of their branches: after which, the roots and tops are cut off; the bark of these rods being then slit up longitudinally is easily drawn off; and when a proper quantity has been procured, it is deposited in some running water to soak, and kept down by heavy stones; when it is supposed to be sufficiently soaked, the women go down to the brook, and, stripping themselves, sit down in the water to separate the inner bark from the green part on the out side; for this purpose, they place the under side upon a flat smooth board, and with a kind of shell scrape it very carefully, dipping it continually in the water, till nothing remains but the fine fibres of the inner coat. Being thus prepared in the afternoon, they are spread out upon plantain leaves in the evening, and placed in lengths of about eleven or twelve yards, one by the side of another, till they are about a foot broad, and two or three layers are also laid one upon the other; care is taken that the cloth shall be in all parts of an equal thickness, so that if the bark happens to be thinner in a particular part of one layer than the rest, a piece that is somewhat thicker is selected to be laid over in the next. In this state it remains till the morning, when a great part of the water which it contained, when it was laid out, is either drained off or evaporated, and the several fibres adhere together, so that the whole may be raised from the ground in one piece. It is then taken away and laid upon the smooth side of a long piece of wood, prepared for the purpose, and beaten by the women. The instrument used for this purpose is a square wooden club, having each of its four sides or faces marked, lengthwise, with small grooves or furrows of different degrees of fineness; those on one side being of a width and depth sufficient to receive a small packthread, and the others finer in a regular gradation, so that the last are not more than equal to sewing silk. They beat it first with the coarsest side of this mallet, keeping time like our smiths; it spreads fast under the strokes, chiefly, however, in the breadth, and the grooves in the mallet mark it with the appearance of threads; it is successively beaten with the other sides, and last of all with the finest, and it is then fit for use. Of this cloth there are several sorts, of different degrees of fineness, in proportion as it is more or less beaten; and the other cloth

also differs in proportion as it is beaten, and the several cloths differ also from one another in consequence of the different materials of which they are made. The bark of the bread-fruit is not taken till the trees are considerably longer and thicker than those of the mulberry; the process afterwards is the same. Of the bark of a tree which they call "pocou," the "*hibiscus tiliaceus*" of Linnæus, they manufacture excellent matting; both a coarse sort on which they sleep, and a finer which they wear in wet weather. Of the same bark they also make ropes and lines, from the thickness of an inch to the size of a small packthread.

BARK Indian, *Thuja cortex*, a medical bark, brought from the East, rolled up like cinnamon, of a rusty color, a warm aromatic, bitter taste, and pleasant smell; sometimes used in fumigation against fits of the mother.

BARK-Mills. See MILL.

BARK, Grafting in. See ENGRAFTING.

BARK, in Navigation, denotes a little vessel for the sea, usually with pointed or triangular sails, in number two, or three at the most. The term is usually appropriated by seamen to those small ships which carry three masts without a mizen top-sail. Our northern mariners in the coal-trade, apply the term to a broad-sterned ship, which carries no ornamental figure on the stern or prow. Bark is also a Mediterranean vessel, with three masts and no bowsprit; the foremost rakes much forward and carries a latteen sail; the main-mast is a pole-mast, and carries three square sails, like the polacre; the mizen-mast is small and carries a mizen and a top-sail. Fishing-barks are small vessels with one mast, used for fishing, &c. by the Spaniards: on the mast they carry a square main-sail, with a jib upon the bowsprit. Japanese barks are vessels similar to junks, 80 or 90 feet long on one deck, which have only one mast, that carries a square-sail, and forward one or two jibs made of cotton. They only use sails, when the wind is large. Barks of Cracalou and Straits of Sunda are vessels with flush-decks, high steer, and sharp forward. They have one mast, and the sail is similar to the Caracores, being long and narrow. These vessels are kept from upsetting by a fort of beams crossing the vessel and bending downwards at the ends, which fasten to a long round or flat piece of timber. Bombay-barks are called DINGAS. See PLATES OF SHIPS.

The word *Bark* is derived by some from the Latin *barca*; by Fournier, from *Barce*, a city in Africa; and by Toienatus, from *Barcelona*.

Some authors use the word bark for any vessel that has no masts.

BARK, Armed, a kind of fire-ship filled with soldiers, used both for making sallies, and to attack galleries, and bar the passage over them.

BARK, Long, is a small vessel without deck, longer and lower than the common barks, being sharp before, and commonly going both with sails and oars. It is built after the manner of a sloop, and in many places is called a *double sloop*.

BARKS, Water, are little vessels used in Holland for the carriage of fresh-water to places where it is wanting, as well as for the fetching sea-water to make salt of. They have a deck, and are filled with water up to the deck.

BARK-Bed, in Gardning, that sort of hot-bed which is either wholly or principally constituted of tanner's bark. This sort of bed, from its preserving the most uniform and regular degrees of heat, is found by much the most useful in the propagation and culture of all kinds of tender exotic

plants that are brought from warm climates, and which stand in need of the continued assistance of artificial heat in this part of the world. Beds of this nature, with a little trouble in the management of them, are found sometimes to support a pretty uniform and regular temperature for a considerable length of time.

These are the kind of hot-beds that are generally employed in hot-houses, being formed in pits or cavities constructed for the purpose in them, frequently the whole length of the houses, six or seven feet in width, and three in depth, being inclosed by means of brick work. See BARK-PIT.

In these beds, the pots of such tender exotics as have been mentioned, are plunged and supported; and they at the same time afford assistance in supplying such houses or stoves with those degrees of heat that may be proper for the growth and support of various other plants that do not require to be plunged into the beds, the heat of the surrounding air, produced in this way, being sufficient for their growth and preservation. Thus, by the aid of bark-heat, and that of fire during the severity of the winter season, the gardener is enabled to imitate, within the hot-house, the temperature of distant climates, and not only to cultivate and bring to perfection the *Bromelia Acanas*, or pine-apple, but also various other tender plants from different quarters of the globe, both of the herbaceous and woody kinds, and to exhibit them in their most healthy and beautiful states in this country.

Bark hot-beds are likewise occasionally formed in pits constructed for them, in the open ground, separately and detached from the hot-house. These are walled round with bricks chiefly above the surface of the ground, having a frame or coping of wood upon the top on which glass lights are fixed so as to slide with facility. See BARK-PIT.

In these pits the bark-beds are made to the depth of three feet or more, in order to afford an uniform and lasting heat, for the purpose of raising and propagating different sorts of tender plants from seeds, suckers, layers, cuttings, &c. both of the stove and green-house kinds, as well as those of the natural ground. Such beds are of course of great utility where there are large collections of tender exotic plants, and as nursery-pits for young pine-apple plants to supply the stove or pinery annually. See STOVE.

Beds formed of bark are also employed with success in raising various sorts of early productions of other kinds, as early strawberries, melons, peas, French beans, &c. which by the regular and moderate heat which they afford are moisterly brought forward in the greatest perfection. They are likewise made use of in forcing different sorts of curious flowers, both of the bulbose, tuberose, and and fibrous rooted kinds, into early bloom; as hyacinths, dwarf tulips, narcissus, jonquils, anemones, ranunculuses, pinks, &c. also many flowering plants of the small shrubby kind, as roses, hypericums, &c.

Bark-beds are also employed with great advantage in forcing frames for the purpose of producing early fruit of the apricot, peach and grape kinds. See FORCING FRAMES, and HOT-WALLS.

Hot-beds constituted of bark from the slow and regular manner in which the heat is in common evolved, are not so liable, as those of dung, to injure the plants by their steam; they are therefore to be preferred for all the more important purposes of forcing where the material can be obtained.

The heat of them may be perpetuated for a great length of time, by having recourse occasionally to the practice of forking or turning them over, adding in such operations about a third part of new tan or bark. The beds are how-

ever to be wholly, or in a great part, renovated every autumn or spring.

There are different sorts or sizes of bark made use of for the construction of these beds, as coarse, middling, and small. The first kind is the longest in taking on heat, and is apt to heat violently at the beginning, but is of the longest duration. The second sort heats sooner, is more regular, and pretty durable in its effects. But the last kind heats the quickest, yet it is the weakest, and soonest becomes earthy, consequently the least proper for the purpose. Where there is a choice of the material, the middle sort, or a mixture of it and the coarse, should constantly be preferred, admitting as little of the small as possible, and care should be taken that it be perfectly fresh from the vat of the tanner. When the bark is wet after being brought home, it is a good practice to throw it up into heaps or ridges for a few days, in order that it may be drained and rendered more dry, as without such precaution the process of fermentation may be too much retarded.

The periods of making beds of this nature must be regulated by circumstances; but where they are intended for pine-apple plants, they should be prepared about the latter end of September or beginning of October, in order that they may afford a good heat during the winter season: but when the raising of plants from seeds, cuttings, &c. or the forcing of culinary vegetables, and fruits or flowers, are the principal objects, the spring may be the most suitable time, as in January or March. For particular uses they may, however, be made at any period.

In forming the beds, the tan or bark, prepared as above, is thrown into the pits that are constructed for it; and where there is old, the new bark well mixed and blended with it, by means of the tan-fork, quite to the bottom; then it is the practice to begin at one end and carry them on to the full breadth and depth, without treading upon them, as that would render the bark too solid for the process of fermentation. It is necessary to raise the surfaces of the beds about three or four inches higher than the tops or copings of the beds or pits, in order to allow for the settling that may take place. In the making of this sort of hot-beds for the purpose of raising pine-apples, the author of the "Scotch Forcing Gardener," in order to avoid the danger of too much bottom heat, never admits of the tan being sifted, or of more than one eighth part of new tan being added, which is introduced by skimming off a portion of the old tan from the surface; by this means the new tan is not suffered to come within a foot of the surface of the bed, and of course the pots are entirely plunged in the old tan. It is his general practice to deposit half of the quantity of new tan that may be added, in the bottom of the trench, and blend the other half equally with the old, till within a foot of the top of the bed. And in trenching over the beds, it is his custom to throw the sides to the middle, and the middle to the sides, in order that the old tan may be incorporated in an equal manner with the new.

It is contended, that in this manner of preparing the beds, they will be "of a mild and equal temperature from the first, and continue much in the same state for three or four months;" and that after the first filling, they will be attended with but little expence for new tan. It is obvious that the filling the pits of new pinceries, in the above intention, should either be performed some time before the plants are to be introduced, or the tan be well sweated down and reduced by frequent turning over in an open shed or other convenient place; and in these cases it is even advised not to plunge the pots more than half their depths into the beds for the first two or three months after they have been filled.

The new bark or tan that is to be added should constantly be thrown up into heaps for eight or ten days before it is employed, in order that it may drain and facet; as when used while wet from the tan pit, it is apt not only to cake in the beds, but sometimes to heat violently.

It is necessary, as soon as the beds have been made, to thrust sticks into the bark in different parts, in order that they may be drawn up occasionally to ascertain the heat of them.

The beds, in the first method of making them, will in general be of a proper temperature for the reception of plants in about ten days or a fortnight, as the examination of the sticks will shew. If they be intended for pines or other plants that require pots, they must be plunged immediately into the bark, no earth being necessary as in other sorts of hot-beds; and in performing this business, it is of utility to have a board placed across the beds or pits to stand or kneel upon, and thereby prevent the bark from being trodden too close. The pots containing the plants must be placed to suitable depths, according to the differences in the degrees of heat in the beds, in order to be ultimately let down to their rims. When the heat of the beds is shown by the trying sticks to be on the decline, it will be proper to restore it by stirring up or turning over the bark, which, when of the large or middle sort, will seldom require any increase of new tan.

In accomplishing this business, it may be performed either in the manner directed above, or, after removing the pots, by beginning at one of the ends, and forking up the whole of the bark to the bottom, afterwards breaking the lumps and turning all the bark over, the pots with the plants being directly restored. The same operation is to be repeated as often as the decline of heat may render it necessary, and such additions of fresh bark be made as may be required, but in common, not more than two or three turnings are requisite. The additions of fresh tan should mostly be made about the beginning of March or April, the crumbly earthy parts of the old bark being cleared away.

The making of new beds is mostly performed as has been seen above in the autumn, about September or October, as after they have remained ten or twelve months, the bark is much exhausted both in heat and substance, and becomes earthy. This earthy part is to be now separated by means of the forken, and new bark added, the whole being well blended together with the fork. When the whole of the old tan appears earthy, it is the best method to clear the pit entirely, and make the bed up altogether of new bark. See **HOT-HOUSE**.

BARK-BLIND, a disease which has been supposed common to fruit and other trees, and to be capable of being cured by making a slit or opening through the bark, in a longitudinal direction, from the top of the tree or bough to the bottom, about February or March; and if the gaping be pretty considerable, to fill it up with cow-dung, or some other similar composition. This is probably not so frequently a disease as has been believed by gardeners, as the imperfect growth of trees often causes such appearances.

BARK-GALLING, is when trees are galled by thorns or by being bound to stakes, &c. It is cured by clay laid on the galled place, and bound on with hay ropes.

BARK-PIT, a pit or cavity of a long, square, or other form, a yard or more in depth, appertaining to a hot-house or stove, &c. and being formed internally, or detached externally, in which to make tan or bark hot-beds, commonly called bark-beds. The dimensions are four, five, or six feet in width, or more, having length in proportion to that of the hot-house, &c. and when in detached pits, such as may be required. 12

both methods they are formed by a low surrounding brick wall, about a yard in height in the internal pits, and in the external ones three or four feet in front, by four or five in the back wall. These different sorts of pits are indispensably necessary, where bark-beds are intended, to make the beds in, as the short loose nature of the tan will not admit of being formed into compact regular beds, without the aid of such kinds of inclosed pits to confine it close together within the limits that are requisite in the formation of the beds.

For various purposes, bark-pits are necessary in all hot-houses or stoves, and occasionally in forcing houses, &c. And detached bark-pits, distinct from the hot-houses, are likewise very useful in all extensive gardens on many occasions, being of great service in the culture of many sorts of tender exotics, and in raising various kinds under different methods of propagation; as well as for raising and nursing those of similar kinds in their young and tender growth; also occasionally for forcing and raising early productions of several sorts of hardy plants in the greatest perfection.

The bark-pit of a hot-house, &c. is an essentially necessary interior compartment, and which, as before observed, is the internal cavity wherein the tan or bark hot bed is made, extending lengthways, and occupying almost the whole bottom space of the house, except about two feet on each side and ends, which is reserved for an alley or walk round, between the outward wall and that of the pit, which should be but very little sunk below the general surface of the floor of the surrounding walk, and formed by a thin wall of brick-work, generally raised, the greater part, three feet high above the surface, the bottom being paved with brick or stone, &c. and in which the bark-bed being made to the whole width, length and depth, serves both to plunge the pots of the more tender exotics in, such as the pine-apple, &c. in order that they may receive the kindly moist heat thereof immediately about their roots; and, at the same time, to diffuse a peculiar beneficial warm vapour for heating the internal air, assisted by fire-heat in the flues in winter; but sufficient alone in summer and autumn; producing, from May till October, an effectual temperature of internal heat, for the preservation and growth of various tender exotic plants of the stove kind, natives of different parts of the hot regions of South America, Asia, and Africa. See BARK-BED, HOT-HOUSE, and STOVE.

Hot-houses, or stoves of the common width, have in general only one pit, extending lengthways of them as described above; but if they are of considerable extent in length, the pit is sometimes divided in the middle by an intervening passage, to render it more convenient in performing the necessary culture of the plants.

Some hot-houses, however, of very great width, have two internal bark-pits ranging parallel lengthways with an alley or passage extending between them, which renders them more commodious in giving the requisite culture to the plants that are plunged in the beds, than if the whole was in one extremely wide pit, in which it would often be very inconvenient to come at the plants placed towards the middle of them; so that two parallel pits, four or five feet wide each, become more eligible than one of eight or ten feet, and by having an intervening passage, give a larger scope and afford a better current of air, for the growth of the plants in the beds, as well as admit of viewing them to greater advantage and effect.

Detached or external bark-pits are exterior erections, separate and distinct from the hot-house or stove, but in some manner connected with, or appertaining to them, being, on many occasions, employed for similar uses, as well as for various other purposes, where occasional artificial heat is

wanted. They are, as has been observed, four, five, or six feet wide, having such length as may be required; formed by a surrounding wall of brick-work, three or four feet high in the front, by four, five, or six behind, where sometimes flues for winter fire-heat are erected in the upper part; the whole being covered at top with moveable glass frames, sloping southward to the full sun, and in which, a bark-bed being made to the whole width, length, and depth, becomes an useful appendage to the stove; assisting in the culture of various tender exotics of that repository, especially in the way of a nursery-pit, for raising and preserving them to some advanced state of growth; also occasionally in the propagation and protection of the more tender kinds of greenhouse plants, or any particular, curious, or tender exotic plant, of the full ground, as being always ready, and prepared with a continuing growing heat, wherein to plunge the pots, where artificial heat is required, or essentially necessary in raising such tender plants more effectually and expeditiously.

These kinds of bark-pits also prove exceedingly useful in raising many sorts of tender exotics from seed, suckers, cuttings, slips, &c. and in retaining and forwarding them in their growth for some time. Bark-pits of the same kind are likewise particularly useful and necessary in the culture of young *ananas* or pine-apple plants, in rearing and nursing them till of a proper age and size, to be placed in the succession-house, fruiting-stove, or pinery. See BROMELIA, ANANAS, and STOVE.

A similar kind of detached bark-pit is likewise occasionally used with advantage in the work of planting or transplanting, or shifting tender or curious plants in pots, for plunging the pots which contain them, as soon as re-planted, into, which much expedites their taking fresh root, and brings them up at first into a free and vigorous growth.

Bark-pits, of the same kind, are also successfully employed in the work of forcing and raising early productions, such as melon, kidney-beans, peas, strawberries, &c. and for many sorts of flowers, both of the bulbous, rooted, and herbaceous kinds, as well as for small flowering shrubs. And if the dimensions of them were increased, especially in height, in the back parts they might have several sorts of dwarf-fruit trees in pots for the production of early fruit, placed in them. See FORCING-FRAME.

Detached bark-pits should always be erected in warm dry situations, in a southerly aspect, and be constantly ranged lengthways in the direction of east and west, or nearly so, in order to have the whole front incline fully to the south sun, in a sloping manner, on which to place the glasses in the same position, being generally situated either contiguous to the hot-house or stove, but at a proper distance in front of it, as the situation and convenience of the place may admit. Or they may be erected at one or at both ends, extending in a line with it, but separated by a passage between them.

But detached bark-pits are sometimes formed with ridged tops, like the roofs of houses, the glasses sloping to both sides, being ranged lengthways north and south, in order to have the benefit of the sun equally on both sides, and used for the same purposes as the others; though the common south-fronting pits, extending east and west, are more generally adopted, being less expensive in glass-work, &c. and, in general, more convenient for different purposes of the forcing kind.

They should be constructed, as has been observed, with walls of brick work, forming the upright sides and ends nine inches thick; and where fire-flues are intended, the back wall should be of a proper thickness from the bottom, to admit of having flues in the upper parts, a fire-place being contrived externally at the bottom at one end; or, in considerably

siderably extended pits, a double fire-place may be formed in the middle, behind, or one at each end, either endways or in the back part, as may be thought the most convenient.

Some detached pits are formed of wood-work only, by means of post and planking, serving for particular occasions, where no fire heat is required, as flues for that purpose cannot be admitted in such kinds of pits; where additional heat is occasionally necessary, in such pits, it is effected by applying a strong lining of hot dung to the outside; by which a good constant heat may be supported. In these bark-pits, sometimes the younger pine-apple plants are deposited and nursed for the first year; they are likewise occasionally used for the purposes of propagating, raising, and nursing tender plants in spring and summer, &c.; also for forcing early excellent crops, flowers, &c.

The principal detached bark-pits should, however, be formed with brick-work walls; as being the most effectual for general use, and of the greatest duration.

At *fig. 1. Plate I. in Gardening*, is the representation of a bed or pit of the most common kind, which may be made use of either with bark or dung.

Fig. 2. exhibits a view of a bark pit upon a larger scale.

Fig. 3. is the plan and section of two nursing pits, as given by Mr. Nicol in the "Scottish Forcing Gardener," adapted equally to the purpose of striking young pine plants, and the forcing of asparagus, cucumbers, melons, strawberries, French-beans, salads, flowers, &c. In the plan they appear considerably sunk below the ground level for the convenience of shifting. But in wet situations this should not be the case, but a bank of earth raised against them in a sloping direction all round, as by this contrivance the front flues may be useful in raising early salads, by having the front borders properly prepared. The furnaces are placed behind communicating first with the front flues, and returning in the back singly. The surface of the bark-bed is level with the bottom of the flues all round, to prevent the danger of burning; and at the distance of two feet from the wall of the pit. The inner wall of the flue is formed a brick on edge, and the outer one a brick in bed, for the purpose of strength. The divisions of the plan are only each thirty feet in length, but they may be extended to forty, and be wrought by the same furnaces.

One length of fish is sufficient, as they are worked in the manner of the common hot-bed, having fastenings at top to prevent their slipping down.

Fig. 4. is the plan and section of a single pitted pine flue, on an improved construction, as furnished by the same author, for a fruiting or succession house. It is wrought by two fires, having a shed behind it which may be converted to various uses.

The bottom of the bark-bed is level with the surface of the ground, but the surface much elevated, that the sun and light may be admitted more freely to the plants.

Trellises for vines may be placed against the brick-wall and upright sashes in front.

Two lengths of sashes are here necessary in the roof. The under ones should be made to move either up or down.

Fig. 5. is a bark-pit for succession pine-apple plants.

BARKARY denotes a tan-house, or place to keep bark in, especially for tanners.

It is otherwise called a *leath-house* in old writers.

BARKING of Trees, in *Rural Economy*, the operation of stripping off the bark or rind, which, when taken from some kinds of trees, as the oak, elm, &c. is made use of by the tanners, and of course becomes an article of profit to the proprietor.

It is the most usual in this climate to perform the operation in the month of May, as, at that season, the bark, by the rising of the sap in great quantity, is the most easily separated from the wood. This, however, renders it necessary to fell the trees in that month; by which the timber is of much less value than it would be if they were cut down after the falling of the leaf.

It is remarked by Dr. Darwin, in his "Phytologia," that as the sap-juice rises in all deciduous trees during the winter months to expand their foliage, though probably in greater quantity in some trees than in others; it must consist, not only of sugar and mucilage, as in the maple and birch, but of various other ingredients in different trees, which have not been attended to; as appears from the taste of their young leaves, as of oak or ash. And as some of these materials reside in the roots and sap-wood, or albumum, so others of them may perhaps reside in the bark, where they have been deposited during the preceding summer, and become liquefied by the warmth of the spring, or dissolved by the moisture absorbed from the earth and air, and conveyed upwards to the opening buds; whence it is evident, he thinks, that the barks of trees should be taken off for use in winter, or in early spring, before their buds begin to expand; as then a part of those nutritious juices, or of the other materials which are required for medicines, or in the arts of dyeing and tanning, are in part expended on the young leaves, which generally possess the taste and qualities of the bark, though to a less degree. It may nevertheless be observed, he says, that all these astringent or other materials may reside in the albumum of the trunk or roots of all perennial vegetables, as well as in their barks; because the young leaves, which pullulate on decorticated oaks, have the same bitter flavour as the leaves on those which have not been decorticated; which may in part be derived from the bark of the root, which is still in the ground, and be carried up the vessels of the sap-wood to the new buds. Hence the bark of oak-trees should be taken off during the winter; but when the sap-juice, rising or ascending in the vessels of the albumum, becomes more liquefied by the warmth of the spring, or is mixed with moisture, and pushed up with great force by the absorbent vessels of the roots, it oozes out in some degree between the albumum and the bark; and thus the bark becomes so much more readily separated from the sap-wood; whence this business, as has been already observed, is generally done early in the spring, and should always be performed as soon as this facility of detaching the bark appears; because this process of the germination of the buds continues to injure the bark, whether the tree be cut down or not; as the buds expand their foliage on new felled trees, as they lie on the ground.

It is observed by Mr. Marshall, in his "Rural Economy of Yorkshire," that the peeling of oak timber in that country is generally done by the day, the labourers being, he believes, invariably employed by the timber-merchant, not by the tanner; practices which are, he conceives, productive of a considerable saving of bark. Men, says he, working by the ton or quarter, or tanners paying by weight or measure, will not induce them to peel the boughs sufficiently near; as it is against their interest to do it. But it is the interest of the timber-merchant, or of the tanner, if he purchases by the gross, or by the ton of timber, to peel to far or so long as the bark will pay for the labour. This, he thinks, accounts for the fullness of the timber which are peeled in that county; if the bark ran freely, it would be much thicker than the fingers are frequently stripped of their bark.

The tool commonly made use of for this purpose in most countries,

countries, is made either of bone or iron. If of the former, the thigh or rib-bone of an ass is preferred, which is formed into a two-handed instrument for the stem and larger boughs, with a handle of wood fixed at the end. The edge once given by the grinding-stone, or rasp, keeps itself sharp by the wear that afterwards takes place in the operation.

The method of drying bark in the above country is generally the common one of setting it in a leaning posture against poles lying horizontally on forked stakes. But in a wet season, or when the ground is naturally moist, it is laid across a line of top-wood, formed into a kind of bunklet, raising the bark about a foot from the ground. By this practice no part of the bark is suffered to touch the earth; and it is perhaps, upon the whole, the best practice in all seasons and situations. The bark is then put in stacks or houses, and generally shaved or chopped ready for the tan-pit, and afterwards sold to the tanner at so much the quarter. This custom, however, appears to be founded on a false basis; the tanner is the best judge of the mode of preparation, and the operation ought, therefore, to pass under his immediate inspection.

The practice of grinding bark does not seem to have yet got sufficient footing in the district mentioned above; whenever it does, Mr. Marshall observes, it will of course bring the preparation of it into its proper channel.

The price of chopped bark varies considerably, according to the quality and the circumstances under which it is placed.

Maliciously barking of apple-trees, or other fruit trees, is made felony by 37 Hen. VIII. c. 6.

By the French laws, all dealers are forbid to bark their wood while growing, on the penalty of 500 livres. This law was the result of ignorance; it being now found, that barking of trees, and letting them die, increases the force of timber.

BARKING is also a name given to the cry of dogs and foxes.

The term is also applied to certain quaint noises, made by sick persons in some diseases.

In cynic spasms, and epileptic fits, the patient sometimes snarls, howls, and barks, with all the notes of a dog. But it is in the *hydrophobia* that barking has been oftener observed; persons seized with this, are apt to rave, bite, snarl, and make a harsh noise in their throats, which is called barking.—Vide Phil. Transf. N° 280. N° 323. N° 207. and N° 242.

BARKING, in *Geography*, a market town in the county of Essex, seven miles from London, is so called from a creek on which it is situated. The town is of considerable extent, and chiefly inhabited by fishermen, from whom the fish-markets of London are frequently supplied. The parish is divided into the four wards of Barking, Great Ilford, Chadwell, and Rippleward, abounding with fertile lands and beautiful prospects. It was to this place that William the Conqueror retired, shortly after his coronation, till he had erected such castles in London as might awe the people whom he governed; and here the great barons Edwin and Morcar came and swore fealty. Very lately the remains of an intrenchment were visible at this place; but the plough has nearly obliterated the whole. Much land in the parish has been recovered from the rivers Thames and Roding. The second nunnery of the Saxons was founded at Barking by Erkinwald, fourth bishop of London, in 666, for Benedictines; the bishop placing his sister Ethelburga (afterwards canonized) as the first abbess. She was constituted lady paramount in all the manors within the half hundred of Becontice, and held of the king an entire barony, a privilege granted to only three other religious foundations in

England, those of Wilton, Shaftesbury, and Winchester. At the dissolution, the revenues of Barking abbey were estimated at 802l. 12s. 5d. A gateway and a great part of the wall of this magnificent structure still remain adjoining the church-yard. In the township of Great Ilford is an ancient hospital for lepers. The parish church is a large handsome structure, which formerly belonged to the abbey, but is now in the gift of the warden and fellows of All Souls college, Oxford.

The market is held on Saturday, and a fair on October 22d for horses; another fair is held yearly, on and round a famous oak denominated *Fairlop*, concerning which the following funnary may be acceptable. Many years since, Mr. John Day, a worthy but whimsical character in Wapping, used annually to dine with his friends on beans and bacon under the shade of this famous oak; hence arose the fair. *Fairlop oak* has sustained its dignity in the forest of Hainault for many centuries, and though it has very materially suffered, still maintains a majestic appearance peculiar to itself. About a yard from the ground where its rough fluted stem is thirty-six feet in circumference, it divides into eleven vast arms, not in the horizontal manner of the oak, but rather in that of the beech. The fair held beneath its shade, which overpreads an area of 300 feet in circuit, has been injurious to the parent stem, by means of fires which the visitors have occasionally kindled in the cavities formed by the decayed roots of the tree. Mr. Forsyth's composition, however, has in some degree remedied the decay; and a close fence five feet high, with a board on which is painted, "All good foresters are requested not to hurt this old tree, a plaster having been lately applied to his wounds," will, it is hoped, preserve *Fairlop oak* from further destruction.

BARKÖW, a town of Poland, in the palatinate of Braclaw; 48 miles W. N. W. from Braclaw.

BARKU, a village of Africa, in the country of Agonna, where the Dutch have a fort. See AGONNA. *Little Barku* lies about a league and a half from the former.

BARKWAY, a populous and flourishing village of Hertfordshire, in England, is situated in the hundred of Edwintree, 3 miles from Roylton, 19 from Cambridge, and 34 north from London. This is a considerable thoroughfare in the road to Lynn, and has several good inns. At the time of the conquest, the lands here were divided between four great lords into as many manors.

Barkway was anciently a market town, privileged by Edw. I. to keep a market on Tuesday, and an annual fair for six days. The market was altered in the reign of Elizabeth to Friday, and at last discontinued on account of its proximity to Roylton. The church is a handsome spacious building, and the vicarage is in the gift of the Chester family; within the building are several fine monuments and some curious painted glass. This village was greatly damaged by fire in 1748. Its houses amount to 147, and its inhabitants to 699.

BARLAAM, in *Biography*, a learned monk of St. Basil, flourished in the fourteenth century, and was born at Seminara in Calabria. Having in his youth visited Greece for the purpose of learning the Greek language, he settled at Constantinople in 1327, where he obtained by his extensive erudition the favour of the emperor Andronicus the younger, and also that of his confidential domestic John Cantacuzene, in whose house he resided. He was employed in teaching the languages and belles lettres; and in 1331, was made abbot of the monastery of the Holy Ghost. Barlaam is described by Petrarch and Boccace as a man of a diminutive stature, though eminent for his learning and genius; of a piercing discernment, though of a slow and painful elocution.

eloquence. Having visited the monks of mount Athos, he engaged with them in a controversy concerning the place of the soul and the effluence of God. These fanatical ascetics, in their mental aberrations, pretended to see the light of mount Thabor, which had been manifested to the disciples in the transfiguration of Christ, on the mountain of the navel, conceived by them to be the seat of the soul; and this light was adored by them as the pure and perfect effluence of God himself. Nor were these fanatical monks inquisitive, how the divine effluence could be perceived by the eyes of the body. Basiliana, a bold heretic, and accused them of heresy and blasphemy. His attack produced the more learned of the monks to renounce, or diminish the simple devotion of their brethren; and Gregory Palamas, who took a lead in this dispute on the part of the monks, introduced a scholastic distinction between the essence and operation of God. This distinction, however, did not escape the reproach of polytheism; and Basilian charged the adherents of Palamas with holding two eternal substances, a visible and an invisible God. The dispute was violent, and Barlaam's life was in danger. However he secured himself by a timely retreat; and Andronicus, who, with a view of obtaining the aid of the western princes against the Turks, wished to reconcile the Greek church with the see of Rome, sent Barlaam in 1339 to conduct this negotiation at the court of pope Benedict XII. at Avignon. Here he formed an intimate connection with Petrarch, whom he instructed in the Greek language; and Barlaam is said to have been the first who revived, beyond the Alps, the memory, or at least the writings of Homer. Being compelled, however, to relinquish a fruitless embassy, he returned to Constantinople, and his dispute with the monks of Athos was renewed; and the censure of a council, held in 1341, obliged him to quit the east. After a separation of three years, he renewed his acquaintance with Petrarch in the court of Naples; and by his recommendation Barlaam was finally settled in a small bishopric of his native Calabria at Hieracium, now Gerace, where he died about the year 1348. He deservedly incurred the charge of inconsistency in religion; because, when he was a Greek monk, he wrote against the Latin communion, which he vindicated after having been made a Latin bishop. Having adopted the sentiments and precepts of the stoics with respect to the obligations of morality and the duties of life, he digested them into a work intitled "Ethica ex Stoicis." He also wrote a work on arithmetic, and some letters and orations. Moreri. Gibbon's Hist. vol. xi. p. 388. vol. xii. p. 66. 120. Mosheim's Eccl. Hist. vol. iii. p. 305. 368.

BARLAAMITES, in *Church History*, the followers of the Calabrian monk mentioned in the preceding article. They are the same with those otherwise denominated *Ain-dynites*.

BARLÆUS, GASPAR, in *Biography*, an eminent Latin poet of the 16th century, was born at Antwerp in 1584, and educated for the ministry at Leyden, where he afterwards settled in the exercise of his profession, and also as sub-principal and professor of logic. But in consequence of having joined the Arminian party, he was deprived of all his employments, and devoted himself to the study of medicine, for which purpose he took a doctor's degree at Caen. In the practice of physic he made no great progress; but resuming the office of a teacher, delivered lectures in philosophy and the belles lettres to young persons at Leyden. From hence he was invited in 1631 to be professor of philosophy in the public school founded at Amsterdam, where, on account of his attachment to Arminian principles, he was the object of jealousy to the orthodox, by whom he was un-

kindly treated, and unjustly charged with Socinianism. At length he fell into the hypochondriacal maladies incident to literary men, and died in 1648. Barlaeus was a man of erudition as well as genius; and he principally distinguished himself by his Latin poetry, in which he has been thought to rival the ancients, and at least to be upon a par with Claudian. His "Poems," printed at Leyden in 1628 and 1631, contain three books of heroic pieces, two of elegies, and one of miscellanies, consisting of fables, epigrams, &c. His Latin harangues, on various subjects, were admired. Every great event that occurred called forth his exertions; and he celebrated most of the great men of his age. His "Relation of the Tractions in Brazil under the government of count Maurice" was published in 1647; and his "Letters" were collected after his death, and printed in two volumes. He also published several controversial pieces against the adherents of Arminius. Gen. Diet.

BARLAËUS, *London*, the brother of the preceding, was born at Louvain in Guelderland in 1595, and became professor of Greek in the university of Leyden. His inaugural oration "De Græcorum Literarum Præstantia ac Utilitate" was pronounced in 1641. In 1652, he published the "Timon of Lucian," with notes; and after his death, which happened in 1655, his "Commentary upon the Theogony of Hesiod" was printed in 1658. Gen. Diet.

BARLAIMONT, or BARLIMONT, in *Geography*, a town of the Netherlands, in the county of Hainaut; 4 leagues south-east of Le Quesnoy.

BARLAND, ADRIAN, in *Biography*, a writer of the sixteenth century, was born about the year 1488 at Barland, a village of Zealand, whence he took his name. Having studied at Ghent and Louvain, he became first a private teacher at the latter place, and afterwards professor of eloquence in the university; in which station he continued till his death in 1642. His works, which were all written in Latin, were numerous. Some of the principal are "Notes on Terence, Virgil, Menander, and Pliny the younger;" "An Abridgment of Universal History, from the birth of Christ to 1532;" "On the Doges of Venice;" "Chronicle of the Dukes of Brabant;" "History of the Counts of Holland;" "Life of Charles, Duke of Burgundy;" "Catalogue of the chief Towns of Lower Germany;" "De literariis Urbis Romæ Principibus." Several of his historical works were published together at Cologne, in 1603, 8vo. Moreri.

BARLENGA, in *Geography*, a small island, is the principal of a cluster in the Atlantic ocean, about 3 leagues from the west coast of Portugal, with a fort. These islands are called "Borling," by the English seamen, and most of them are merely rocks. N. lat. 39° 23'. W. long. 8° 41'.

BARLERIA, in *Botany*, a genus of plants intermediate between *Ruellia* and *Jussiaea*, named by Plumier in honour of James Barrelier, a Parisian physician and botanist. Lin. g. 785. Schreb. 1051. Plum. 31. Juss. 103. Gærtn. t. 54. Class, *dicynomia* or *gynæcia*. Nat. Ord. *Personate*—*scantli* Juss. Gen. Char. Cal. perianth four-parted, permanent: two opposite leaflets larger. Cor. monopetalous, funnel-form, quinquefid, subequal, the fifth division deeper than the others. Stam. filaments four, filiform, two very short, capillary; anthers oblong, two lower withered. Pist. germ ovate; style filiform, the length of the stamens; stigma bifid. Per. capsule acute, flat-quadrangular, two-celled, two-valved, gaping distally at the claws; partition contrary. Seeds two, compressed, roundish.

Ess. Gen. Char. Cal. four-parted. Stam. two far less than the others. Caps. quadrangular, bilocular; bivalvular, elastic without the claws. Seeds two.

Species,

Species, 1. *B. longifolia*. Anclufa. Pluk. Alm. 30. t. 133. f. 4. Morr. 3. f. 11. t. 27. f. 5. "Spines of the whorls six-fold; leaf cordiform, very long, scabrous." The stem is erect, rough, obtusely quadrangular; leaves opposite, lanceolate-sword-shaped, entire, three the length of the internodes; flowers in whorls, axillary; three spines on each side of the stem of the length of the whorl. A native of the East Indies. Introduced here by Sir J. Banks in 1781. 2. *B. filanifolia*. Plum. g. 31. 43. f. 2. "Spines axillary; leaves lanceolate, tooth-letted." Stems erect, square, three feet high, with two oblong entire leaves at every joint, above which the flowers stand in whorls, surrounding the stalks, and under each whorl are six sharp spines as long as the calyx; the flowers are blue, and more completely lobed than the other species of the genus. 3. *B. Hystrix*, hyltrix frutex. Rumph. 7. 22. 13. "Spines axillary, twin, simple; leaves entire, lanceolate-ovate." Stem wand-like, not firm; branches scarcely angular; leaves smooth on both sides; axillary spines twin, simple, sessile, horizontal. A native of the East Indies. 4. *B. Dionidia*. Colletta-Yeetla. Rheed. Mal. 9. 77. 41. "Spines axillary, pedate, fourfold; leaves entire, lanceolate-ovate." Stem herbaceous, round, stiff; leaves opposite, running down the petioles, pubescent underneath; between the branch and leaf a spine, with four sharp rays from the centre; calyxes acuminate-spiny. A native of the East Indies. 5. *B. buxifolia*. Caratchulli. Rheed. Mal. 2. 91. 47. "Spines axillary, opposite, solitary; leaves roundish, entire." Stalks shrubby, five or six feet high, with strong spines under the leaves; flowers in whorls towards the upper part of the stalk; seed-vessels short, containing three or four flat seeds. A native of Jamaica and the East Indies. 6. *B. nodiflora*. "Spines axillary, branching; leaves lanceolate, entire, cuspidated; bractes ovate, scarious; tube elongated." Flowers blue, resembling those of *B. buxifolia*, but longer, and expanding during the night; bractes smooth. Observed near Tanjour by Koenig. 7. *B. cristata*. Melampyro cognata, &c. Morr. Hist. 3. 429. f. 11. t. 23. f. 7. "Leaves oblong, entire; two leaflets of the calyx broader, ciliate, and two linear, acute." Stem round; leaves oblong-ovate, sharp at both ends, flowers axillary, sessile; two leaflets of the calyx ovate, acuminate, serrate-spiny; two alternate, shorter, linear, acute, entire, spreading; corolla blue, with ovate lobes. 8. *B. cocinea*. Plum. g. 31. 43. f. 1. "Unarmed; leaves ovate, tooth-letted, petioled." Stems smooth, four feet high; flowers scarlet, in whorls at the joints, and appearing from July till September. A native of South America. 9. *B. pungens*. "Unarmed; leaves ovate, acute, pungent; bractes ciliate." Found at the cape of Good Hope by Thunberg. 10. *B. longiflora*. Gærtn. Fruct. 253. "Unarmed; leaves ovate, silky; bractes cordate, scarious; corollas very long." An undershrub, with opposite silky branches; leaves opposite, entire, on stalks; flowers terminal; bractes two or bivalve, sessile, nearly as large as the leaves, and below these four other bractes disposed cross-wise, linear, spreading, silky, as long as the leaves; capsule pointed at each end, quadrangular; seeds much flattened, covered with wavy bundles of appressed hairs. Found on the mountain of St. Thomas in Malabar by Koenig. 11. *B. procumbens*. Lour. Cochinch. 377. "Unarmed; leaves lanceolate, crenate, hispid; heads terminal." This is a procumbent twilled rough undershrub; leaves opposite, broad-lanceolate; flowers yellow; bractes acuminate, ciliate; segments of the calyx subulate, hairy; capsule oblong, angular, with orbicular seeds. A native of China, near Canton.

Propagation and Culture. All the species of this genus require the protection of a bark-stove. The second, fourth, fifth, and eighth were cultivated by Miller, but the others

have not yet been introduced here. The second is to be propagated by seeds, which will sow themselves in the pots which are near them in the stove, when the plants are once obtained; but where the seeds are received from abroad, they must be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, plunged into a hot-bed of tanners' bark, where they must constantly remain, and be managed in the same manner as other tender exotics from the same countries; giving them water frequently in summer, and allowing them fresh air every day in warm weather. They flower from June till November. The fourth has flexible perennial stalks, which, if cut off during the summer months and made into lengths of six or eight inches, and planted in pots, plunging them into hot-beds, and duly watered and shaded from the sun, will soon put forth roots, when they may be each planted in a small pot and plunged into the tan-bed in the stove, where they are found to grow better than in the dry stove. This species rarely produces flowers in England. The fifth and eighth sorts will produce seeds which are to be treated in the same manner as the former. See Martyr's Miller's Dict.

BARLETTA, in *Geography*, a sea-port town of Italy, in the kingdom of Naples and country of Bari, on the Adriatic, 4 miles west of Trani. The inside of this city is magnificently built, though it has from without a ruinous aspect, and is thinly peopled. Frequent changes of masters, bad administration, and decay of commerce, have blatted its prosperity. Its streets are wide and well paved, and its houses large and lofty. The style of building fixes their date at the first emergence of the arts out of the chaos of barbarism; many of the houses still retaining pointed arches, short twisted columns, and other remains of Saracenic taste; while others are decorated with pillars, entablatures, and members characteristic of the ancient Grecian architecture. The city owes its embellishments to the policy of the Arragonian kings, who resided here to secure the allegiance of the Pugliese. In the cathedral, which is remarkable for its antique granite columns, Ferdinand I. was crowned. In the market-place stands a colossal bronze statue, seventeen feet three inches high, representing, as it is supposed, the emperor Heraclius, who began his reign in 1610. The citadel is spacious, and commands the port, consisting of several irregular piers, but without any shelter from the north wind, which sweeps the whole basin. The exports from this place are salt, corn, almonds, and liquorice, which latter grows spontaneously in the swamps. During the hot months the air is accounted unwholesome. Barletta is said to have derived its name from a tower, or drinking-house, situate on the road to Cannæ, having for its sign a barrel, "barilletta;" and when the cities of Cannæ and Canosa fell to decay, and the advantages of trade drew people to the coast, a numerous colony gathered round this tower, and in 484, pope Gelasius consecrated a church for the settlers, which became the cathedral of the united sees of Nazareth, Cannæ, and Monteverde. The emperor Frederick added greatly to Barletta, and has been by some called its founder. Others suppose it to have been the Barduli of the Itineraries. In the fifteenth century, Barletta was esteemed one of the four strongest fortresses in Italy; the other three being Fabriano in the Marca, Prato in Tuscany, and Crema in Lombardy. Swinb. Trav. vol. i. p. 275. N. lat. 41° 30'. E. long. 16° 32'.

BARLEY, in *Botany*, a gramineous, frumentaceous herb, whose seeds are of the larger sort, being covered with a husk, growing in a spike, and the grains bearded. See HORDEUM.

Pearl BARLEY, and **French BARLEY**, are barley freed from the husk, and rounded by a mill; the distinction between the two being, that the pearl barley is reduced to the size of small shot, all but the very heart of the grain being ground away. In mills appropriate to this purpose, the mill-stone is rough-hewn round its circumference; and instead of an under stone, has below it a wooden case, in which it revolves, and which, on the inside, is lined with a plate of iron pierced like a grater, with holes having their sharp edges turned upwards. The barley is thrown upon the stone, which, as it runs round, draws it in, frees it from the husk, and rounds it; after which, it is put into sieves, and sifted. The first kind of barley-mills is a German invention. In Holland, the first was erected at Saardam, not earlier than the year 1660. This mill, which was at first called the *Pellikam*, scarcely produced in several years profit sufficient to maintain a family; but in the beginning of the last century, there were at Saardam fifty barrel-mills, which brought considerable profit to their proprietors.

BARLEY, in *Agriculture*, a well-known kind of grain from which malt is made. Miller enumerates four different sorts of this useful grain: *spring barley*, *long-eared barley*, *sprat-barley*, and *winter barley*.

The *spring barley* has a double row of beards or awns standing erect. This is the sort principally cultivated in the southern and eastern districts of both England and Scotland, and which the farmers distinguish into two different kinds, the *common* and the *early-ripe* barley; but the two sorts are in reality the same, as the *early-ripe* is only an alteration of the *common* barley, occasioned by being long cultivated upon warm gravelly soils. The seed of this, when sown on cold or strong land, will, the first year, ripen nearly a fortnight earlier than that taken from strong land, and therefore the farmers in the low districts generally purchase their seed barley from the warm or gravelly lands; for when cultivated in the vales two or three years, it becomes full as late in ripening as the *common* barley of their own produce: on the other hand, the farmers on warm gravelly lands are obliged to procure their seed barley from the strong lands, otherwise their grain would degenerate in bulk or fulness, which by this change is prevented. This sort of barley is easily distinguished as above, and besides the rind is much thinner, and of course it is esteemed better for making malt.

The *long-eared barley* is likewise cultivated in many parts of England, and is a good sort; but some cultivators object to it, because from the ears being long and heavy they think it more apt to lodge. In this sort of barley, the grains are regularly ranged in a double row, lying over each other, like the tiles of a house, or the scales of fish. It has no beards or awns; and its rind is very thin, and therefore it is esteemed for making malt.

The *sprat-barley*, which is sometimes also called *Bath-dore*, *Fulham*, and *Putney* barley, from great quantities being cultivated in the neighbourhoods of those places, has shorter and broader ears than either of the former sorts; the awns or beards are longer, which tend greatly to preserve it from the birds, and the grains are placed together. It seldom, however, grows so tall as the other kinds; the straw is generally coarser, and therefore not so good as fodder for cattle.

The *winter barley*, which is called also *square barley*, *low barley*, and *lig*, is seldom cultivated in the southern parts of England; but in the northern counties, and in Scotland, it is the sort generally sown, as being much harder than the others. There are two kinds of this barley, the one with four rows of grains, and the other with six, the latter of

which is commonly distinguished by the name of *barley lig*. The grain is large and plump; but the rind and chaff of it being thicker than that of either of the preceding sorts, it is less esteemed for making malt.

Barley, from its being that sort of grain which is considered next in value to wheat, is very generally cultivated. On dry, light, mellow soils, the thinnest-riended and large-bodied barley, which is always esteemed the best in quality, is produced. Even light poor soils, when dry, and from nature and situation warm, yield barley which is superior in quality to that which is commonly reaped from the strongest land when cold or of a moist nature.

In the corrected report of Middlesex it is observed, that the tender nature of this plant, in its infant state, unfits it for cold and compact soils. It thrives best in a soil that is moderately dry and light, as a loamy sand, and is esteemed rather a clean crop. As, for this crop, the soil is generally well tilled late in the spring, it reduces the weeds very much; and from its occupying the ground only four months, they have not time to recover themselves and perfect their seed. This grain may and frequently is, the writer says, sown after every kind of crop, but always succeeds best after turnips, pease, beans, or others of an ameliorating quality.

In the preparation for this grain, the soil should invariably be well pulverized and rendered light first by a thin ploughing and then by harrowing, which should be followed at as great a distance as the season will admit by a more deep cross ploughing, harrowing, and rolling. The seed should then be ploughed in with a very small furrow, and immediately afterwards clover seed harrowed in with short-tined harrows, which leaves the land as light as possible. The next thing to be done is, with one horse to draw a very light roll over the land, in order to press the mould gently on the seeds. These operations promote a more certain, speedy and equal vegetation than can be procured by harrowing in the seed. Harrowing in the seed is, however, the more usual method, and is, he thinks, the cause of much grain being lost, and also of the crop being often of two or three growths. Many farmers postpone the last rolling until the first leaves of the seeds are up, but it is believed, more from the hurry of the season than from choice. This perfect tillage seldom fails to secure a good crop of barley, and a plant of clover.

In the event of hard-frosts, or excessive rains, it may be advisable not to plough the land flat, but into ridgelets of about eighteen inches wide. These will drain themselves dry in any weather, at least so much so, that two or three dry days will prepare the soil for harrowing previous to the second ploughing; and if the season should still continue favourable, the land on such second ploughing might be laid up in a similar manner till sowing-time; when two or three days more of fine weather would render it fit to be harrowed or scuffed down, and for ploughing in the seed; otherwise a third ploughing may be given, and the seed be harrowed in; which last is considered the better practice, where the soil is not quite so dry as could be wished. Scuffing the land, instead of the second ploughing, would in fine seasons dispatch the work, and be a saving of expence. In the cleanest soil it would be equal to cross ploughing, and in soils not quite free from root-weeds it would be much more useful by bringing them within reach of the harrows. It will perform more than double the quantity of work with the same number of men and horses, and leave the land equally ready for the harrow and roller before sowing the seed.

The author of the *Synopsis of Husbandry* observes, how-

ever, that it is improper to sow clover among barley on rich land, because the natural fertility of the soil hastens on the vegetation of the grass, which will before harvest have advanced to a considerable height among the corn, and will occasion a longer time to be necessary for drying the swath; and thus, by lying abroad longer than would otherwise have been required, a total destruction of the crop may ensue; but in those lands, where there is not the danger of so luxuriant an increase, clover, trefoil, and other grass-seeds may, he thinks, often be sown among barley; and if a favourable time can be procured for harrowing it, the straw may be greatly improved by the mixture of the clover or other grasses, and become then a valuable fodder in the winter; but barley-straw simply is, he says, the most ordinary cattle-food of any.

Where barley succeeds turnips, the land is sometimes only once ploughed; but the author of modern agriculture says that it is a much better method to plough it twice, first early in the spring, and again before sowing the seed. This last is the practice in Norfolk, where that species of grain is cultivated in a more perfect manner and to a greater extent after turnips, than perhaps in any other district. But when barley is sown after pease, beans, or oats, the land is commonly first ploughed in autumn; and the attentive farmer always takes care on this occasion to plough in such a manner as to expose as great an extent of surface to the influence of the air and frost as possible, and at the same time to form the ridges in such a way as to prevent the field from receiving any damage from excessive rains during winter. The second ploughing is given immediately after the oat-feeding is finished. This ploughing is intended to answer two purposes; in the first place, to loosen the couch-grass and other root-weeds where they abound, so that they may be easily taken out by the harrows, which are immediately afterwards applied; and in the second place, to reduce the soil to a finer tilth, whereby the seed-weeds are encouraged to vegetate, and which the subsequent ploughing and harrowing at seed-time effectually destroy.

This sort of grain is also frequently sown after wheat, when the same mode of culture as just mentioned is adopted. But however common this rotation of cropping may be in some districts, there is no good reason, he says, why it should be recommended to the general notice of farmers. For two white corn crops succeeding each other is undoubtedly an erroneous method, both for profit and improvement. Besides, it mostly happens, that where barley succeeds wheat, the crop is in some measure blighted, many of the stalks becoming white about the month of July; and where there are any grains in the ears, they are shrivelled and never come to maturity, though the soil may be well suited to the production of this sort of grain.

The author of the Survey of Middlesex indeed thinks, from the nature of corn crops, that barley ought not on any account to be sown after either wheat, rye, or oats; a much better practice being to sow it after turnips, potatoes, carrots, tares, &c. and in some cases, after hemp, flax, and rape. The land should not receive any further manure than what was laid on for the preceding crop, together with the dung and urine deposited by cattle during the time they are eating the green crops off the lands.

The seed season for barley begins, in most of the southern counties, about the first week of March, and terminates in the more northern ones, towards the middle of June. But from the middle of March to the end of April may be reckoned the chief barley seed season, as within these periods by much the greatest proportion of that species of grain is put into the ground.

The writer just mentioned observes, that barley, though usually sown during the months of March, April, and May, has succeeded when put in the first week in June; but it ought to be sown as early as the soil is sufficiently dry and in condition to receive it, and the prior attention which is due to the oat, tare, and other crops will permit. Let it always be kept in mind, says he, that barley will bear late sowing much better than those crops. Both the four and six-rowed kinds of barley are frequently sown in the autumn nearly at the same time with wheat, not only in temperate climates, but also in very cold countries; their hardiness being such as to bear the severity of the winter season even in the mountainous parts of the northern countries. In hot countries they are mostly sown in January, February, and March.

All the other sorts are sown in the spring of the year in a dry time, as has been already seen; when this sort of grain is sown late on strong clayey soils, if the season does not prove very favourable, it is very late in autumn before it is fit to reap or mow, unless it be the early or rath-ripe sort, which is often ripe in nine weeks from the time of sowing.

In the seventh volume of the Annals of Agriculture, Mr. Young gives the following experiments by Mr. Macro, on early and late sowing of barley; on Nov. 16, 1785, he began his experiments by sowing two bushels of barley, which he harrowed in on clover land that had been folded the same as for wheat; this first sowing, therefore, had only one earth. The barley came up about a week sooner than the wheat by the side of it, which was sown the same day, and was exceedingly flourishing till the first sharp frost set in, which damaged the blade, but did not seem to affect the root. As near the middle of December as the weather would permit, he sowed two bushels more, on exactly the same quantity of ground, and some about the middle of every month, till the month of May 1786. This and every sowing after, it had two earths; one cast, or half the seed, was ploughed in, and the other half harrowed in; all the land was folded alike in the month of November. The second sharp frost killed some of this sowing, and a good deal of that sown in November; but they both, with that sown in January, seemed to suffer still more by the sharp cutting winds in the month of March, when there was no snow to cover the blade, and it was injured by the frost. The sowings in February and March lost few, if any, of their plants, and, what was somewhat remarkable, were both forward enough to be harvested on the same day with the three preceding sowings. That sown in April was full a fortnight later; and that sown in May, there not being any so late sown in the neighbourhood, was entirely destroyed by vermin.

As he some years before intended trying the same experiment, but was disappointed of knowing the event by the stupidity of his workmen, he determined this time to prevent any mistakes by mixing the different parcels in the barn, to thresh enough of the different sowings in the field to satisfy himself which was the most profitable crop, and accordingly attended the thresher the whole day himself. As it was not at all necessary for the experiment to thresh the whole crop, he took three swaths of each sowing twelve yards in length, on the lowest part of the land, where he thought the soil was the most equal for the purpose of the experiment, which, he should have observed before, were by the side of each other on the same piece of land. He had every parcel dressed and put into a sack by itself as soon as threshed, and the account stood thus:

From

	Pecks.	Qrs. P.	Pints.	Combs.	Bushels.	Pecks.	Qts.
From that sown in November 72 sq. yards.	3			12	2	1	
December		3	1	12	3	1 $\frac{1}{2}$	1 $\frac{1}{2}$
January	3	1		13			
February	2	3	2	11	2	2 $\frac{1}{2}$	
March	2	2	2	10	3	3 $\frac{3}{4}$	1
April	2		2	8	3	2 $\frac{1}{4}$	1
May	0	0	0	0	0	0	0

The last sowing, as observed above, was entirely destroyed by the rooks; he believes it had not been sown more than three days before they began to scrape and pick it up, and completely devoured it. It was the same with the very early sowings, but that he expected, and was guarded against. It may however serve he thinks, as a lesson to young farmers, that although early sowing may in most cases be profitable, yet it will not answer in large open fields, where the lands are intermixed, unless neighbours sow at the same time; for, if only one farmer sows early, he must have as many keepers as he has pieces of land. The barley of all the sowings was of the Zealand stock. On the same piece of land on which he tried the above experiments, which was a deep sand, value about six or seven shillings per acre, he tried two others, one about ten years since, with chalk from different pits, some of which was a dry chalk, and others greasy; he carried only one load of each sort, and laid it about the thickness of seventy loads to an acre. Neither of them did the least good, for he could not tell by any of the crops since, without looking at the soil, where they were laid. The other was by deep ploughing, in the autumn of 1785, when he sowed part of the piece with wheat, by going with a second plough after the first for one stretch only, and raising about three or four inches of soil that had never been turned up before; on viewing it about midsummer he could not find where it was by any apparent difference in the crop, nor could he see that the barley sown in January was the best crop. By the same rule, when he began to try the experiment before, that sown in February was the best, and it appeared so on view, he remembers, all the summer.

The quantity of seed barley allowed to the acre varies very much; and depends not only on the quality of the land and the season, but on what was the preceding crop, and also on the condition of the land for receiving the seed. When barley succeeds turnips, the land being then in the best state for the seed, a less quantity is necessary than if it were to be sown after two or three successive white corn crops. The usual allowance to the acre is from three bushels and a half to five; but four bushels and a peck may be considered as the general average, so large a quantity as five bushels being never sown but on lands exhausted and worn out by improper cropping.

Mr. Middleton remarks (in his Survey of Middlesex) that early sowing requires less seed than late; but on a medium soil in proper condition, sown broad-cast, in March three and a half, in April four, and in May four and a half bushels per acre are sufficient. A rich soil makes such a great difference, that it can hardly be sown too thin; even one bushel and a half early sown, has produced as much as could stand; whereas had three or four bushels been sown, the crop would have been lodged, and of a very reduced value.

It is observed by Mr. Donaldson, that if a statement of

the average returns of barley by the acre was confined to England and the south of Scotland, it might be rated at thirty-two bushels; but when Wales and the north of Scotland are included, where, owing to the imperfect modes of culture still practised, the crops are very indifferent, the general average over the whole will not probably exceed twenty-eight bushels the acre. The author of the Agricultural Report of Middlesex states it as varying in England from fifteen to seventy-five bushels per acre. The average produce of the county of Middlesex, he says, is about four quarters of corn and two loads of straw per acre. The straw usually sells at about a guinea a load delivered in, which, with chaff and thin grain, is equal to one shilling and sixpence per bushel on the corn; and as the corn has averaged three shillings, together they produce four shillings and sixpence per bushel, or seven pounds four shillings per acre.

The ultimate destination of barley to be converted into beer and spirits, he says, raises the value of this crop to more money per acre than that of any other grain. For after the farmer has disposed of it, the maltster, brewer, distiller, rectifier, and victualler, successively draw the wages of labour and profit from it before it comes to the consumer. Including a revenue of five millions and one quarter a year, which it nets to government, but which costs the subject between six and seven millions, its entire expence to the consumer at this time is not less than thirty pounds an acre. He understands that porter is brewed in the ratio of 162 gallons from one quarter of malt; and is sold by the retailer after the rate of one shilling and two-pence per gallon, which produces nine pounds nine shillings; deduct the value of the hops, and there remains upwards of a guinea a bushel for the malt, or full thirty pounds an acre. In the article of spirits, he thinks, it must necessarily yield much more. According to Mr. Donaldson, barley is applied to various uses. In Wales, Westmoreland, Cumberland, and in the north, as well as in several parts of the west of Scotland, the bread used by the great body of the inhabitants is made chiefly from barley. Large quantities of the barley cultivated in England are converted into beer, ale, porter, and what is called British spirits, as English gin, English brandy, &c. The remainder, beyond what is necessary for feed, is made into meal, and partly consumed in bread by the inhabitants of the above districts, and partly employed for the purpose of fattening black-cattle, hogs, and poultry. There is a much greater share of the Scotch barley consumed in distillation in proportion to the quantity cultivated, than there is in England. Exclusive of what is used for feed, the Scotch barley is either converted into beer or ale; or made into pot barley, or into meal, for the use of the inhabitants in the more remote and less cultivated parts of the kingdom; or, lastly, into whiskey.

In the Report of Middlesex it is also stated, that much of the most ordinary barley is given to poultry; the rest is sold to the maltsters, except so much as is reserved for feed.

In respect to pearl barley it is observed, that a mill to manufacture it costs about twenty pounds. A ton, or 160 stone, of pearl barley sells for twenty three pounds, which is rather under three shillings a stone, or thirteen shillings and four-pence a bushel. Twenty-three stone and a half of common barley produces five stone and a half of pearl barley by the common method of manufacturing it; but by an addition to the mill, which would only cost two pounds, the barley corn would be split, and then the same quantity would yield nine stone of pearl barley. This is stated on

the authority of evidence before a committee of the London Society of Arts.

With regard to the choice of seed barley, it is necessary to observe that the best grain for sowing is that which is free from blackness at the tail, and is of a pale lively yellow colour, intermixed with a bright white ear; and if the tail be a little shrivelled, it is so much the better, as it shows that it has sweated in the mow, and is a true indication that its coat is thin. The husk of thick-rinded barley being too stiff to shrink, will be smooth and hollow even when the inside flour has shrunk from it.

The necessity of a change of seed from time to time, by sowing that of the growth of a different soil, as has been observed, is in no instance more evident than in the culture of this grain, which otherwise becomes coarser and coarser every year. But in this, as well as in all other grain, the utmost care should be taken that the seed be full bodied.

It is easy to suppose that barley, like wheat, may be benefited by being steeped before it is sown. For as rain cannot always be depended upon soon after the sowing of spring corn, there is surely an equal reason for extending the practice to these sorts of grain as well as those which are sown in autumn. Liming indeed may hurt barley in some cases, but a little sprinkling of foot bids fair for improving it, at least it may prevent insects from preying upon the seed.

Mr. Middleton indeed remarks, that the seed is never steeped, and yet the farmers are continually complaining of its coming up at different periods, thus producing two crops which do not become ripe at the same time, and are injurious to the sown. Steeping the seed a proper number of hours, which might be ascertained by experiment, seems (he says) to be as well calculated to secure a uniform vegetation and prevent this complaint, as poisoning the seed appears to be to keep it from vermin.

According to Miller, the common method is to sow the barley-seed with a broad-cast at two sowings; the first being harrowed in at once, but the second not until the seed is buried. The common allowance of seed is four bushels to an acre: but (says he) if the farmers could be prevailed upon to alter this practice, they would soon find their account in it; for if a third part of that quantity be sown, there will be a much greater produce, and the corn will be much less liable to lodge, as he has many times experienced; for when corn or any other vegetable stands very close, the stalks are drawn up weak, and thence incapable of resisting the force of the winds, or supporting themselves under heavy rains; but when they are at a proper distance, their stalks will be more than twice the size of the other, and therefore are seldom laid. He says he has frequently observed in fields where there has been a foot-path through their middle, that the corn which has stood thin on each side of the path has stood upright, when all the rest on both sides has been laid flat on the ground; and whoever will give himself the trouble to examine these roots near the path, will find them tiller out, that is, have a greater number of stalks, to more than four times the quantity of the other parts of the field. He has seen experiments made by sowing barley in rows across divers parts of the same field, and the grains sown thin in the rows, so that the roots were three or four inches asunder in the rows, and the rows a foot distant; the intermediate spaces of the same field were at the same time sown broad-cast in the usual way. The success was this: the roots which stood thin in the rows, tillered out from ten or twelve to upwards of thirty stalks on each root; the stalks were stronger, the ears longer, and the grains larger, than any of those sown in the common way; and when those parts of the field where the corn was

sown in the usual way have been lodged, these parts sown thin have supported their upright position against wind and rain, though the rows have been made not only length-ways but across the lands in several positions, so that there could be no alteration in regard to the goodness of the land, or the situation of the corn. When therefore such experiments have been made, and always attended with equal success, there can be no room to doubt which of the two methods is most eligible, if the crops were only supposed to be equal. But the sowing two thirds of the corn sown is a very great advantage, and deserves a rational consideration, as such a saving in scarce times might be of very great benefit to the public. This sowing of seed-corn (says he) must be understood to regard such as is sown broad-cast; for if it be sown in drills, an eighth part of the seed usually sown will be sufficient for an acre of land, and the produce be greater; for all sorts of corn are naturally inclined to send out several stalks from each root, which they rarely fail to do where the roots are at a proper distance and have room; nor do the stalks grow in this case near so tall, but are much stronger than when they are near together, when they rarely have more than two or three stalks, whereas those roots which have proper room seldom have less than ten or twelve. He has had eighty stalks upon one root of barley, which were strong, produced long ears, and the grain was better filled than any he ever saw grow in the common method of husbandry, and the land on which this grew was not very rich; but he has frequently observed on the sides of hot-beds in the kitchen gardens, where barley straw has been used for covering the beds, that some of the grains left in the ears have dropped out and grown, the roots have produced from thirty to sixty stalks each, and those have been four or five times larger in size than the stalks ever arrive at in the common way. But to this, he knows, it may be objected, that although upon rich ground in a garden these roots of corn may probably have so many stalks, yet in poor land they will not have such produce; therefore, unless a greater quantity of seeds be sown, the crop will not be worth standing; which is (he says) one of the greatest fallacies that can be imagined; for to suppose that poor land can nourish more than twice the number of roots in the same space as rich land, is such an absurdity as one could hardly suppose any person of common understanding guilty of: and yet so it is; for the general practice is to allow a greater quantity of seed to poor land than for richer ground; not considering that where the roots stand so close, they will deprive each other of their nourishment, and consequently starve themselves, as is always the case when the roots stand close, which any person may at first sight observe in any part of the fields where the corn happens to scatter when they are sowing it; or in places where by harrowing the seed is drawn in heaps, those patches will starve, and never grow to a third part of the size as the other parts of the same field; and yet, common as this is, it is little noticed by farmers, otherwise (says he) they surely would not continue their old custom of sowing. He has made many experiments for several years in the poorest land, and has always found that all crops which were sown or planted at a greater distance than usual, have succeeded best upon such land; and he is convinced, if farmers would be prevailed upon to quit their prejudices and make trial of the method of sowing their corn thin, they would soon see the advantage of this husbandry.

The experiments of Mr. Young, however, lead us to a different conclusion. On April 25th, 1791, upon a land of moist loam on a wet marl bottom, worth about sixteen shillings an acre, he marked four beds, each eight feet long

long by three feet broad, and dibbled them with four-rowed barley.

- No. 1, 91 holes, and four seeds in each hole.
 2, 198 ditto, three seeds in each.
 3, 198 ditto, one seed in each.
 4, 198 ditto, two seeds in each.

No hoeing given; but before they ripened a net was suspended over the whole, to guard the barley from the ravages of birds.

On Sept. 5th he reaped them, and clipping off the ears, weighed them.

- No. 1, 28½ ounces.
 2, 31.
 3, 20½.
 4, 24.

- In No. 1, 13 grains of seed give one ounce produce.
 2, 19 grains of seed, one ounce produce.
 3, 9¾ ditto, ditto.
 4, 16½ ditto, ditto.

- In No. 1, 18 grains of seed per square foot.
 2, 24 ditto, ditto.
 3, 8 ditto, ditto.
 4, 16 ditto, ditto.

It seems (says he) remarkable, that comparing No. 1 and 4, the seed are nearly the same, yet the crop is different, and very considerably in favour of the seed being crowded together in clusters, rather than spread much more equally over the ground. This (continues he) is a most singular circumstance; it coincides very much with the modern practice of dibbling wheat, which has been changed gradually from one grain in a hole, to two, three, and even four, and this cluster-sowing has been found to answer best. But upon what principles? and owing to what cause? Theory would seem to tell us, that plants standing single would have regular spaces for the roots to feed in, without struggling with each other for nourishment; but there must be some other circumstance which more than balances this advantage. The farmers say that the plants assist each other: but how? Is it by shelter? is it by an accelerated fermentative motion from additional warmth? Very obscure all this, but highly deserving further repeated and varied experiments. Mere quantity of seed appears to have much effect; No. 2, the most seed, has of all the greatest crop.

It is a common practice in some parts, to scatter the dung of pigeons, poultry, &c. over barley and other grain after they are sown; but if this method be pursued, care should be taken to scatter such dungs on immediately, because then the shoot will easily make its way through; but when laid on later, it is apt to burn up and destroy the blades of the young plants.

It often happens, on the more stiff soils, from unfavourable weather and an extremely dry spring, that it is impossible, by the common method, to break the clods and prepare the ground sufficiently for sowing barley; in which case it has been the usual method to break the clods with a large beetle, called from its use a *clotting-beetle*: but this being a very expensive and tedious method of preparing land, induced the ingenious Mr. Randall of York to construct an instrument, which he calls a *spiky roller*, by the assistance of which a large quantity of land may, in such a dry season, be soon reduced to an exceeding fine tilth, with very little trouble. See SPIKE ROLLER.

After the barley is sown and harrowed in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth, which will render it easier to mow the crop, and also cause the earth to lie closer to the

roots of the corn, which may be of great service to it in dry weather: and also when the barley has been up three weeks or a month, it may be a good method sometimes to roll it over with a weighty roller, which will again press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground in dry seasons; and this rolling of it before it stalks, may likewise cause it to tiller out into a greater number of stalks; so that if the plants should be thin, it may cause them to spread so as to fill the ground, and likewise strengthen the stem.

If the corn should grow too rank, as is sometimes the case in a wet spring, mowing is then much better than feeding it, because the scythe takes off only the rank tops, but the sheep feed upon all indifferently; nor should they even in any case be left upon it too long, because, being particularly fond of the sweet end of the stalk next the root, they bite so closely as to injure the future growth of the plant.

Barley is ripe when the *red roan*, as the farmers term it (a reddish colour on the ear), is gone off, or when the ears droop and fall as it were double against the straw, and the stalks have lost their verdure. If it be full of weeds, it must lie in the swath till they are dry. It is not apt to shed, but in wet weather it will be apt to sprout or grow mussy; and, therefore, every fair day after rain it should be shook up and turned; and when it is tolerably dry, let it be made up into sheaves: but be careful never to house it till thoroughly dry, lest it mow-burn, which will make it malt worse than if it had sired in the field.

BARLEY, *Causitic Indian*. See VERBASCUM *Sevadilla*.

BARLEY Water (*Decoction Hordei P. Lond. & Ed.*). It is of some consequence that the preparations which generally fall under the care of the nurse, should be made with as much attention as those of the apothecary. Barley water, either by itself or with a variety of additions, forms an agreeable and valuable drink for the sick room. When prepared in the following manner, it is smooth, uniform, and palatable. Take of pearl-barley two ounces, water five pounds: first wash the barley from the mealy matter that adheres to it, with some cold water; then boil it a little with about half a pound of water to extract the colouring matter; throw this away, and put the barley thus purified into five pounds of boiling water, which is to be boiled down to one half, and strained.

Barly Water Compound. (*Decoction Hordei Compositum P. Lond.*) Take of the preceding barley water two pints; sliced figs two ounces; liquorice root, sliced and bruised, half an ounce; raisins, stoned, two ounces; water one pint; boil to two pints, and strain. This decoction is more tasteful than the former, and is very palatable; it forms a good demulcent liquor in sore throats of every kind, and is very considerably nourishing. It is apt, however, to cloy the stomach if taken in large quantity; lemon juice, or any other acid, may be added to it with advantage.

BARLEY-bird, in *Ornithology*, a name given in Suffex to the *Siskin*.

BARLEY-corn is used to denote a long measure, containing in length the third part of an inch, and in breadth the eighth.

The French carpenters also use barley-corn, *grain d'orge*, as equivalent to the line or the twelfth part of an inch.

BARLEY-corn, *grain d'orge*, is also used, in *Building*, for a little cavity between the mouldings of joiners' work, serving to separate or keep them asunder; thus called because made with a kind of plane of the same name.

BARLEY-sugar. See SUGAR.

BARLEY-cove, in *Geography*, a creek on the south-west coast

coast of Ireland, between Mizen-head, the *Noium* of Ptolemy, and Browhead in the county of Cork. N. lat. $51^{\circ} 24'$. W. long. $9^{\circ} 40'$.

BARLOWE, WILLIAM, in *Biography*, was a descendant of the ancient family of the Barlows in Wales, and born in the county of Essex. He was at first a monk in the Augustine monastery of St. Osith in Essex; and having commenced his education in this place he finished it at Oxford, where he obtained the degree of doctor in divinity. He afterwards became prior of the canons of his order at Bisham in Berkshire, and at the dissolution of the monasteries he resigned his house, and prevailed on many abbots and priors to follow his example. In 1535 he was appointed bishop of St. Asaph, and in 1536 translated to St. David's, where he formed the unsuccessful project of removing the episcopal see to Caermarthen, as being situated more in the centre of the diocese. He was a favourite of king Henry VIII., and was employed by him in the matter of his divorce; and he was also much esteemed by lady Ann Boleyn. In 1547, he was translated to Bath and Wells; but as he was attached to the protestant religion, he was deprived of his bishoprick in 1553, upon queen Mary's accession, on pretence of his being married, and committed to the Fleet prison. Having made his escape from confinement, he retired with many others to Germany; where he remained in a poor and distressed condition till the happy inauguration of queen Elizabeth. On this occasion he returned to his native country, and in 1559 was promoted to the see of Chichester, where he died in 1568. He was reckoned a learned prelate; but appears, notwithstanding his profession of the protestant religion, not to have possessed the spirit of a martyr. Besides other pieces which he wrote, he was concerned in the compilation of the treatise entitled "The Godly and Pious Institution of a Christian Man," commonly called the "Bishop's Book," printed at London in 1537; and in the reign of Edward VI. he is said to have translated into English the "Apocrypha" as far as the book of Wisdom. He had five daughters, all of whom were married to bishops. *Biog. Brit.*

BARLOWE, WILLIAM, son of the former, was born in Pembrokehire, and in 1560 entered at Baliol college. He afterwards travelled, and became skilful in navigation. On his return he took orders in 1573, and obtained several preferments in the church, the last of which was that of the archdeaconry of Salisbury, to which he was promoted in 1614. He died at Easton near Winchester in 1625. In his acquaintance with the nature and properties of the loadstone, he seems to have preceded Dr. William Gilbert, and wrote upon this subject twenty years before Gilbert's book was published. He was the first that made the inclinatory instrument transparent, and to be used hanging with a glass on both sides and a ring at the top; and he also contrived to hang it in a compass box, and to adapt it for use at sea. He was also the first person that discovered the difference between iron and steel, and their respective tempers, for magnetical purposes. He also shewed the right method of touching magnetical needles, and shewed how to piece and cement load-stones. Moreover he explained the reason why a load-stone being double capped, takes up so great a weight. On these subjects he wrote the following books, viz. "The Navigator's Supply, &c." 4to. Lond. 1597; "Magnetical Advertisements, &c." 4to. Lond. 1616; and "An Answer to Dr. Ridley's Animadversions on this work." *Biog. Brit.*

BARLOW, THOMAS, a learned English bishop of the 17th century, was born at Langhill in the parish of Orton in Westmoreland in 1607, and educated at Queen's

college in Oxford. In 1635, he was appointed reader of metaphysics in the university, and his lectures were published. On the surrender of Oxford to the parliament in 1646, he retained his fellowship, and in 1652 was appointed keeper of the Bodleian library. In 1657, he was chosen provost of his college. Upon the restoration he contrived to be chosen one of the commissioners for restoring the members that had been wrongfully ejected in 1648, and in 1660 was created doctor of divinity and Margaret professor in that department. In this year he wrote "The Case of a Toleration in Matters of Religion," which he extended farther than any divines of that age. As he was distinguished for his skill in the civil and canon law, he was often applied to as a counsel; and in 1671, he wrote Mr. "Cottington's Case of Divorce." In 1675, he was promoted, notwithstanding the opposition of archbishop Sheldon, to the bishoprick of Lincoln; and after his advancement wrote several pieces particularly against popery, which served to found the alarm with respect to the danger of a popish successor. However on the accession of James II., he was one of the most forward in procuring thanks to the king for his declaration in favour of liberty of conscience, and he vindicated the regal power of dispensing with penal laws; which conduct some have censured as manifesting an unwarrantable accommodation to the times, and others have ascribed to his love of toleration. With the revolution he adopted its principles, and avowed his allegiance to the successors of James. As to his sentiments, he was in theology a rigid Calvinist; and in philosophy a strict Aristotelian, and an enemy to the new mode of experiment encouraged by the Royal Society. As a bishop he neglected his duties in his cathedral and diocese, and resided constantly at his manor seat at Bugden; nevertheless his tolerating spirit and opposition to popery seem to have produced in the author of the "Confessional" a singular predilection in his favour. He died at Bugden in 1691, in the 84th year of his age; and he was eminently distinguished by his learning and liberality. The works of this bishop, printed after his death, were a volume of "Cases of Conscience," resolved by him, 8vo. 1692; and his "Genuine Remains," 8vo. 1639. *Biog. Brit.*

BARLOW, FRANCIS, a painter of birds, beast, and fish, was born in Lincolnshire, and excelled in drawing every species of animals with great correctness; but his knowledge of colouring was very imperfect. This artist died in 1702. *Pilkington.*

BARM, otherwise called yeast; the head or workings producing by the fermentation of ale or beer. It is the froth that forms on the surface of beer or wine of grains during their fermentation; which, mixing with dough, raises it more quickly and better than leaven, and makes the lightest bread. See LEAVEN, and YEAST.

BARMACH, in *Geography*, a lofty mountain of Persia, in the province of Schirvan near the Caspian sea.

BARMANCOTTY, a town of Acha, in the country of Thibet, five miles south of Sirinagur, and thirteen north of Deuprag.

BARMEA, *Havn*, is a large bay, situated about four miles S.W. by W. from cape Machicao, two leagues N.E. by N. from Placencia, and four from Bilbao.

BARMEN, a town of Germany, in the circle of Westphalia and duchy of Berg, situate in a fertile valley to which it gives name, five miles north of Lannep.

BARMINE denotes such mine or ore as is adjudged at a court of barghnote.

BARMOUTH, in *Geography*, is a small watering place in the parish of Llanaber, Merionethshire, North Wales. The houses

houses are singularly placed at the bottom and on the side of a steep hill which overlooks a narrow winding valley to the south, and the bay with St. George's channel on the west. The situation of the houses affords matter of astonishment to most travellers; some being placed on the sands close to the beach, and others at such varied heights on the rocks, that in some of the winding paths a person may look into the door of one house on his right hand, and down the chimney of another on his left. This place is at the mouth of the river Mawddach, which at high tide forms a bay of about one mile over; but the entrance is rather unsafe on account of the sand banks. The Welsh call it Aber-maw, i. e. the mouth or confluence of the river Maw. Barmouth is much frequented as a convenient bathing place during the summer by many gentry families. Here are a few bathing machines for the use of ladies, but the gentlemen commonly bathe from the coast. This place is the port of Merino fishery, and great quantities of flannels and hose are annually exported hence. Mr. Pennant states that forty thousand pounds' worth of the former and ten thousand pounds' worth of the latter have been shipped from this port in one year. About one hundred vessels belong to this place, some of which sail up the river nearly to Dolgelly.

Not far from Barmouth, the river Mawddach divides into two arms, and forms a small island called Ynys y Brawd, or the friar's island. The number of houses in this parish is 317, and its inhabitants amount to 1463. Bingley's Tour round North Wales.

BARN, in *Rural Economy*, a covered building constructed for the purpose of laying up and preserving all sorts of grain, hay, straw, &c. Arable as well as hay farms should in general be provided with barns proportioned to the quantity of grain or hay they produce; though since the practice of stacking hay and grain and of threshing by mills has become more general, there seems to be much less need of large barns.

Buildings of this sort should have a dry, rather elevated situation; and be placed on the north or north-east side of the farm yard, but not by any means contiguous to the house or such offices as are connected with it.

Barns may either be constructed on wooden frames and covered on the outsides with weather boarding, or built of brick or stone, which ever the country affords in the greatest plenty; but in either case, there should be such vent-holes or openings in their sides or walls as may be sufficient to afford free admission to the air, in order to prevent the mouldiness that would otherwise from the least damp lodge in the grain. The gable ends of such buildings are probably always best formed of brick or stone, on account of their greater solidity; the whole may be roofed with either thatch or tiles as can be most conveniently procured. They should have two large folding doors facing each other, one on each side of the building, for the convenience of carrying in or out a cart or waggon load of corn in sheaves or any other sort of bulky produce: and these doors should be of the same breadth with the threshing floor, to afford the more light and air; the former for the threshers, and the latter for the purpose of winnowing the grain. Over the threshing floor, and a little above the reach of the flail, poles are often laid across from one beam to another, to form a kind of upper floor, upon which the thresher may throw the straw or haulm, to make an immediate clearing till he has time to stow it properly elsewhere; and on the outside over the great doors, it is sometimes convenient to have a large pent house, made to project sufficiently to cover a load of corn or hay, in case a sudden storm should come on before it can be

housed, and also to shelter the poultry in the farm yard from too great heat or bad weather of any kind.

It was formerly much the custom in countries that abounded in corn to have separate barns for wheat, for spring-corn, such as barley and oats, and for peas, tares, clover, saintfoins, &c. but where the grain, hay, and other similar produce can be stacked, the heavy expence of so many buildings of this kind may be avoided, and at the same time the different articles be preserved with equal safety and convenience. In the corn barns it was formerly also much the custom to have bays or large separate chambers formed in their sides or ends for the purpose of containing the grain when threshed out, straw, and other articles; but these at present are not so much in use. The hay barns should constantly be constructed of wood and not made too close. They are sometimes formed in such a manner as to be capable of being moved to different places by having low wheels or rollers fixed on the bottom frame. In grazing farms that do not afford a supply of straw for thatching the stacks with, moveable roofs erected on strong upright poles of wood, or what are sometimes termed Dutch barns, may be useful; as they may be raised or lowered at pleasure by screws or levers so as to accommodate themselves to the quantity of hay, either in proportion to the crop or its consumption; while at the same time they are cheaper, more airy, and less troublesome in case of heating, than close barns.

It is observed in the sixteenth volume of the *Annals of Agriculture*, in speaking of the construction of barns, that the underpinning should be of brick or stone, two feet high above ground, and the sides boarded; the roof of the barn is best covered with reed or straw, and those of the stables on its sides with slate or glazed tile; because they must be more flat, and the water which runs from the roof of the barn would injure most other coverings. At each end of the barn, and over the back door, small doors four feet square should be fixed at the height of twelve feet from the ground; the two former for putting corn in at the ends, and the latter for filling the middle of the barn after the bays are full. All the bays should have a floor of clay or marl, and the threshing floor be made with hard bricks, which will be sufficient for all sorts of grain except wheat and rye; and for threshing them it will be good economy to have planks of oak or red deal well fitted together and numbered, to be laid down occasionally and confined by a frame at their ends. A barn built on such a plan would hold a great deal of corn and be filled most conveniently; and if the stacks of corn were built at each end, they might be taken in without any carting. If more buildings are requisite, two may be added on the back side like the stables in front; otherwise if doors are made under the eaves on the back side, as directed at the ends, and stacks be placed opposite to them just far enough to avoid the eaves' dropping, by placing a waggon between them and the barn by way of a stage, these stacks may be taken in without carting; which method spares a great waste of corn and much trouble. The spars of the roofs of the stables rest upon the upper eills of the sides of the barn, and the outside wall of the stables is eight feet high; the barn supplying the highest side and one end of each stable, and the stables in return are buttresses to the barn and strengthen it greatly.

It is remarked by the author of the *Agricultural Survey* of the county of Somerset, that the practice lately introduced of placing barns on a declivity cannot be too much recommended; as a warm commodious range of stalls for cattle, covered by the same roof, is by that means obtained.

Belles,

Besides, the barn-floor, by being thus elevated, is rendered more durable, and less subject to vermin; the grain is kept more dry and sweet than on a ground floor, and cannot slip through it without discovery. The plan is indeed, in his opinion, almost unexceptionable. Barns, when built in this way, should have a southern aspect, the arches of the cattle-stalls facing that way. Mr. Marshall, in the "Rural Economy of Yorkshire," also speaks highly of the advantages of barns formed in this manner.

In respect to the size of barns, the same writer has observed, that in Gloucestershire fifty-two by twenty feet in the clear, and from sixteen to twenty feet in height to the plate, is considered a good barn: these dimensions admitting of four bays of ten feet each, with a floor in the middle.

The advantage of having buildings of this sort conveniently situated, is extremely great both in regard to the feeding of cattle, sheep, and hogs, and likewise in the economy of labour, and the preventing of waste in different kinds of fodder.

The invention of threshing machines has, in some measure, varied the construction of barns, as where they are made use of they should be contrived chiefly with a view to the distribution of the straw; the machines being built in the centre, with the grain stacks adjoining them, in such a manner as that they may be supplied without the assistance of carts or horses. The barns in these cases need not be so large, but they should have granaries provided in them, which may probably be most conveniently placed over the floors. In most old barns, threshing machines may be erected without much inconvenience or trouble.

But, notwithstanding the superiority of stacking grain in the open air has been fully shewn by different writers, and of course the necessity of large barns in a great measure obviated, there are still many agriculturists attached to the method of housing corn in the straw; it may therefore be proper to give a few plans and descriptions of such as appear to be the best calculated for that purpose.

At *fig. 1. Plate I. of Agriculture*, are given the elevation and ground plan of a small common barn used in most parts of the kingdom for the smaller kinds of farms. The threshing-floor is in the middle; on one side of which a cross wall is sometimes raised to the height of about three feet, in order to keep the threshed corn from being mixed with that which is unthreshed: *e* is a place for containing the threshed grain till it be cleaned, or a large quantity be accumulated for that purpose. It is about three feet in height, being covered over with boards, and only open on the side next the threshing-floor of the barn.

At *fig. 2*, the elevation and ground plan of a double barn with two threshing floors are seen. In this sort of barn a wall is sometimes raised across in the middle. These barns are often built of large dimensions, but possess few conveniences, except for piling up the grain while in the straw.

At *fig. 3*, the elevation and ground plan of an improved barn are given, in the middle of which is the threshing floor, and on one side near the end a place for depositing the threshed corn, with stairs up to a small granary, below which is a place for putting potatoes, &c.; and on the other a division that may be made use of for different purposes, such as the rearing of calves, preserving implements, &c.

And at *fig. 4*, the elevation and ground plan of an open improved barn are shown, the threshing floor of which is placed towards one end. And on each side of it below are divisions for a great variety of different purposes; the corn being kept above in the straw till threshed out. In this

barn much expence is saved in masonry by the great number and largeness of the openings in the upper part, and at the same time the air is admitted more freely.

Fig. 5 is the representation of a Dutch moveable barn which has many conveniences, and at the same time is capable of being made to cover the parts of such hay stacks as are cutting. It moves on six wheels each two feet in diameter, and costs, when complete, about sixty pounds.

Some degree of art, which must be the result of practice, is necessary in placing and piling up the sheaves in barns; and it may not be useless to observe, that it is always necessary to press them as close to the walls of the barn as possible, so as not to afford the least room for rats or other vermin to creep in between them, for if they once get admittance, they will soon penetrate farther, lodge themselves in the mow, and do prodigious damage to the grain. Where this misfortune happens, the only remedy is to take down the mow, destroy the vermin, and pile it up anew in a more careful manner.

As the introduction of threshing machines has made considerable alteration in the construction of barns, it may not be improper to give a few plans or representations by which the manner of their attachment to them may be rendered more clear and comprehensible. These machines may be wrought by different powers, as water, wind, or animals; but the first, when it can be obtained, is by much the best and most regular.

At *fig. 1. Plate II. of Agriculture*, are given a front and end elevation, with the plan, of a small barn adapted for a two-horse threshing machine. The barn is only fifty feet in length within the walls, and sixteen in width. The walls are ten feet in height, which admits of a granary or room thirty feet long above the machine, as is shown by the dotted line in the elevation, which denotes the extent of the granary as well as the height of the floor from the ground. The floor is not continued the whole length, in order that there may be more room left in the other end for containing the unthreshed grain, which is introduced at *a*, *figs. 2* and *3*. At *b*, *fig. 2*, is seen the space occupied by the machine within the barn, which is only ten feet by seven, including the distance from the wall; *c*, *d*, *figs. 2*, and *3*, shew the horse beam or lever; which is twenty four feet in length, and which gives motion by a laying shaft through the wall, to the machine within. In this there is no shed or cover over the horse path and parts on the outside of the barn, as is usual, except *g*, *b*, *fig. 2*, which is closely boarded to protect the wheels of the first movement from the effects of weather, a part of one side being fixed with hinges for the purpose of opening to apply grease. The expence of a machine on this plan will be from thirty to forty pounds, according to the strength and manner of its being put together.

And at *fig. 4*, are seen the front and end elevations, with the plan, of a barn and horse threshing machine upon a much larger scale, being intended for three or four horses or other sorts of cattle; and designed to winnow or clear the grain at the same time that it is threshed out. It may likewise be so contrived as to hoist it up to the granary above, to split beans, cut straw, and perform several other operations, such as churning, pumping, grinding, &c. Such a barn and machine will suit a farm of almost any extent. The shed over the horse-path and first movements is mostly made with a conical roof merely for the purpose of covering them; but as the expence is considerable, it is here made to answer other uses. It is square, as shewn at *fig. 5*, by *a*, *b*, *c*, *d*; the dotted circle is the horse-path, in the corner of which stands the upright axle *e*, *fig. 6*. Above this, by raising the pillars to a proper height, may be obtained a convenient place

place either for putting corn in the straw till threshed out, or for keeping straw or hay, or as a granary. But in either case the floor must be so constructed as to support the weight upon it without sinking in the middle. A communication with the barn may be made near the threshing machine at *f*, *fig. 5*, which will afford an easy access to the machine in case grain be deposited there to be threshed. In this barn, the machine is erected on a floor raised seven or eight feet above the ground-floor, in order that there may be sufficient room for the farmer or winnowing machine below. This floor may be extended the whole breadth of the barn and fifteen feet or more towards *i*, from the back part of the machine at *f*, by which, and being properly partitioned below, a very necessary and useful division *f*, *k*, *i*, will be obtained for containing the grain till hoisted up to the granary. The doors of this place may be locked by the farmer, if thought necessary, during the time of threshing. The space *k* will contain the chaff blown by the fan. There is a door through at *g* to render the communication more easy and expeditious from the part *i*, where the unthreshed grain is deposited; as it may be proper to look often below while the machine is at work: there might likewise be a door in the partition at *b*; but this is not so very necessary, as the farmer can easily see what his servants are about at *m* where the straw goes, by standing on the threshing floor, to which there should be steps up at *n*. This machine may also be so constructed as to rake away the straw, and throw it down to *m*; which saves the labour of a person in raking from the machine.

The expence of a machine on this plan, when made to clean the grain and rake away the straw only, will amount to about fifty pounds exclusive of flooring, &c.; and when made so as to hoist up the grain, split peas or beans, and cut straw, from six to ten pounds in addition for each.

Other more powerful machines of this kind will be described under the article *THRESHING Machine*.

BARN Floor, in *Rural Economy*, the space or floor on which the grain is threshed out by the flail. It is for the most part made in the middle of the barn, and should be so formed as to be perfectly close, firm, and strong. It is sometimes termed threshing-floor. In constructing these floors, various sorts of materials are employed; such as compositions of earthy kinds, stones, bricks, and wood. The last, when properly laid and put together, is probably the best and most secure from such causes as are liable to injure grain. The floors of barns, when made of wood, are sometimes so contrived as to be moveable at pleasure, which is a great convenience in many cases. Barn floors are made of different dimensions, but from twelve to fourteen by eighteen or twenty feet may be considered as good sizes.

As the floor, or threshing-place, is the principal part of every barn, the greatest care ought to be taken in making it. In order to this, in some places the surface of the intended threshing-place is dug away to the depth of about six inches; and the earth thus taken out, when of a proper kind, after being well cleared of stones, is mixed with the strongest clay that can be procured, and with the dung of cattle. This mixture is then worked together with water till it is of the consistence of stiff mortar, and the compost thus made is spread as smooth and even as possible with a trowel upon the spot from whence the earth was taken. As it cracks in drying, it must frequently be beaten down with great force, or rolled with a heavy roller, until all the crevices are filled up; and this must be continued till it is quite solid, hard, and firm. Earthen floors are not however to be recommended, except where the materials are ex-

trinsely good, and the method of forming them well understood, which is but seldom the case.

The best barn floor, both for threshing upon and for keeping corn, is that which is the driest, smoothest, most completely solid, and consequently the most free from cracks and holes in which insects and vermin may shelter themselves and breed. The ancients were remarkably careful in this last respect, as is evident from the writings of Cato, Varro, and Columella. The last of these relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh lees of oil, but not with any that had filike matters in them; then to mix it thoroughly with chaff, and run it down as close as possible; afterwards, as it dried, to stop all the cracks and crevices that appeared; to continue beating it down with great force to render it quite level; and, lastly, to strew it again with chaff, which they trod in, and then left it to be completely dried by the sun. All of them agree, that the lees of oil thus used prevent the growth of weeds in the floors, and contribute to preserve the corn from being plundered by the mice and ants. In this they were, however, probably mistaken. Their barns were always seated high, and as dry as possible. A floor made in the above manner, though not good, was probably preferable to either stone or the earthen floors formerly common in many parts of this country, from which such dampness has been communicated to the corn, as has rendered wheat, for example, sixpence or a shilling a bushel worse either for keeping or exportation. Bricks, when hard and well laid, may form a tolerable floor for many purposes; but, from their attracting moisture, are not by any means to be recommended where grain is to remain much upon them. And most sorts of stone are liable to the same objection.

Wood is by much the best for this use. Boarded threshing floors, made of sound, thick, well-seasoned planks of oak, are excellent for threshing upon, will last a long time, and may be converted into good floorings for rooms, by planing them down after they are become too uneven for the purpose originally intended.

There are various ways of laying and constructing barn floors, when made of wood. The most common method is that of nailing the planks, after their edges have been shot true and well joined, down to wooden sleepers firmly placed on the ground. But in the midland counties another method is followed, which, Mr. Marshall says, is that of first having the floors laid with bricks, and then covering them over with the planks, without any other confinement than that of their being dowed together, or ploughed and tongued, and their ends let into fills or walls placed in the usual manner on each side of the floors. The advantages of this method of making the floors are, that when the brick work is well executed and made perfectly level, vermin cannot be concealed underneath them, nor damp air be communicated; besides, floors formed in this way are found to wear better than those laid simply upon sleepers. The planks employed in this way should, however, always be well seasoned. It is evident, notwithstanding, that where barn floors can be made hollow, they must be much better for the purpose of threshing upon than such as are either placed on brick work or the ground, from their greater elasticity; the grain is of course threshed out with more ease and certainty. But in whatever manner these floors are constructed, they become expensive, and do not last any great length of time. Such as are laid on the common ground, upon three fills, with two-inch oak planks, will in general cost from eighteen to twenty pounds, and only last fifteen or twenty years; and such as are made hollow, and placed wholly on brick work,

Besides, the barn-floor, by being thus elevated, is rendered more durable, and less subject to vermin; the grain is kept more dry and sweet than on a ground floor, and cannot slip through it without discovery. The plan is indeed, in his opinion, almost unexceptionable. Barns, when built in this way, should have a southern aspect, the arches of the cattle-stalls facing that way. Mr. Marshall, in the "Rural Economy of Yorkshire," also speaks highly of the advantages of barns formed in this manner.

In respect to the size of barns, the same writer has observed, that in Gloucestershire fifty-two by twenty feet in the clear, and from sixteen to twenty feet in height to the plate, is considered a good barn: these dimensions admitting of four bays of ten feet each, with a floor in the middle.

The advantage of having buildings of this sort conveniently situated, is extremely great both in regard to the feeding of cattle, sheep, and hogs, and likewise in the economy of labour, and the preventing of waste in different kinds of fodder.

The invention of threshing machines has, in some measure, varied the construction of barns, as where they are made use of they should be contrived chiefly with a view to the distribution of the straw; the machines being built in the centre, with the grain stacks adjoining them, in such a manner as that they may be supplied without the assistance of carts or horses. The barns in these cases need not be so large, but they should have granaries provided in them, which may probably be most conveniently placed over the floors. In most old barns, threshing machines may be erected without much inconvenience or trouble.

But, notwithstanding the superiority of stacking grain in the open air has been fully shewn by different writers, and of course the necessity of large barns in a great measure obviated, there are still many agriculturists attached to the method of hoisting corn in the straw; it may therefore be proper to give a few plans and descriptions of such as appear to be the best calculated for that purpose.

At *fig. 1. Plate I. of Agriculture*, are given the elevation and ground plan of a small common barn used in most parts of the kingdom for the smaller kinds of farms. The threshing-floor is in the middle; on one side of which a cross wall is sometimes raised to the height of about three feet, in order to keep the threshed corn from being mixed with that which is unthreshed: *c* is a place for containing the threshed grain till it be cleaned, or a large quantity be accumulated for that purpose. It is about three feet in height, being covered over with boards, and only open on the side next the threshing-floor of the barn.

At *fig. 2*, the elevation and ground plan of a double barn with two threshing floors are seen. In this sort of barn a wall is sometimes raised across in the middle. These barns are often built of large dimensions, but possess few conveniences, except for piling up the grain while in the straw.

At *fig. 3*, the elevation and ground plan of an improved barn are given, in the middle of which is the threshing floor, and on one side near the end a place for depositing the threshed corn, with stairs up to a small granary, below which is a place for putting potatoes, &c.; and on the other a division that may be made use of for different purposes, such as the rearing of calves, preserving implements, &c.

And at *fig. 4*, the elevation and ground plan of an open improved barn are shown, the threshing floor of which is placed towards one end. And on each side of it below are divisions for a great variety of different purposes; the corn being kept above in the straw till threshed out. In this

barn much expence is saved in masonry by the great number and largeness of the openings in the upper part, and at the same time the air is admitted more freely.

Fig. 5 is the representation of a Dutch moveable barn which has many conveniences, and at the same time is capable of being made to cover the parts of such hay stacks as are cutting. It moves on six wheels each two feet in diameter, and costs, when complete, about sixty pounds.

Some degree of art, which must be the result of practice, is necessary in placing and piling up the sheaves in barns; and it may not be useless to observe, that it is always necessary to press them as close to the walls of the barn as possible, so as not to afford the least room for rats or other vermin to creep in between them, for if they once get admittance, they will soon penetrate farther, lodge themselves in the mow, and do prodigious damage to the grain. Where this misfortune happens, the only remedy is to take down the mow, destroy the vermin, and pile it up anew in a more careful manner.

As the introduction of threshing machines has made considerable alteration in the construction of barns, it may not be improper to give a few plans or representations by which the manner of their attachment to them may be rendered more clear and comprehensible. These machines may be wrought by different powers, as water, wind, or animals; but the first, when it can be obtained, is by much the best and most regular.

At *fig. 1, Plate II. of Agriculture*, are given a front and end elevation, with the plan, of a small barn adapted for a two-horse threshing machine. The barn is only fifty feet in length within the walls, and sixteen in width. The walls are ten feet in height, which admits of a granary or room thirty feet long above the machine, as is shown by the dotted line in the elevation, which denotes the extent of the granary as well as the height of the floor from the ground. The floor is not continued the whole length, in order that there may be more room left in the other end for containing the unthreshed grain, which is introduced at *a*, *figs. 2* and *3*. At *b*, *fig. 2*, is seen the space occupied by the machine within the barn, which is only ten feet by seven, including the distance from the wall; *c, d*, *figs. 2*, and *3*, shew the horse beam or lever; which is twenty four feet in length, and which gives motion by a laying shaft through the wall, to the machine within. In this there is no shed or cover over the horse path and parts on the outside of the barn, as is usual, except *g, h*, *fig. 2*, which is closely boarded to protect the wheels of the first movement from the effects of weather, a part of one side being fixed with hinges for the purpose of opening to apply grease. The expence of a machine on this plan will be from thirty to forty pounds, according to the strength and manner of its being put together.

And at *fig. 4*, are seen the front and end elevations, with the plan, of a barn and horse threshing machine upon a much larger scale, being intended for three or four horses or other sorts of cattle; and designed to winnow or clear the grain at the same time that it is threshed out. It may likewise be so contrived as to hoist it up to the granary above, to split beans, cut straw, and perform several other operations, such as churning, pumping, grinding, &c. Such a barn and machine will suit a farm of almost any extent. The shed over the horse-path and first movements is mostly made with a conical roof merely for the purpose of covering them; but as the expence is considerable, it is here made to answer other uses. It is square, as shewn at *fig. 5*, by *a, b, c, d*; the dotted circle is the horse-path, in the corner of which stands the upright axle *e*, *fig. 6*. Above this, by raising the pillars to a proper height, may be obtained a convenient place

place either for putting corn in the straw till threshed out, or for keeping straw or hay, or as a granary. But in either case the floor must be so constructed as to support the weight upon it without sinking in the middle. A communication with the barn may be made near the threshing machine at *f*, *fig. 5*, which will afford an easy access to the machine in case grain be deposited there to be threshed. In this barn, the machine is erected on a floor raised seven or eight feet above the ground-floor, in order that there may be sufficient room for the fanner or winnowing machine below. This floor may be extended the whole breadth of the barn and fifteen feet or more towards *i*, from the back part of the machine at *f*, by which, and being properly partitioned below, a very necessary and useful division *f g i h*, will be obtained for containing the grain till hoisted up to the granary. The doors of this place may be locked by the farmer, if thought necessary, during the time of threshing. The space *k* will contain the chaff blown by the fanners. There is a door through at *g* to render the communication more easy and expeditious from the part *i*, where the unthreshed grain is deposited; as it may be proper to look often below while the machine is at work; there might likewise be a door in the partition at *h*; but this is not so very necessary, as the farmer can easily see what his servants are about at *m* where the straw goes, by standing on the threshing floor, to which there should be steps up at *n*. This machine may also be so constructed as to rake away the straw, and throw it down to *m*; which saves the labour of a person in raking from the machine.

The expence of a machine on this plan, when made to clean the grain and rake away the straw only, will amount to about fifty pounds exclusive of flooring, &c.; and when made so as to hoist up the grain, split peas or beans, and cut straw, from six to ten pounds in addition for each.

Other more powerful machines of this kind will be described under the article *THRESHING Machine*.

BARN Floor, in *Rural Economy*, the space or floor on which the grain is threshed out by the flail. It is for the most part made in the middle of the barn, and should be so formed as to be perfectly close, firm, and strong. It is sometimes termed *threshing-floor*. In constructing these floors, various sorts of materials are employed; such as compositions of earthy kinds, stones, bricks, and wood. The last, when properly laid and put together, is probably the best and most secure from such causes as are liable to injure grain. The floors of barns, when made of wood, are sometimes so contrived as to be moveable at pleasure, which is a great convenience in many cases. Barn floors are made of different dimensions, but from twelve to fourteen by eighteen or twenty feet may be considered as good sizes.

As the floor, or threshing-place, is the principal part of every barn, the greatest care ought to be taken in making it. In order to this, in some places the surface of the intended threshing-place is dug away to the depth of about six inches; and the earth thus taken out, when of a proper kind, after being well cleared of stones, is mixed with the strongest clay that can be procured, and with the dung of cattle. This mixture is then worked together with water till it is of the consistence of stiff mortar, and the compost thus made is spread as smooth and even as possible with a trowel upon the spot from whence the earth was taken. As it cracks in drying, it must frequently be beaten down with great force, or rolled with a heavy roller, until all the crevices are filled up; and this must be continued till it is quite solid, hard, and firm. Earthen floors are not however to be recommended, except where the materials are ex-

trremely good, and the method of forming them well understood, which is but seldom the case.

The best barn floor, both for threshing upon and for keeping corn, is that which is the driest, smoothest, most completely solid, and consequently the most free from cracks and holes in which insects and vermin may shelter themselves and breed. The ancients were remarkably careful in this last respect, as is evident from the writings of Cato, Varro, and Columella. The last of these relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh lees of oil, but not with any that had saline matters in them; then to mix it thoroughly with chaff, and ram it down as close as possible; afterwards, as it dried, to stop all the cracks and crevices that appeared; to continue beating it down with great force to render it quite level; and, lastly, to strew it again with chaff, which they trod in, and then left it to be completely dried by the sun. All of them agree, that the lees of oil thus used prevent the growth of weeds in the floors, and contribute to preserve the corn from being plundered by the mice and ants. In this they were, however, probably mistaken. Their barns were always seated high, and as dry as possible. A floor made in the above manner, though not good, was probably preferable to either stone or the earthen floors formerly common in many parts of this country, from which such dampness has been communicated to the corn, as has rendered wheat, for example, sixpence or a shilling a bushel worse either for keeping or exportation. Bricks, when hard and well laid, may form a tolerable floor for many purposes; but, from their attracting moisture, are not by any means to be recommended where grain is to remain much upon them. And most sorts of stone are liable to the same objection.

Wood is by much the best for this use. Boarded threshing floors, made of sound, thick, well-seasoned planks of oak, are excellent for threshing upon, will last a long time, and may be converted into good floorings for rooms, by planing them down after they are become too uneven for the purpose originally intended.

There are various ways of laying and constructing barn floors, when made of wood. The most common method is that of nailing the planks, after their edges have been shot true and well joined, down to wooden sleepers firmly placed on the ground. But in the midland counties another method is followed, which, Mr. Marshall says, is that of first having the floors laid with bricks, and then covering them over with the planks, without any other confinement than that of their being dowled together, or ploughed and tongued, and their ends let into sills or walls placed in the usual manner on each side of the floors. The advantages of this method of making the floors are, that when the brick work is well executed and made perfectly level, vermin cannot be concealed underneath them, nor damp air be communicated; besides, floors formed in this way are found to wear better than those laid simply upon sleepers. The planks employed in this way should, however, always be well seasoned. It is evident, notwithstanding, that where barn floors can be made hollow, they must be much better for the purpose of threshing upon than such as are either placed on brick work or the ground, from their greater elasticity; the grain is of course threshed out with more ease and certainty. But in whatever manner these floors are constructed, they become expensive, and do not last any great length of time. Such as are laid on the common ground, upon three sills, with two-inch oak planks, will in general cost from eighteen to twenty pounds, and only last fifteen or twenty years; and such as are made hollow, and placed wholly on brick work,

or only on brick quoins, with two-inch and half oak planks, are still considerably higher, being often from twenty-five to thirty-five pounds or more, and not much more durable. Beech floors, which were lately introduced instead of oak, have been found not to last more than seven or eight years; consequently to be by no means advantageous.

In order therefore to obviate the continued heavy expences of these floors, as well as the great consumption of timber in the construction of them, and also to guard against the great waste of grain in threshing upon them after they begin to decay, another kind of barn floor has been invented by Mr. Upton of Petworth in Sussex, which has been found on trial to prevent these inconveniences in a great measure, and at the same time to afford other great advantages, such as those of being more easily drawn upon by loaded waggons or carts; providing, when down, comfortable shelter for hogs; and, when turned up, being capable of being employed as a stable, ox-stall, hovel, or cart-house. This is the *moveable barn floor*, which, it is said, can be placed or displaced in a few minutes by two persons.

This new-constructed hollow floor is composed of oak planks five feet eight inches in length, and one inch and an half in thickness, and costs from twenty-three to twenty-four pounds. By these dimensions being considerably less than those used in common barn floors, much advantage is gained in respect to timber; besides, planks of deal, beech, or elm, may be made use of, as they will not be liable to decay, from there being little or no dampness, and in this way the expence be lessened: and when timber from the estate is employed, it may be still farther diminished, as these floors may be composed of stuff of small scantlings, which may be had from short timbers of but little value in comparison to those made use of in other kinds of barn floors. It is supposed that floors constructed in this method will last an hundred years, or as long as the barns; as they are perfectly free from damp, from their being so much raised from the ground when down; also from their being moveable, when there are more barns than one in the same yard, they may be conveyed from one to another, and by that means save the expence of having different floors.

At *fig. 7. Plate II. of Agriculture*, may be seen the representation of a barn floor of this kind; one part of which affords a view of the floor as laid down for threshing upon, and the other part is raised up, with racks for feeding cattle, &c.: *a* rack boards, *b* slip boards for admitting air, *c* wooden floor fills for the slip boards *l* to rest upon, *d* moveable floors, to one part of which are wooden legs serving to support it when it is necessary to put the displaced timbers into the recesses *e*; *e* a recess for receiving the threshed grain before it is winnowed, or for containing the moveable timbers; *f* an iron hook to lift the floor up with when not used for threshing upon; there are two of these hooks employed in the barn; *g* the moveable timbers that support the floor, having grooves along their surfaces to prevent the loss of grain; two of these timbers are represented larger at *gg*; one being the cross piece with a leg and tenon for fixing in the stone mortises, the other intended to lie lengthwise, and level with the floor of the barn; in the ground are fixed stones with mortises in them to receive the tenons of the timbers described above: *h* the ground, which should be made of materials sufficiently hard to prevent the horses, carts, or waggons from making depressions in it; *i* posts with iron hasps, to support the floors when out of use; *k* racks for feeding cattle at, when the barn is applied to other purposes than threshing upon. When the floor is not wanted for threshing upon, the floors may be first turned up and fixed with the iron pins, bolts, and hasps; then the middle tim-

bers be taken out and placed on the ground, on the side opposite to the recess where they were to be deposited when out of employ; afterwards that part of the floor which has legs to support it must be let down, putting the timbers into the recess, and turning the floor up again.

Though floors of this kind may be highly convenient and useful in particular instances of large barns, where much threshing by the flail is required, yet from their complexity, and their requiring much room when out of use as floors, they do not seem well calculated for those of the smaller kinds.

BARN, or *White Owl*, in *Ornithology*, is in England the common name of that species of STRIX, which is found about barns and out-houses, and which is specifically called *flammea* by Gmelin, and some other naturalists.

BARNABAS, SAINT, in *Biography*, a teacher of Christianity cotemporary with the apostles, was a Levite of the country of Cyprus. His original name seems to have been "Joseph;" and the appellation of "Barnabas," signifying "Son of Consolation or of Exhortation," was conferred upon him by the apostles. He was one of those Christians who, soon after the resurrection of Christ, sold their property and laid the money at the apostles' feet. Acts, iv. 36, 37. By him St. Paul was presented to the other apostles three years after his conversion, or about the year 37 of the vulgar æra; and he was appointed a missionary to Antioch, in order to confirm the disciples. From thence he went to meet Paul at Tarsus, and they resided together a year at Antioch; and were afterwards entrusted with the conveyance of alms to the Christian brethren at Jerusalem. A. D. 44. Here he was declared joint apostle of the Gentiles with Paul, whom he accompanied to various places and with whom he co-operated in preaching the gospel. At length a dissension occurring between them with respect to Mark, whom Paul refused to accept as a companion, they separated, probably in friendship and mutual good will, and Barnabas with Mark as his associate went to Cyprus. St. Luke bears this honourable testimony to Barnabas, that he "was a good man, and full of the Holy Ghost, and of faith." Such is the substance of the account given of him in the New Testament. Some of the ancients, however, have supposed that he was one of Christ's seventy disciples, whom he employed during his ministry as a preacher in the land of Judæa. It has been said that he suffered martyrdom, being stoned to death by the Jews of Cyprus at Salamis; that he was buried by Mark in a cave near that city, and that his body was discovered in this island in the reign of the emperor Zeno about A. D. 488, with the gospel of St. Matthew written in Greek with his own hand, upon his breast. Lardner's works, vol. ii. p. 11, &c.

BARNABAS, *Epistle of*, in *Ecclesiastical History*, an epistle still extant, ascribed to St. Barnabas. It consists of two parts; the first being an exhortation to constancy in the belief and profession of the Christian doctrine, particularly as to its simplicity without the rites of the Jewish law, and the second part containing moral instructions. Learned men have differed with regard to the genuineness of this epistle. It is cited by St. Clement of Alexandria and by Origen. Eusebius reckons it among those books that are spurious, meaning probably by the term, contradicted. St. Jerom says, that it was read for edification among the apocryphal scriptures. Amongst the moderns, Pearson, Cave, Du Pin, Wake, Dr. Clarke, and many other learned men, suppose it to be a genuine epistle of Barnabas the companion of Paul. Some are doubtful, as Cotelerius, who inclines to think that it was not written by Barnabas. The objections against the genuineness of it are strongly urged by

Bafnage,

Bafnage, and alfo by Mr. Jeremiah Jones. To this purpofe he alleges that it is not in any of the ancient catalogues of facred books; that it is not cited in fcripture by any of the fathers; that it was not read in the afsemblies of the primitive Chriftians; that it contains contradictions, notorious falfehoods, and grofs miftakes; and alfo many things that are trifling and filly.

Mofheim fays that it was the production of fome fuperftitious Jew whofe attachment to Jewifh fables, as well as mean abilities, fhew that, notwithstanding the uprightnefs of his intentions, he muft have been a very different perfon from the true Barnabas who was St. Paul's companion. Mr. Jones fupposes that it was written by a perfon who had been originally a Gentile or Pagan.

Dr. Lardner thinks it moft probable, that it was written by Barnabas, foon after the deftruction of Jerufalem by Titus, in the year of our Lord 71 or 72; and that it was addreffed not to Jews, as archbifhop Wake fupposes, but to Gentiles, or perhaps rather to Chriftians in general, and intended to abate their refpect for the peculiar rites and institutions of the Jewifh laws and to fhew that they were not binding upon Chriftians. It was written in Greek; but the four firft chapters or fections, and a part of the fifth, are wanting in the Greek copies. It is however entire in an ancient Latin verfon. This epiftle has no infcription, as it is not directed to the Chriftians of any particular place; and on this account it has been fometimes called a Catholic epiftle. Lardner's works, vol. ii. 12, &c. Jones's New and Full Method of fettling the Canonical Authority of the New Teftament, vol. ii. p. 500, &c. Mofheim's Eccl. Hift. vol. i. p. 113.

BARNABAS, ST. *Gospel of*, a fpurious gospel mentioned by pope Gelafius, in his decree againft apocryphal books. The Turks have a gospel under this name, in which there are many things injurious to Chrift and honourable to Mahomet. It was compofed in Arabic, as M. de la Crofe thinks, under the emperor Frederic II., A. D. 1211 to 1245, and was translated into Italian about the middle of the 15th century. Profeflor White has given extracts from this gospel at the end of his "Sermons at the Bampton Lectures."

BARNABAS'S, ST., *Day*, in the *Calendar*, a Chriftian feftival celebrated on the 11th of June.

BARNABAS, *Cape*, in *Geography*, lies in the north-weft of America, in N. lat. 57° 13', between Trinity ifland and Cape Greville.

BARNABE, ST., *Island*, is fituated at the mouth of a fmall river of this name which falls into the river St. Laurence, and moft remote to the north-eaft on the fouthern or ftarboard fhore in coming down from Quebec.

BARNABITES, in *Ecceftiaftical Hiftory*, an order of religious thus called from the church of St. Barnabas at Milan, where they were firft eftablifhed, and which was beftowed upon them in the year 1545; and not as fome have imagined becaufe St. Barnabas was their patron: in reality, St. Paul is the patron of the Barnabites.

The Barnabites are regular prielts of the congregation of St. Paul. Their habit is black, and the fame with what they wore when firft eftablifhed, in 1533, by the exprefs bulls of pope Clement VII. and afterwards confirmed by Paul III. Their office is to inftruct, catechize, and feive in miffion.

BARNACH, in *Geography*, a fmall ifland near the weft coaft of Ireland, fituate in Black Sod bay.

BARNACIS, in *Ancient Geography*, a town of Hifpania Tarragonenfis, in the territory of the Carpetani. Ptolemy.

BARNACLE, or BERNACLE, in *Conchology*, is the

common name of the fpecies of LEPAS called *Anatifera*; and is applied alfo in a general manner to all the fhells which belong to the LEPAS genus.

BARNACLE-GOOSE, or BERNACLE-GOOSE, in *Ornithology*, the common Englifh name of that kind of goofe which was deemed the offspring of the Lepas Anatifera in the fixteenth century. See ANATIFERA, and ANAS ERYTHROPUS, the latter being the Linnæan name of the Barnacle goofe.

BARNADESIA, in *Botany*, a fhrub fo named by Mutis, from Michael Barnades, a Spanifh botanift. Lin. g. Schreb. 1260. Supp. 55. Juff. 178. Clafs. *synzenefia polygamia equalis*. Nat. Ord. *Composita difcoidea—Corymbifera* Juff. Gen. Char. *Cal.* common, fomewhat ventricofe, fpreading at the tip, imbricate; feales numerous, gradually longer from the bafe to the tip; the inferior or exterior, ovate, clofely imbricate, fharp, pungent; the fuperior or interior, fubulate, flat, fpreading, pungent. *Cor.* compound, rayed; corollets hermaphrodite, tubular, very few (three or four), remote, in the difk ligulate, in a fimple feries, in the ray. Proper to the former, funnel-form; tube very fhort; border hairy, five-parted; parts converging. Proper to the latter, ligulate, lanceolate, fpreading at the bafe, incurved at the tip, and fplit, outwardly very hairy; tube longer than the calyx. *Stam.* filaments five; anthers cylindric, tubular. *Pist.* germ ovate; fyle filiform, longer than the ftamens; ftigma bifid; clefts fpreading, ovate-rounded. *Per.* none; calyx converging; feeds very many, ovate, hairy; hairs reverfed. Down of the flowers of the difk briftly; rays fubulate, ftiff, broken backwards, naked or covered with minute hairs; of the radial flowers long, erect, fpreading, many-rayed, feathery, foft. Recept. flat, villofe, without chaff.

Eff. Gen. Char. *Cal.* naked, imbricate, pungent. *Cor.* radiate; down of the ray feathered, of the difk briftly, broken backwards.

Species. *Barnadesia spinofa* is a fhrub with very fmooth branches, fet with a pair of thorns at their origin, which at firft were fipules; they are petalous, brown, fmooth; leaves alternate, fimple, ovate, entire, fharp, flat, veined, fomewhat hairy on both fides, whitifh underneath; petioles very fhort; fipules in pairs, fmall, fubulate; flowers in panicles, terminating; calyx pubefcent. The flower is fingular in having two forts of down. This, which is the only fpecies of this genus, is a native of South America, where it was difcovered by Mutis.

BARNARD, or BERNARD, JOHN, in *Biography*, was born at Caftor in Lincolnfhire, and educated at Queen's college in the univerfity of Cambridg. In 1648, he was admitted, by order of the vifitors appointed by parliament, fellow of Lincoln college at Oxford. After the reftoration, he conformed, and was promoted to be prebendary in the church of Lincoln. He died at Newark, on a journey to the Spa, in 1683. He was in good repute for his learning and orthodox principles, and was author of the following books; viz. "Confura Clerior, againft Scandalous Minifters, &c." 4to. 1660; "Theologe-Hiftoricus, or the Life of Dr Heylyn," whofe daughter he married, 8vo. 1683; "An Anfwer to Baxter's falfe accufation of Heylyn;" and a "Catechifm" for the ufe of his parifh. *Biog. Brit.*

BARNARD, SIR JOHN, a patriotic citizen and diftinguifhed magiftrate of London, was born at Reading in Berkhire, in 1685, of parents who were Quakers, and educated at a fchool belonging to perfons of this perfuafion at Wandiworth in Surry. In early life he was diftinguifhed by the integrity and candour of his mind, fo that all differences among his fchool-fellows were fubmitted to his decifion. In the fixteenth year of his age, his father, who was now fettled in

London in the wine-trade, introduced him into his own business; and his conduct was such as fully to justify the confidence that was reposed in him. Amidst other avocations that occupied his thoughts and time, he directed his particular attention to religion; and without doubt from conviction, renounced the profession of his parents, and became a proselyte to the established church. Accordingly he was baptized by Dr. Compton, bishop of London, after several previous conferences, at his chapel in Fulham, in 1703. It was the uniform practice of Mr. Barnard, from his earliest youth, to associate with persons of riper age than his own, and with such as were distinguished by their talents, learning, and religion; and his improvement in knowledge and virtue corresponded to the selection he made of his companions and friends. In this course of sedulous application to mental culture as well as to secular employment, Mr. Barnard persevered till he had attained the thirty-sixth year of his age; and he was only known in private life by the excellencies of his character. About this time a bill that materially affected the wine-trade had passed the commons, and was depending in the upper house. The merchants that were likely to be injured by the operation of this bill, appointed Mr. Barnard to state their objections before the lords; and such were the abilities which he manifested on this occasion, and such was the success that attended his exertions, that in 1721 he was proposed, without his knowledge, as a candidate to represent the city of London at the next election, which took place in the following year. The contest was as warm as any that had ever been known in the city; but Mr. Barnard, though he declined all personal solicitation, succeeded by the zeal and activity of his friends. His parliamentary conduct, during a period of forty years, was in the highest degree independent and respectable; and he derived from his character as well as talents singular influence. He distinguished himself by his opposition to the measures of administration, then conducted by sir Robert Walpole, and particularly to the extension of the excise, which he condemned both in a commercial and political light, and which, by his vigorous and assiduous efforts, he induced the minister at length to abandon. Heedless of popularity in measures which in his judgment concerned the good of his country, he attempted to reduce the interest of the national debt from four to three per cent.; and by his endeavour incurred a temporary odium. In 1732 he had obtained the honour of knighthood, on occasion of presenting a congratulatory address to king George II.; and in 1737 he was raised to the dignity of the chief magistrate of the city of London; an office which he executed with singular reputation to himself and advantage to the public. So attentive was he to the duties of this office, that he would not sleep a single night in his house at Clapham, lest any person should be injured by his temporary absence. No magistrate was ever more vigilant in his attention to the internal police of the city over which he presided; and blended lenity with severity in the administration of it with so much discretion. He would never suffer any person to be committed to prison for a single night, till the accusation against him had been fairly heard; for he well knew the danger to which unguarded youth would be exposed even by a short abode in these receptacles of infamy. The state of our gaols had been the object of his particular investigation, and he was fully apprized of those abuses that needed correction and restraint. In 1745 sir John Barnard took the lead in signing an agreement to take bank notes in lieu of cash, and in thus supporting public credit at a period of peculiar danger. In 1749, he became the father of the city; and the London merchants

had previously, viz. in 1747 testified their veneration of him by erecting his statue in the Royal Exchange. This token of respect, however, he disapproved; as he thought that no character was entitled to it, till its perseverance in integrity had been sealed by death: and such was his modesty, that he never after transacted business within this edifice. In 1754 he was for the last time, without solicitation and in opposition to his own wishes, elected a representative of the city; but his infirmities increasing, he thought proper, in 1758, to resign his alderman's gown. After some years of honourable retirement, he died at Clapham in 1764, leaving one son (distinguished by his taste in the polite arts, and by his admirable collection of pictures) and two daughters. Few persons ever sustained a character so uniformly respectable as sir John Barnard. He was not only blameless, but eminently exemplary in the various relations and offices of life. To the faithful and active discharge of the personal and social duties, he added a most devout sense of religion. The first hour, at least, of every day was employed in the exercise of devotion and the study of the scriptures. He attended public worship twice on a Sunday, and was constant in receiving the communion. He had such a high reverence for the bible, that he always expressed a great dislike of any attacks which were made upon its sacred original and authority. Although he relinquished the profession of his youth, he retained, in a considerable degree, that simplicity of manners and plainness of dress which distinguish the respectable body to which his family belonged. But though he was modest in his deportment, he was firm and fearless in the discharge of his duty. His language was clear, concise, and unaffected; and his wisdom and knowledge were recognized by persons of the first character in his time; inasmuch that he was urged in 1746, by king George the second, to accept the office of chancellor of the Exchequer, which he refused. Lord Granville and Mr. Pulteney frequently consulted him on affairs of moment; and lord Chatham, when Mr. Pitt, has been known to stile him the great commoner. The muse of Pope, by exhibiting him in contrast to worthless wealth and title, has immortalized his name.

“Barnard in spirit, sense, and truth abounds;

Pray then what wants he? Four-score thousand pounds.”

Biog. Brit.

BARNARD, in *Geography*, a township of America, in Windsor county and state of Vermont, containing 673 inhabitants. It gives rise to the northern branch of Water-queche river, and is distant 65 miles N. E. from Bennington.

BARNARD CASTLE, or **CASTLE BERNARD**, a town of Durham, in England, 246 miles N. N. W. from London, and 26 from Durham. The town is about a mile in length, and consists of several streets; the principal of which is upwards of forty yards in width, and is mostly filled with handsome modern buildings. The air of this part of the country is remarkably salubrious, the market is abundantly supplied, and the situation possesses every advantage to render it pleasant. The woollen manufactory has declined of late from the great use of cotton goods; much business is done by the tanners; and the stocking trade is particularly flourishing. This town is mentioned as existing soon after the conquest; though it was then probably but an insignificant place, as it derived its chief consequence as well as its name from the magnificent castle founded here by Bernard Baliol about the year 1178. This fortress is situated on the summit of a high rock to the westward of the town, and was anciently of much importance; maintaining a number of officers, and being vested with high privileges

leges by its different possessors. We find the names of John Baliol father to the king of Scotland, the celebrated Guy Beauchamp earl of Warwick, and Richard duke of Gloucester afterwards Richard III., occur among the proprietors of the castle. The latter founded a college for a dean, 12 secular priests, 10 clerks, and 6 choristers; but it is presumed that his intentions were in part frustrated by the subsequent troubles of his reign, as no traces of this foundation are now discernible. In the reign of Charles I., this castle, after being several years in the possession of the crown, was purchased by an ancestor of the present earl of Darlington, and gives a title to his lordship's eldest son. In the year 1699 it was created a barony by king William III. The present remains cover about six acres of ground. The parts of chief strength stand on the brink of a steep rock about eighty perpendicular feet above the river Tees, and every way command a most beautiful prospect. Many fragments of the ruins have the arms of Richard the third, who is supposed to have considerably contributed to this building. Though we can readily ascertain from the above that this fortress must have been a place of great strength and extent, yet it is not possible to form any competent idea what it was in its original and perfect state. Leland in particular mentions parts of which there are not the least remains. The environs of the town are remarkably beautiful; the vale of the Tees abounding with a great variety of picturesque, pastoral, and august scenery. From the castle cliffs northward, the river is bordered by a hanging forest of oaks on one hand, and on the other by fine meadow land. The extended battlements, the circular tower and the most stately parts mantled with ivy, the brown rocks fringed with brush wood, the brighter yellow towers, and the dark and shaded battlements, are contrasted by the azure lake on whose surface they are reflected. Near the path on the margin of the river is a fine new bridge of one arch, lately erected by Saurey Morrit Esq. of Rokeby Park. The number of houses in the township is 312, and its inhabitants 2966. Hutchinso's History of Durham, vol. iii. 4to.

BARNARDO ISLANDS, are five islands on the north coast of South America, laid down in modern charts off the north point of the entrance into Morosquillo bay. They lie S. S. W. from the harbour of Cartagena, in the direction of the coast. To the west of south from them is the opening into the gulf of Darien, which is the limit between North and South America. These islands form a large bay and harbour in N. lat. $9^{\circ} 35'$ and W. long. $77^{\circ} 20'$. The outermost island is called St. George's, the innermost is St. Gilbertus, and Goerce island lies between them. The river Chenu is to the west of these islands.

BARNASNE, mountains of Ireland, in the county of Kerry, 8 miles S. W. of Killarney.

BARNAUL, a town of Siberia, on the west side of the Ob, 100 miles S. S. E. of Kolyvan. It is situated on the Ob, in the government of Kolyvan, famous for its silver and copper mines, which also produce gold. These mines are much more productive than those of Nerthinsk; for the pits hitherto opened in the latter have no continued or steady veins, are never powerful, and seldom terminate in large veins, are always poorer as they proceed in depth, and change their contents at every fathom. The mines of Barnaul belong to the crown. About 48,000 boors earn their capitation tax in working at them, over and above the miners and other workmen properly belonging to them. The quantity of gold produced at Barnaul and the Shlangenber from 1745 to 1780, amounted to 686 pood, 16 pounds, 49 solotniks of pure gold.

BARNEGAT INLET, called in some maps *New Inlet*,

is the passage from the sea into Flat-bay sound, on the south-eastern coast of New Jersey, 68 miles N. E. from cape May. N. lat. $39^{\circ} 47' 30''$. W. long. $74^{\circ} 13'$.

BARNER, JAMES, in *Biography*, born at Elbing, in West Prussia, in 1641, applied himself early to the study of chemistry, in which he made such progress, that in 1670 he was engaged to give lectures in that art at Padua. After residing some years in that university he went to Leipzig, where he practised medicine with success. Retiring at length to Elbing his native country, he died there in 1686. Barner left several works on the subject of chemistry, but that by which he is principally known is his "*Chymia philosophica, cum doctrina salium, medicamentis sine igne culinari parabilibus*;" published at Nuremberg 1689, three years after his death, a work rather curious than useful. Haller Bib. Med. Eloy Dict. Histor.

BARNERA, in *Geography*, a small island of Scotland, near the west coast of Lewis, separated from the main land by a strait, called Loch Barnera, about a mile wide. N. lat. $58^{\circ} 25'$. W. long. $7^{\circ} 3'$.

BARNES, JOSHUA, in *Biography*, an English divine and classical scholar, was born in London in 1654, and educated in grammar-learning at Christ's hospital, where he was distinguished by his proficiency in Greek, and by some Latin and English poems. In 1671, he was admitted a fervitor of Emanuel college in Cambridge; and in 1678, he was elected a fellow of the same college. In his numerous writings, which were critical, poetical, and historical, he displayed more industry and fancy than taste and judgment. His memory was singularly retentive, so that he could write and converse in the Greek tongue with great readiness; though Dr. Bentley sarcastically remarked of him, that he understood as much Greek as a Greek cobbler. But if he excelled in tenaciousness of memory, he was notoriously deficient in solidity of judgment; and therefore some person recommended this pun to be inscribed upon his monument:

"Joshua Barnes,

"Felicis Memoriae, Judicium expectans."

The enthusiasm of his temper was manifested in various singularities of opinion and conduct. Believing that charity never fails in this life of obtaining due recompence, he has given his only coat to a common beggar; and he used to recite strange stories of some unexpected remuneration which he had derived from charities of this kind. Of his talents and learning, and particularly of his acquaintance with the Greek language, he was vain and boastful; and at the same time he was prone to depreciate and abuse others. Of his works the most respectable were his editions of the Greek classics; and these he dedicated, without much appropriate selection, to persons of high rank. In 1695, he was elected Greek professor of the university of Cambridge. In 1700, he married a widow with a handsome jointure, who is said to have made the first advances; and, with a view to her amusement, and in order to induce her to supply him with money towards defraying the expence of his edition of Homer, he wrote a copy of English verses, designed to prove that Solomon was the author of the poems under Homer's name. He died in 1712, and was buried at Hemingford in Huntingdonshire, where a curious monument was erected to him by his widow, with an inscription partly in Latin and partly in Greek Anacrotics. The following memorandum is annexed: "Mr. Barnes read a small English bible, that he usually carried about him, one hundred and twenty-one times over at leisure hours." Of his numerous publications, the principal are the following: "*A Poetical Paraphrase on the History of Esther*," intitled, "*Actus 2071200*," or "*The Courtier's Looking-glass*, &c." The story is paraphrased in Greek

Greek verse, with a Latin translation in the opposite page and Greek scholia; to which is added, "An Homeric Parody on the same Story." "The History of that most victorious monarch Edward III. &c.;" Camb. fol. 1688. This historical work, for which the author's talents seem to have been very ill adapted, abounds in false inferences and tedious digressions; and in long and elaborate speeches, after the manner of Thucydides and other ancient historians, which seem to be the result of his own imagination; the whole displaying neither the judgment of a politician, nor the taste of a good writer. "Euripidis quæ extant omnia, &c." Camb. fol. 1694. Besides a correction of the text of Euripides, this edition contains a preliminary dissertation on the ancient Greek tragedy, and another on the life and writings of Euripides. "Anacreon Teius, &c." Camb. 1705. In this edition, the poems of Anacreon are corrected, and much enlarged by the addition of several whole pieces and fragments. The life of Anacreon is annexed; and in the Prolegomena, the author treats of the antiquity and invention of lyric poetry, and the peculiar character and metre of that poet. The dedication to the duke of Marlborough is followed by a Greek Anacreontic ode upon the victory at Blenheim. The editor has also subjoined the epigrams of the ancients and moderns upon Anacreon, and some odes of his own composition under the title of "Anacreon Christianus." "Homeri Ilias et Odyssea, &c.;" 2 vols. 4to. Camb. 1710. This edition is furnished with an exact Latin translation, with the ancient Greek scholia, many notes upon the text and scholia, and various readings; to which are subjoined the "Batrochomyomachia," the "Hymns and Epigrams," the "Fragments," and "Two Indexes." This edition of Homer has been generally esteemed as correct and complete; though in the *Acta Eruditorum* for Jan. 1711, there are some objections against it, which have been ascribed to Dr. Bentley. Barnes's editions of the Greek classics have of late years been sinking into disrepute; and modern critics place little confidence in his judgment or sagacity. He has been charged, in some of his various readings, by the learned Dr. Clarke, with audacity and unskilfulness.

As for his other works, both in prose and verse, it would be tedious to enumerate even their titles; and this is the less necessary, as they are now consigned to total oblivion. *Biog. Brit.*

BARNET, denominated also *High*, and *Clipping Barnet*, in *Geography*, a town of England, situated in the hundred of Caltho and county of Hertford, 11 miles north of London. It has a market on Mondays, which has existed since Henry II.; and here are also three fairs annually. At this town, which is a great thoroughfare, the north road divides for York and Liverpool. Being situated upon an eminence, the prospects are extensive and agreeable; but there are no public buildings worth notice, except the church and a grammar school. The latter was founded by queen Elizabeth, and afterwards endowed by alderman Owen of the Fishmongers' company of London, for the education of nine children gratis. There are likewise alms houses for widows, founded by James Ravencroft Esq. and his wife, in 1672. At the twelfth mile stone beyond the town, is erected a pillar to commemorate a signal battle fought on that spot on Easter day, April 14, 1471, between the house of York headed by Edward IV., and that of Lancaster conducted by the stout earl of Warwick, who, with many of the nobility and nearly 10,000 men, were slain. This was a decisive victory for the Yorkists, as it firmly established Edward IV. on the throne; although in a subsequent battle at Tewkesbury, the queen of Henry VI. and her son were taken prisoners. Barnet is governed by a magistrate, high constable, and

other officers; and a court leet is held at Easter. In the town are 225 houses, inhabited by 1258 persons. Salmon's History of Hertfordshire.

BARNET, a township of America, in Caledonia county, and state of Vermont, containing 477 inhabitants, and distant 112 miles N. E. from Bennington.

BARNEVELDT, JOHN-OLDEN, in *Biography*, a minister of Holland, eminently distinguished by his abilities and patriotism, was born in 1547. In his early negotiations on behalf of the states general with France, England, and the neighbouring powers, he gave great satisfaction to those who employed him, and gained equal credit and esteem in the judgment of Henry IV. and queen Elizabeth. As grand pensionary of the states of Holland, he obtained extensive influence; and firmly attached to the liberty of his country, he observed the growing power of the house of Orange, directed by the warlike and aspiring prince Maurice, with jealousy and apprehension. Amidst the collision of different parties, he was regarded as the leader of the opposition to the measures of that prince. The authority of Maurice depended, in a great measure, on the continuance of the war with Spain, and Barneveldt was very desirous of terminating it. By his zealous endeavours to effect this purpose under the mediation of the king of France, he incurred the violent odium of the adverse party. At length, however, he succeeded by obtaining, in 1609, a truce for 12 years; the first article of which recognized the independency of the united states. Soon after this event, the disputes between the Arminians and Calvinists, or Remonstrants and Contra-remonstrants, furiously agitated the Dutch provinces. Barneveldt, inclined to the former, and the advocate of toleration, exerted himself in procuring for the Arminians or Remonstrants that liberty of conscience to which they had an equitable claim. Prince Maurice placed himself at the head of the other party, which was the most numerous; and probably took pleasure in the opposition and calumny encountered by Barneveldt in his endeavours to promote the cause of religious freedom and moderation. At this time, notwithstanding the suspicions excited against Barneveldt, as if he wished to subject his country again to the yoke of Spain, he was essentially serving it by negotiating with James I. the restoration of the towns of Flushing, Rammekens, and the Brille, which had been put into the hands of Elizabeth as security for the money which she had lent to the states. Barneveldt's success in this negotiation added James to the number of his enemies.

The religious disputes, which had been appeased in the province of Holland by the influence of Barneveldt, prevailed so much in the other provinces, that a national synod was assembled at Dordrecht in 1618 in order to bring them to a termination. To this synod the kings of England and France, and most of the Protestant states of Europe, sent deputies; and the Arminians, who did not comply with the citation to appear before this assembly, incurred a formal condemnation. On this occasion, Barneveldt, Grotius, and other Remonstrant chiefs of the anti-Orange party, were arrested and imprisoned in the castle of Louvenstein. Barneveldt, however, was the devoted victim. Many accusations were alleged against him, as the fomentor of the disturbances that had occurred at Utrecht, and as an enemy to the public liberty; and being tried by a court, composed chiefly of his enemies, and admitting inadequate proofs, he was capitally condemned. Prince Maurice, to whom application was made from various quarters in his favour, remained inexorable; and he would only promise a pardon upon condition of its being solicited by the family of Barneveldt: but they refused to do an act, which would imply the guilt of their

their venerable chief. Barneveldt prepared for death, and without asking any favour for himself, merely solicited the protection of his children. On the morning of execution, Barneveldt proceeded to the scaffold with a serene countenance; but being somewhat disturbed on his arrival, he exclaimed with uplifted eyes to heaven, "O God! what is man!" Having prayed with the minister who attended him, he rose from his knees with composure, declared his innocence to the spectators, and desired the executioner to perform his office. His head was struck off at a blow, in his 72d year, May 13th 1619. The popular hatred soon subsided; his memory was revered as that of the purest of patriots and most respectable of men, and his death left a stain on the character of prince Maurice which all his great qualities and services were not sufficient to efface. The states of Holland, in the register of his death, added these words, which may serve as a testimony to his character; "He was a man of great conduct, industry, memory, and prudence; yes, singular in all. Let him who standeth, take heed lest he fall. God be merciful to his soul! Amen." "Never (says the French ambassador De Maurier) was there so wise and virtuous a man as M. de Barneveldt. He had a majestic presence, and said much in few words, with a grave and succinct eloquence." Barneveldt left two sons in considerable employments: who being deprived of them by prince Maurice, engaged in a conspiracy against his life. One was beheaded, and the other made his escape. When the mother of him who was taken and condemned, fell at the feet of Maurice supplicating his life, the prince expressed his surprize that she who had refused to ask her husband's pardon, should condescend to intercede on behalf of her son. "I did not ask pardon for my husband," said the mother with a noble spirit, "because he was innocent. I ask it for my son, because he is guilty." *Mod. Un. Hist. Gen. Biog.*

BARNEVELT'S ISLANDS, in *Geography*, are two small flat islands, close to each other, on the west side of Terra del Fuego, partly surrounded by rocks, and 2½ leagues distant from the straits of Le Maire. S. lat. 55° 47'. W. long. 66° 58'.

BARNEVILLE, a town of France, in the department of the Channel, and chief place of a canton in the district of Valognes, 5¼ leagues S.S.W. of Cherbourg.

BARNBIARD, in *Ornithology*, is an aquatic bird, of which Oviedo speaks in his "Hist. des Indes," book 14. c. 2.; but which it is impossible to ascertain from what that author has said of it.

BARNSLEY, in *Geography*, a small market town of England, in the west riding of Yorkshire, 15 miles from Doncaster, and 176 north-west from London. It is situated on the side of a hill, and about 5 furlongs in extent. The town, though well built of stone, is called Black Barnsley; probably from its smoking furnaces, or rather from the sooty soil of the moors with which it is surrounded. The land is very prolific in wheat and other grain, and coal is also exceedingly plentiful. The abundance of stone, timber, iron-stone, &c. and the cheap living necessary for population, render this place very appropriate for any kind of trade. At present its wire works are supposed the best in the kingdom: and the wire is of two sorts; the hard, made into teeth for cotton and wool cards, the soft for stocking-frame needles. Processes of a lesser kind are weaving of linen, in which 500 looms are employed, and a glass manufactory of black bottles. Barnsley has a well built church, which is a chapelry under Silkeston, a free grammar school, a market on Wednesday, and three fairs: the population of this township consists of 722 houses, inhabited by 3606 persons.

BARNSTAPLE, a very ancient corporate town and sea-port in the county of Devon, is situated in a broad and fertile vale on the eastern bank of the river Taw, and bounded by a semicircular range of hills. It is one of the neatest and most reputable towns in the north of the county; the streets being spacious and regular, and the buildings respectable. Before the conquest, Barnstaple was a royal demesne; and king Athelstan is reported to have constituted it a borough, and to have erected a castle near the confluence of the rivers North Yeo and Taw: no remains, however, of this fortress continue, except a high artificial mound. In Domesday book it is noticed as containing "forty burgesses within the borough, and nine without;" and the inhabitants were exempted from serving on any expedition or being otherwise taxed, but in equal proportion with Exeter and Totness. The town was re-incorporated by Henry I. but still retaining some of its ancient feudal privileges, which 250 of the common burgesses at this day possess: namely, a right to vote with the corporation for two members of parliament.

The corporation is composed of a mayor, high steward (at present earl Fortescue), two bailiffs, two aldermen, a recorder, twenty-two common-council men, and other officers. King James I. ratified and confirmed the privileges of the town by a charter in the eighth year of his reign; and we find by authentic documents, that the first return for members to parliament was made in the 23d of Edward I.

Respecting the trade of Barnstaple, its harbour is so shallow that vessels of more than 200 tons cannot enter; yet the baize, silk-socking, and waistcoat manufactories still give life to the place, and in a great degree compensate the loss of its former woollen trade; added to this, the beautiful scenery and pleasantness of the neighbourhood, and the cheapness of living, have induced many independent families to make it their sole residence.

A noble quay along the river is terminated by a handsome portico, over the centre of which is placed a statue of queen Anne. Over the river is a stone bridge of sixteen arches. The church is a stately building, with a handsome spire and a good organ; formerly it contained several chantries. We find also that in the town Judhall de Totness founded a priory for Cluniac monks, which, at the dissolution, was valued at 123l. 6s. 7d. per annum.

The grammar school is famous for having upon its foundation several eminent characters; bishop Jewel and his opposite professor Harding, the poet Gay, Dr. Masgrave, &c. For the useful education of the lower class of inhabitants, a charity school is erected over the north gate; near which is a pleasant walk, denominated Northern Hay, from the fine prospects it commands, as well as an agreeable promenade.

The number of houses in the whole parish is estimated at 653, and the inhabitants at 3748. N. lat. 51° 15'. W. long. 4° 5'.

BARNSTAPLE BAY, is an opening in the Bristol channel, formed by the union of the rivers Taw and Towridge. This is the common bay or road to the towns of Barnstaple and Biddeford, on their respective rivers.

BARNSTAPLE, a county of America, lying upon the peninsula, the point of which is cape Cod, the south-eastern point of Massachusetts bay, opposite cape Ann. This county is about 65 miles long, and in various parts from 3 to 6 and 9 miles broad. It contains 11 townships, and the plantation of Mashpee, having 2543 houses, and 17,354 inhabitants. Barnstaple was made a shire in 1685. See *Cape Cod*.

BARNSTABLE, the *Mattachese* or *Mattachest* of the ancient Indians, is a port of entry and post town, and the shire town of Barnstable county in North America. It extends across the peninsula, and is washed by the sea on the north and south, having Sandwich and the district called Marshpee or Mashpee on the west; and is about 5 miles broad and 9 long; 67 miles S. E. from Boston. Sandy-neck on the north shore, running east almost the whole length of the town, forms the harbour, and embosoms a large body of salt-marsh. The harbour is about a mile wide and four long; and the tide rises in it from 8 to 14 feet. Its bar, running off N. E. from the neck several miles, prevents the entrance of large ships; but small vessels may pass any part of it at high water. There is another harbour on the south, called Lewis's bay. Its entrance is within Barnstable, and extends almost 2 miles into Yarmouth. This harbour is commodious and safe, and is completely land-locked. In Barnstable there are about 20 or 30 ponds. The land here produces about 25 bushels of Indian corn to an acre, and rye and other grain in proportion. Wheat and flax are cultivated; the latter with success. From 12 to 18 000 bushels of onions are raised for the supply of the neighbouring towns. The fishery, which is annually increasing, employs about 100 men. The people, who are in number about 2510, are generally healthy; and many instances of longevity occur. Many of the farmers are occasionally seamen, and many mariners and masters of vessels, who sail from other ports, are furnished by this town. N. lat. 41° 45'.

BARNSTEAD, a township of America, in Strafford county, New Hampshire, containing 807 inhabitants; 32 miles N. W. of Portsmouth, and 16 E. by S. from Canterbury on Connecticut river.

BARNSTORF, or **BERNDORF**, a town of Germany, in the circle of Westphalia, and county of Diepholz, 8 miles north of Diepholz.

BARNTRUP, a town of Germany, in the circle of Westphalia, and county of Lippe, 4 miles N. E. of Blomberg.

BARNWELL, a village situated about half a mile north-east of Cambridge, in England, was formerly of great consequence from its ancient priory, which, at the dissolution, was valued at 351l. 15s. 4d. The village has suffered very much by fire. Barnwell has a fair kept in its neighbourhood, commencing annually on Midsummer-day, and continuing a fortnight. This fair derives its origin from a custom of the children in the neighbourhood assembling on Midsummer-eve at Barn's-well. A number of pedlars resorted to the spot, and exposed their merchandize for sale, so early as the reign of Henry I.: the articles brought being mostly pottery, the festival obtained the appellation of *Pot Fair*. It appears, however, to have assumed its legal form in the reign of Henry III. by whom it is said to have been chartered and granted to the priory. The fair is still proclaimed on Midsummer-eve, and the field in which it is held is called Midsummer Green. But Barnwell is most famous for the great assemblage of merchandize annually held in a large meadow, called *Sturbridge Fair*; the origin of which Dr. Stukely was induced to ascribe to his hero Carausius: it is however evident that king John granted the whole for the use and maintenance of an hospital for lepers who had an ancient chapel here; and the chaplain claimed the dues, till Hen. VIII. in consideration of 1000 marks paid by the corporation of Cambridge, gave them the grant of the fair, which was confirmed by Elizabeth. The field in which it is held is about half a mile square, having the rivers Cam and Sture on its northern and eastern sides. The

booths are built in regular order, each row being particularly named, as Ironmonger's row, Bookseller's row, &c.: the centre is called the Duddery, and chiefly occupied by drapers, mercers, and wholesale dealers in cloaths. Sturbridge fair is solemnly proclaimed on the 18th of September, by the vice-chancellor, proctors, and other officers of the university; and afterwards by the mayor and aldermen. The stated time for its continuance is fourteen days. Dramatic exhibitions are forbidden within nine miles of the university, except during this fair and the week preceding. This was formerly the greatest mart in England; but its business declining, owing to the circulation of commerce throughout the country, its consequence is very much diminished. Beauties of England and Wales, vol. ii.

BARO, or **BARON**, **PETER**, in *Biography*, a professor of divinity in the university of Cambridge, was born at Ellampes in France, and educated for the law at Bourges; but driven from his country to England by the persecution of the Protestants in the reign of queen Elizabeth. By the recommendation of lord Burleigh, he was elected professor at Cambridge in the year 1574. He was attacked by the rigid Calvinists on account of the reputed laxness of his sentiments concerning the doctrines of predestination and justification; and a complaint was preferred against him as an encourager of the spread of Pelagianism in the university, to archbishop Whitgift in 1595, which produced the *Lambeth ARTICLES*, that were made use of to silence him. But as he continued to preach his former doctrines, he was cited before the vice-chancellor, and several articles were exhibited against him. The proceedings against him, however, were prevented by the interference of the chancellor lord Burleigh, and he was recommended by his learning and character to the protection of the archbishop Whitgift. At length wearied by the persecution of his enemies, he retired from the university to London, where he died three or four years afterwards. A collection of his theological works in Latin was published at London in 1579, fol.; as were also some detached pieces in that language, and some sermons, &c. in English. *Biog. Brit.*

BAROACH, **BROACH**, or **BARUH**, the ancient *Barygaza*, in *Geography*, a town of Hindostan, in the country of Guzerat, lying in the route from Surat to Amedabad, and seated on the great river Nerbuddah, about 25 miles from its mouth. Baroach has been, in different ages, a port common both to Nehrwahle, the capital of Guzerat, and Tagara, supposed to be the modern Dowlatabad. The former was eight journies, the latter ten, from Baroach. It is situated about 217 British miles north from the Plithana of Arrian, or the modern Pultana; and all kinds of mercantile goods throughout the Deccan were anciently brought to Tagara, and from thence conveyed on carts to Baroach or Barygaza across the Balla-Gaut mountains. Baroach is famous for its manufacture of very fine bafts and other cottons; and the water of the river Nerbuddah is said to have a peculiar property for bleaching of cloth to a perfect whiteness. Agates are likewise an article of trade in this place; which are brought from the mountains near Brampour, and are mostly disposed of at Cambaya. The fortress of Baroach is large and square, standing upon a hill, which is the only eminence for many miles, and might be made very strong. The Dutch factory was established here in 1617, but is in a low state. N. lat. 21° 45'. E. long. 72° 58'.

BAROCCIO, **FREDERICK**, in *Biography*, an eminent painter of history and portrait, was born at Urbino in 1528, and instructed in the principles of painting by Battista Vene-tiano, and in those of perspective by his uncle Bartolomeo Genga. Having availed himself of these instructions till his

20th year, he removed to Rome, and pursued his studies with such assiduity and success, that he became one of the most graceful painters of his time. At Rome he was particularly encouraged by the protection of cardinal della Rovere, and by the commendation of Michael Angelo. On his return to Urbino he gained great applause by several pictures, and more especially by that of a St. Margaret, which induced pope Pius IV. to invite him to Rome, and to employ him, in conjunction with Federigo Zuccherò, in the decorations of his palace of Belvedere. It has been said, that his superior merit excited the jealousy of his brother artists to such a degree, that they gave him poison at an entertainment. Whether this be true or not, his health declined; and for the recovery of it, he was under a necessity of recurring to his native air, and of intermitting his labours. However, by due attention, his life was prolonged to the advanced age of 84 years. His genius principally inclined him to the painting of religious subjects; and his works evince that it was his chief ambition to imitate Correggio in his colouring, and Raphael in his manner of designing. It is easy to observe, that he endeavoured to resemble the former illustrious artist in the sweetness of his tints, in the harmony of his colouring, in the graceful airs of the heads, in the disposition of his draperies, and the forms of his Bambinos, though he sometimes expressed the muscular parts of the human body too strongly. He seldom painted any historical figure without having either modelled it in wax, or placed some of his disciples in such attitudes as he wished to represent: his sister was the model for the Madonnas, and her child for his Bambinos. He is said to have employed seven years in painting at Assise, the birth-place of St. Francis, a picture called the "Pardon," in which the figure of the saint kneeling, by the force of shade, seems to rise from the canvas. The works of this master are numerous; the principal of which are at Rome, in the Belvedere, and several churches; at Urbino, Assise, Cortona, Arezzo, and other towns in Italy; in the gallery of Florence; the Escorial; and the duke of Orleans's collection. Baroccio engraved four of his own pieces with peculiar spirit, and more than thirty more have been published by different engravers. Pilkington and Strutt.

BAROCHE, LA, in *Geography*, a town of France, in the department of the Orne, and chief place of a canton in the district of Domfront; 4 miles S. S. E. of Domfront.

BAROCO, in *Logic*, denotes the fourth mode of the second figure of syllogisms.

A syllogism in baroco has the first proposition universal and affirmative, but the second and third particular and negative; and the middle term, the attribute or predicate in the two first.—For example:

“BA Every virtue is attended with discretion:

RO Some kinds of zeal are not attended with discretion:

CO Therefore some kinds of zeal are not virtues.”

“BAR Nullus homo non est bipes:

OC Non omne animal est bipes:

O Non omne animal est homo.”

BAROLITE, in *Mineralogy*. See **WITHERITE**.

BAROMETER, compounded of βαρος, *weight*, and μέτρον, *measure*, an instrument for measuring the weight of the atmosphere and its variations, in order chiefly to determine the changes of weather, and the heights of mountains, &c.

The barometer is frequently confounded with the *baroscope*, though somewhat improperly; the latter, in strictness, being an instrument that barely shews an alteration in the weight of the atmosphere: but it is one thing to know that the air is heavier at one time than another, and another to

measure how much that difference is; which is the business of the barometer.

The barometer is founded on the Torricellian experiment, as it is called from its inventor Torricelli, who, in consequence of the previous suggestion of Galileo, with regard to the ascent of water in a pump, upon drawing up the piston, proceeded, in 1643, to fill with mercury a glass tube, hermetically sealed or close at one end, the other end being open and immersed in a basin of stagnant mercury. Judging that, in the former case, the water was sustained in the pump by the pressure of the air on the water in the vessel, in which its open end was immersed, and that it was the measure of this pressure, he hence concluded that mercury would in like manner be supported by it in the tube, and at a height which was also the measure of the air's pressure, or about 13 times less than water. His experiment was completely verified; for he observed that the mercury descended in the tube, and finally settled at the perpendicular height of 29½ Roman inches, whether the tube was vertical or inclined, according to the known laws of hydrostatical pressure. This famous experiment was repeated and diversified in various forms, with tubes filled with other fluids, such as water, wine, oil, &c.; and the result being the same, the weight and pressure of the air were established beyond contradiction or doubt. Those who had any remaining doubts were completely satisfied by a beautiful experiment exhibited by M. Auzout. He provided a small box or phial EFGH (*Plate IX. Pneumatics, fig. 74.*) into which he inserted two glass tubes, AB, CD, each three feet long, in such a manner that they were firmly fixed at one end, and reached nearly to the other end. The tube AB was open at both ends, and CD was closed at D. This apparatus being completely filled with mercury, by unscrewing the tube AB, and filling the box and the tube CD, and then screwing in the tube AB and also filling it, was inverted, whilst a finger was held on the orifice A, and set upright in the manner exhibited in *Fig. 75*, immersing the orifice A of *Fig. 74*, or *a* of *Fig. 75*, in a small vessel of quicksilver. Upon this, the mercury ran out at the orifice *a*, till its surface *mn* within the phial descended to the top of the tube *ba*. The mercury began also to descend in the tube *dc* (*Fig. 75.*) corresponding to DC in *Fig. 74*, and flowing over into the tube *ba*, escaped at *a*, till that in *dc* was very nearly on a level with *mn*. In *ba*, the mercury stood at *k*, 29½ inches above the surface *op* of the mercury in the cistern, as in the Torricellian tube. Indeed, this whole apparatus may be first considered as a Torricellian tube of an uncommon form, from which the mercury would flow out at *a*. But when any of it escaped, a vacant space would be left above *mn*, and the mercury in the tube *dc* would also descend, and running over into *ba*, supply its waste, till *dc* became almost empty, and could no longer supply *ba*. The inner surface being therefore depressed as much as possible, till it became level with *b*, no more mercury could enter into *b*, and yet its column being too heavy to be supported by the pressure of the air on the mercury in the cistern *op*, it must descend in *ba*, till it finally settled at the height *kc*, equal to that of the mercury in the Torricellian tube. In this state if a small hole *g* were made in the upper cover of the box, the external air would rush in by its weight, and press on the mercury in the box. This pressure would immediately cause the mercury to rise in the tube *dc* to *l*, 29½ inches above *mn*. It likewise presses on the mercury at *k* in the tube *ba*, balancing the pressure of the air on the mercury in the cistern. The mercury in the tube, therefore, must descend to the bottom by its own weight. By this experiment the doctrine of the gravity and pressure

of the air is decisively established. See AIR, *Weight of*, and *Experiments with the Air-Pump*.

Notwithstanding the satisfactory demonstration of the air's pressure, afforded by the Torricellian experiment, some attempts were made by the advocates of a plenum for evading it, and for explaining the phenomena of this experiment by some other hypothesis. Accordingly Linaus contended, that in the upper part of the tube there is a film, or "rope of mercury," whence his hypothesis was called "the funicular hypothesis," which extended through the seeming vacuum; and that, by means of this rope, the rest of the mercury was suspended, and kept from descending into the basin. In proof of this absurd and ridiculous hypothesis he alleged the following experiment. Take, says he, a small tube, about 20 inches long, open at both ends; fill it with mercury, and stop the lower orifice with your thumb. Then closing the upper end with your finger, immerse the lower end in stagnant mercury; and upon the removal of your thumb, there will be a sensible suction of the finger into the tube; and both the tube and mercury will adhere to it so closely, that they may thus be carried about the room. Hence he infers, that the internal cylinder of mercury in the tube is not sustained by the pressure of the external air; for this, he argues, would not account for the strong suction, and the adhesion of the tube to the finger. If the tube be not quite filled with mercury, but a small interval of air left at the top, after the tube is immersed in stagnant mercury, a considerable suction will be perceived. From these experiments, which actually furnish evidence of the air's pressure, the funicular hypothesis of Linaus derived support for some time; but it has been long since exploded. When it was perceived that the mercury on the top of a high mountain subsided, and stood at a lower height than on a plain, and that in the vacuum of an air pump it descended to the bottom of the tube, this hypothesis could have no advocates. However, an experiment mentioned by Mr. Huygens, in which mercury well purged of its air remained suspended in a tube at the height of 75 inches, suggested a more considerable difficulty, which has been variously solved. See an account of it, under the article TORRICELLIAN. For an explication of the phenomenon of a siphon, which discharges water under the exhausted receiver of an air-pump, see SIPHON.

BAROMETER, Common, the Construction of it.—A glass tube (AB, *Plate IX. Pneumatics, fig. 76.*) open at one end, and hermetically sealed at the other A, having its diameter about one third or one fourth of an inch, and its length thirty-three or thirty-four inches, is filled with mercury so justly as not to have any air over it, nor any bubbles adhering to the sides of the tube; which is best done by means of a small paper or glass funnel, with a capillary tube. If a small bubble of air be moved backwards and forwards in the tube, it will help to clear the mercury; which will appear, when pure, like a polished rod of steel. The orifice of the tube, filled after this manner, so as to overflow, is then closely pressed by the finger, so as to exclude any air between it and the mercury, and thus immersed in a vessel of a convenient diameter, so however as not to touch the bottom: at the distance of twenty-eight inches from the surface of the mercury are fixed two plates, CE and DF, divided into three inches, called "the scale of variation," and these again subdivided into any number of small parts. Lastly the tube is inclosed in a wooden frame, to prevent its being broken; the basin, though open to the air, secured from dust; and the barometer is complete. As the lowest station of the mercury in this country is about 28 inches, and the highest

about 31 inches above the surface of the mercury in the basin, the former point is the lowest in the scale of variation, and in the common barometers, called "weather-glasses," it is marked *stormy*; and the latter is marked on one side *very dry* for the summer, and on the other *very hard frost* for the winter. To the next half-inch below this highest point are annexed *set fair* on the one side, and *set frost* on the other. At the height of 30 inches, the word *fair* is marked on one side, and *frost* on the other; at 29½ is marked the term *changeable* both for summer and winter; at 29 are inscribed on the one side *rain*, and on the other *snow*; and at 28½ inches are the words *much rain* on one side, and *much snow* on the other. Each of these larger divisions is usually subdivided into ten parts, and by means of a small sliding index adapted to the instrument, the ascent or descent of the mercury may be ascertained for any number of divisions. Each of these tenths is again sometimes divided into ten more, or hundredths of an inch, by means of a sliding piece of brass, with a scale called NONIUS and VERNIER; for the use of which see these terms, and the sequel of this article.

As the common barometer is the best, and most to be depended upon in accurate observations, it may be proper to add some directions for preparing it: they are collected chiefly from the publications of Muschenbroeck, Defaguliers, and De Luc on this subject. It appears from many experiments, that the mercury stands higher in tubes of a larger, than in those of a narrower bore; and therefore when observations are made with different barometers, some regard should be paid to the difference of their diameters, and it would be desirable to have them constructed of tubes of the same diameter. The bore of the tube should be large, in order to prevent the effects of the attraction of cohesion; not less than one fourth of an inch: but if they are one third of an inch diameter, they are better. If a cistern be used as a reservoir for the stagnant mercury, it should be large in proportion to the diameter of the tube, at least ten times greater; that the addition or subtraction of the mercury, contained between the greatest and least altitudes, may not sensibly affect its depth; for the numbers marked on the scale annexed to the tube, shew their distance from a fixed point, and cannot truly indicate the height of the column above the mercury in the cistern, unless its surface coincide with this point, and be immovable. In order more effectually to preserve the lower surface at the same height from divisions on the scale affixed to the instrument, the father of the late Mr. George Adams first applied to the barometer a floating gage, by means of which the same screw that renders the barometer portable, regulates the surface of the mercury in the cistern, so that it is always at the place from whence the divisions on the scale commence. See PORTABLE BAROMETER.

The tube should be preserved free from dust till it is used; and for this purpose it may be hermetically sealed at both ends, and one end may be opened with a file, when it is filled. If this precaution has not been observed, the inside should be well cleaned, by washing it with alcohol highly rectified, and rubbing it with a little piston of shammy leather fastened to a wire. The mercury should be pure; and may be purged of its air, by previously boiling it in a glazed earthen pipkin covered close; and when the tube has been uniformly heated and rendered electrical by rubbing it, the hot mercury should be poured into it in a regular current, through a glass funnel with a long capillary tube, so that the air may not have room to pass between the parts of the quicksilver. M. De Luc directs, as Mr. Orme had practised many years ago in the construction of his improved diagonal barometers, that the mercury should be boiled in the tube,

tube, as the most effectual method of purging it of its air and moisture. The process is briefly this: he chooses a tube of $2\frac{1}{2}$ lines or 3 lines bore, and not exceeding half a line in thickness; he fills it with mercury within two inches of the top, and holds it with the sealed end lowest in an inclined position over a chafing dish of burning charcoal, presenting first the sealed end to the fire, and moving it obliquely over the chafing-dish. As the mercury is heated, the air bubbles appear like so many studs on the inner surface of the tube, and gradually running into one another, ascend towards the higher parts of the tube, which are not heated; here they are condensed and almost disappear; and after successive emigrations, they acquire a bulk by their union, which enables them at length to escape. When the mercury boils, its parts strike against each other, and against the sides of the tube, with such violence, that a person unaccustomed to this operation is ready to apprehend their force to be sufficient to break the tube. The mercury is thus freed from all the heterogeneous particles contained in it, together with their surrounding atmospheres, and the air which lines the inside of the tube, which cannot be easily expelled in any other way, is discharged; when this last-mentioned stratum of air is thus expelled, the tube may be afterwards emptied, and filled even with cold mercury, and will be found nearly as free from air as before. The mercury in the tubes thus prepared by a determinate quantity of heat, will rise higher than in those of the common sort, and the barometers will more nearly correspond with each other; whereas there will be a difference of six or eight lines in the ascent of the mercury in common barometers. When this operation is completed, the mercury generally remains suspended at the top, and will not descend to its proper level without shaking the tube to bring it down. The tubes, which should be chosen not less than three feet long, may now be filled to their proper length.

Barometers of this kind rose uniformly in a heated room; whilst the mercury in those that had been prepared in the common way descended, and in different proportions. When the room cooled, the former descended uniformly, and corresponded with each other; the latter rose with the same irregularity with which they had before descended, nor were they found, at the close of the experiment, to stand at the same relative heights as they did at the beginning of it. The reason of which is obvious, from the effects of heat on the air remaining in unequal quantities in the tubes in the one case, and on the purer mercury in the other.

Another circumstance that requires attention in the construction and use of barometers is the temperature of the air; for unless this remains the same, the dimensions of a given quantity of mercury will be variable; and the altitude of the mercury will be an uncertain measure of the weight of the atmosphere, because it is dilated by heat, and contracted by cold, when probably its weight and pressure are unchanged. M. De Luc attended particularly to this circumstance, and contrived to estimate the effects of heat on the quicksilver in the barometer, when it is used for accurate observations, by means of a thermometer; the scale of which is divided in such a manner as to indicate, with little labour of calculation, the correction to be made on account of heat. As an increase of heat that is sufficient to raise the mercury in the thermometer from the point of melting ice to that of boiling water, will lengthen the column of mercury in the barometer six lines, he divides each line in the scale of the barometer into four parts, each of which may be easily subdivided into four lesser parts, or sixteenths of a line. The scale of the thermometer marking the interval between the freezing and boiling points, and answering to the six lines

of the barometer, is divided into ninety-six equal parts, each of which will correspond to the sixteenth of a line in the motion of the mercury in the barometer dilated by heat, which must be added to or subtracted from the height of the mercury in the barometer, for every degree of the variation of the thermometer so graduated. A scale of this kind, continued above boiling or below freezing water, is annexed to his *Portable BAROMETER and THERMOMETER*. M. de Luc prepared two barometers with their respective thermometers graduated in the manner above explained; he placed one pair in the cellar of one house, and the other pair in the upper room of another house in a lower situation, so as to be exactly on a level with the cellar: he found that the thermometer in the room rose nine degrees, and the barometer $\frac{9}{76}$ of a line higher than those in the cellar; whence he shews, that without allowing for the effect of heat, the difference in the heights of these two barometers would have indicated a difference of about forty-five feet in the heights of these two places, though they were exactly on the same level. M. De Luc's *Recherches*, &c. vol. i. p. 193—199. See *ATMOSPHERE*, and the sequel of this article.

M. Prius, an artist in Holland, has made an improvement in the reservoir of the simple barometer, by means of which the mercury contained in it is constantly kept at the same level; but the construction is difficult, and therefore it has not been generally adopted. De Luc's *Recherches*, &c. vol. i. p. 35.

The *common barometer* is a kind of chamber barometer, and serves for observing in a fixed place the changes of the atmosphere; but is not adapted for removal from one place to another, and in this respect differs from the portable barometer. It is sometimes combined with a thermometer, and sometimes also with an hygrometer, and in this form prepared by the mathematical instrument makers. An instrument of this kind constructed by Messrs. Jones, opticians in London, is exhibited in *fig. 84*, and consists of a barometer *d*, thermometer *aa*, and hygrometer *c*, all in one mahogany frame. The thermometer or hygrometer of this apparatus may be conveniently separated from the frame, and occasionally used apart, if it be necessary. The thermometer is separated by means of two screws *aa*; and the hygrometer, by unscrewing a brass pin at the back of the frame. The index of the hygrometer is set at any time, merely by moving with the finger the brass wheel seen at *c*; and the two sliding indexes of the barometer and thermometer are moved by rack-work, set in action by the key *g* placed in the holes *b* and *l*. The divisions of the barometer plate *b* are in tenths of an inch, from 28 to 31 inches; and these are subdivided into hundredths, by the Nonius or Vernier scale, placed on a sliding slip of brass, similar to that of the common barometers. This Vernier (*fig. 85*) is divided into ten equal parts, all of which are equal to eleven of those on the scale of inches, or to eleven tenths. By this artifice, the height of the mercury at *E* is evident merely by inspection to the one hundredth part of an inch. For understanding this, it should be considered that $\frac{1}{10}$ th part of $\frac{1}{10}$ th of an inch is the $\frac{1}{100}$ th part of an inch. But every tenth of an inch in the scale *B* is divided into ten equal parts by the slip or Vernier *A*; for since ten divisions on that exceed ten on the scale by one division, that is, by one tenth of an inch, one division on the Vernier will exceed one division on the scale by one tenth part, and two divisions on the Vernier will exceed two on the scale by two tenths, and so on; therefore every division on the Vernier will exceed the same number of divisions on the scale by so many tenths of a tenth, or by so many hundredth parts of an inch. Consequently the ten equal divisions of an inch on the scale *B* must be considered as so

many ten hundredth parts of an inch, and numbered accordingly, 10, 20, 30, 40, &c. parts of an inch; then the Vernier gives the unit to each ten, thus: set the index very accurately to the top of the surface of the mercury E; and if at the same time, the beginning of the divisions at C coincide with a line of division in the scale B, then it shews the altitude of the mercury in inches and tenths of an inch exactly. But if the index line C of the Vernier fall between two divisions or tenths on the scale B, then there will be a coincidence of lines in both at that number of the Vernier, which shews how many tenth parts of that tenth the index of the Vernier has passed the last decimal division of the scale. E. G. Suppose the index of the Vernier were to point somewhere between the sixth and seventh tenth above 30 on the scale; then, if by looking down the Vernier, you observe the coincidence at number 8, this shews that the altitude of the mercury is 30 inches, and 68 parts of a hundredth of another inch, or simply thus, 30,68 inches. See *VERNIER*. The screw *f*, in *fig. 84*, serves to press the mercury up into the tube, when the instrument is to be moved, and thus to render the instrument a *portable barometer*.

The barometer belonging to the house of the Royal Society is of the cistern kind; and the Hon. Mr. Cavendish prefers this form to that of the syphon kind, because both the trouble of observing and the error of observation are less, as in the latter we are liable to an error in observing both legs. Moreover he remarks, that the quicksilver can hardly fail of settling more exactly in the former than in the latter; for the error in the settling of the quicksilver can proceed only from the adhesion of its edge to the sides of the tube. In the latter the adhesion may take place in two legs, but in the former only in one; and besides, as the air has necessarily access to the lower leg of the syphon barometer, the adhesion of the quicksilver in it to the tube will most probably be different according to the degree of dryness or cleanness of the glass. It is true, as M. De Luc observes, that the cistern barometer does not give the true pressure of the atmosphere; the quicksilver in it being a little depressed on the same principle as in capillary tubes. But it appears by calculation, that in the barometer of the society, the error arising from the alteration of the height of the quicksilver in the cistern can scarcely ever amount to so much as $\frac{1}{1000}$ th of an inch. In this barometer, the height of the quicksilver is estimated by the top of its convex surface, and not by the edge where it touches the glass; the index being properly adapted for that purpose; and this manner of observing is more accurate than the other. *Phil. Trans. vol. lxvi. p. 381.*

As soon as it was discovered that the different heights of the mercury indicated by the barometer were in some degree connected with the state of the weather, and that it might be applied to the purpose of a "weather-glass," many attempts were made to render the changes in it more sensible, and so to measure the variations of the weight of the atmosphere more accurately; and these attempts have given rise to a great number of barometers of different structures, deviating from the simplicity of the common barometer, and at the same time less accurate. Hence the wheel barometer, diagonal barometer, horizontal barometer, pendant barometer, &c.

Des Cartes suggested the first method of increasing the apparent sensibility, or enlarging the scale of variation, of the barometer, though he did not live to execute it. He proposed a tube AB (*Plate IX. Pneumatics, fig. 77.*) about twenty-seven inches long, terminating in a cylindrical vessel CD: one half of which vessel, connected above with a long tube of a very small bore, sealed at top, and exhausted of its air,

was to be filled with water extending up into the small tube; the other part of the vessel, and the lower part of the tube, were to be filled with mercury. Whenever the mercury rose in the cylinder, it would force up a proportional quantity of water into the narrow tube, where it would have a considerably larger range than that of the mercury in the cylinder: neglecting the weight or pressure of the water, the motion of the water and of the mercury would be in the inverse ratio of the squares of the diameters of the vessels containing them. But the water presses on the mercury according to its height; and therefore if the whole range of the mercury in the cylinder, or in a common barometer, were supposed to be two inches, the specific gravity of water to that of mercury as 1 to 14, and the difference between the diameters of the cylinder and tube a *maximum* or infinite, then the entire scale of variation in this instrument would be twenty-eight inches; or the extent of this scale would be to that of the common barometer in the inverse ratio of the specific gravity of water to that of mercury. It is evident that in practice it would be somewhat less than twenty-eight inches. Huygens constructed a barometer of this kind; but here, though the column suspended was larger, and consequently the variation greater, yet the air imprisoned in the water getting loose by degrees, filled the void space in the top, and so ruined the machine.

Huygens then thought of changing the construction of the barometer, and of placing the mercury at top, and the water at bottom, in the following manner: ADG (*fig. 78.*) is a bent tube hermetically sealed in A, and open in G; the cylindrical vessels BC and FE are equal, and about twenty-nine inches apart; the diameter of the tube is about a line, that of each vessel fifteen lines, and the depth of the vessels is about ten; the tube is filled with mercury (the common barometer standing about twenty-nine inches) which will be suspended between the middle of the vessel FE, and that of the vessel BC; the remaining space to A being void both of mercury and air; lastly, common water, tinged with a sixth part of *aqua regis* to prevent its freezing, is poured into the tube FG till it rises a foot above the mercury in DF.

When the mercury rising above the level of that contained in FE, through the tube AD, becomes a balance to the weight of the atmosphere; as the atmosphere increases, the column of mercury will increase, consequently the water will descend; as the atmosphere again grows lighter, the column of mercury will descend, and the water ascend. This *double barometer*, as it was called, which is nearly the same with that of Dr. Hooke, will therefore discover much minuter alterations in the air than the common one; for, instead of two inches, the fluid will here vary two feet; and by enlarging the diameters of the cylinders, that variation may be still increased; but it has this inconvenience, besides others, that the water will evaporate, and so render the alterations precarious; though the evaporations be in some measure prevented by a drop of oil of sweet almonds swimming at top: the column of water will likewise be sensibly affected by heat and cold.

The *double barometer* of Dr. Hooke was invented in the year 1668, and is described in the *Phil. Trans. N^o 185.* The invention was claimed by Huygens and De la Hire; but it sufficiently appears, that Hooke was the original inventor. (See De Luc's *Recherches*, vol. i. p. 18.) This consists of a compound tube ABCDEFG (*fig. 79.*), of which the parts AB and DE are equally wide, and EFG as much narrower as it is proposed to enlarge the scale. The parts AB and EG are made as cylindrical as possible.

The

The part HBCDI is filled with mercury, having a vacuum above in AB. IF is filled with a light fluid, and FC with another light fluid, which will not mix with that in IF. The cistern G is of the same diameter with AB. It is plain that in this instrument the range of the separating surface at F must be as much greater than that of the surface I, as the area of I is greater than that of F; and this ratio may be selected at pleasure. This barometer is the best of those with an enlarged scale; it is most delicately moveable, and is the best adapted to a chamber for the purpose of amusement, by observations on the changes of the atmospheric pressure. It rises or falls by the slightest breeze, and is continually in motion. The most accurate method for graduating such a barometer would be to make a mixture of vitriolic acid and water, which should have $\frac{1}{15}$ of the density of mercury. Then, let a long tube stand vertical in this fluid, and connect its upper end with the open end of the barometer by a pipe with a branch to which the mouth may be applied. By sucking through this pipe, the fluid will rise both in the barometer and the other tube; and the rise of ten inches in this tube will correspond to a descent of one inch in the common barometer. Thus every point of the scale may be adjusted in due proportion to the rest. But nothing except actual comparison can determine what particular point of the scale corresponds to some determined inch of the common barometer. When this is done, the whole becomes equally accurate. It is liable, however, to several inconveniences. Although the heights of the contained fluids are always the same in a constant temperature, nevertheless their weight or pressure on the base is not always the same on account of the difference of their specific gravity; and though there be no sensible difference in the action of these fluids against the sides of the tube, yet there is a continual action, and therefore the movements of this barometer cannot be so free as those of the simple barometer. These differently coloured liquors mingle with one another, and form a deposit on the sides of the tube, so that their respective boundaries cannot always be ascertained with precision. The fluid of this barometer is also subject to evaporation; and heat acts upon the fluids which it contains. On account of these and such defects, others have had recourse to an

Horizontal or rectangular barometer ABCD (fig. 80.); the tube whereof is bent in form of a square BCD: at the top of its perpendicular leg it is joined to a vessel or cistern AB; and its variations accounted on the horizontal leg CD. Now here the interval, or space of variation, may be made of any extent at pleasure, and so the minutest change in the air become sensible. For the diameter of the tube CD being given, it is easy to find the diameter of the vessel AB, so as that the scale of descent in the tube DC shall have any given proportion to the scale of ascent in the vessel AB; the rule being that the diameter of the vessel is to that of the tube in a subduplicate reciprocal ratio of their scales.

The diameters then of CD and AB being given, together with the scale of ascent of the mercury in the vessel, the scale of mercury in the tube is found thus: as the square of the diameter of the tube is to the square of the diameter of the vessel, so reciprocally, is the scale of mercury in the vessel, to the scale of mercury in the tube.

Cassini was the first inventor of this kind of barometer, though the same construction had been thought of, and first published by M. J. Bernouilli, in the year 1710.

This and the preceding contrivance of Huygens are founded on a theorem in hydrostatics; viz. that fluids, having the same base, gravitate according to their perpen-

dicular altitude, not according to the quantity of their matter; whence the same weight of the atmosphere supports the quicksilver that fills the tube ACD, and the cistern B, as would support the mercury in the tube alone.

This last, however, with its excellencies, has great defects: for, by reason of the attraction between the parts of the glass and of the mercury (which Dr. Jurin has shewn to be considerable), with the length of the scale (consequently the quantity of motion), and the attrition against its sides, especially in sudden rises and descents, the mercury breaks, some parts of it are left behind, and the equality of its rise and fall ruined. Some therefore prefer the

Inclined barometer, or diagonal, of Sir Samuel Moreland, where the space of variation is considerably larger than in the common one, and yet the rise and fall more regular than in the others.—Its foundation is this; that in a Torricellian tube BC (fig. 81.) inclined at any angle to the horizon, the cylinder of mercury equivalent to the weight of the atmosphere, is to a cylinder of mercury equivalent to the same in a vertical tube, as the length of the tube BC to the perpendicular height DC.

Hence, if the height DC be triple, subquadruple, &c. of the length of the tube, the changes in the diagonal barometer will be triple or quadruple, &c. of the changes in the common barometer. This barometer will scarce allow its tube to be inclined to the horizon at a less angle than 45° , without undergoing the inconveniency of the horizontal one.

Mr. Orme, in order to obviate some of the objections to which the diagonal construction of the barometer is liable, purified the quicksilver from its dross and earthy particles by distillation; and when the tube was filled with a certain quantity of mercury, discharged the remaining air by an intense heat sufficient to make the mercury boil; and he continued this operation for four hours. In the process, an innumerable quantity of small particles were emitted, and when no more bubbles rose in the tube, the mercury appeared extremely bright, but sunk lower in the tube than when it was first put in, by two inches. Phil. Trans. Abr. vol. viii. p. 455.

The *wheel barometer* was a contrivance of Dr. Hooke, in 1668, to make the alterations in the air more sensible; the foundation of this is the common vertical barometer, with a large ball above, and turned up at the lower end, with the addition of a couple of weights A and B (fig. 82.) hanging on a pulley, the one of them playing at liberty in the air, the other resting on the surface of the mercury in the inverted tube, and rising and falling with it.

Thus is the motion of the mercury communicated, by means of the pulley, to an index which turns round a graduated circle; and thus the three inches of vertical ascent are here improved to five, six, or more, at pleasure.

But the friction of the axis of this index, and more especially when it has contracted some rust, generally renders this sort of barometer useless; and, at best, the graduation of inches on the circle can only be considered as a scale of motions of the mercury in its tube; for the great variation of the height of the surface of the mercury in the tube below will perpetually falsify the inches and tenths upon the plate above. In a just or standard barometer, the inferior surface of the mercury in the cistern or tube below should either be invariable, or reducible by a pressing screw to a fixed or determinate gauge point.

The wheel barometer has lately been obtruded upon the public by the strolling Italian hawkers in our streets; but the imperfect manner in which these barometers are constructed,

fructed, as well as their defective principle, renders them mere mechanical pictures, and not scientific instruments, in the parlour.

An instrument of this kind, with considerable improvements, has been constructed by Mr. Fitzgerald, F. R. S. It is furnished with two pulleys that move on friction-wheels; each of which turns an index on the centre of a graduated circle. The smaller circle is four inches in diameter, and divided into three equal parts, each of which is again subdivided decimally; and the changes corresponding to the rise or fall of the mercury from 28 to 31 inches, are marked on the margin of it, as they are on the scales of common barometers. The larger circle is divided into 300 equal parts; and being about 30 inches in circumference, the index belonging to it will mark distinctly the 600th part of an inch in the rise or fall of the mercury. On the centre of this circle two registers are fixed, which are placed along the index when the instrument is adjusted; one of them is carried round with the index, and left behind on its return; so that their distance will determine the limits of the variation from one observation to another. Phil. Transf. vol. lii. part i. N^o 29. Ibid. vol. lx. N^o 10.

The *pendant barometer*, invented by M. Amontons, in 1695, is a machine rather pretty and curious than useful (fig. 83). It consists of a conical tube, placed vertically, its upper and smaller extreme hermetically sealed; it has no vessel or cistern, its conical figure supplying that defect: for when filled, like the rest, there will be as much mercury sustained as is equivalent to the weight of the atmosphere; and as that varies, the same mercury takes up a different part of the tube, and so becomes of a different weight.

Thus, when the weight of the atmosphere is increased, the mercury is driven up into a narrower part of the tube; by which means its column is lengthened, and, for the reason just given, its weight increased. Again, the atmosphere decreasing, the mercury sinks into a wider part of the tube; by which means its column is again shortened, and its pressure accordingly weakened. Thus, the same mercury is still a balance to the atmosphere under all its variations. The inconvenience in this barometer is, that to prevent the mercury and air from changing places, the bore of the tube must be very small; which smallness of the bore renders the friction so sensible as to impede its playing.

The *marine barometer* is a contrivance of Dr. Hooke, in 1700, to be used at sea, where the motion of the waves renders the others impracticable; it resembles that of Amontons invented in 1705. This is nothing more than a double thermometer, or a couple of tubes half filled with spirit of wine; the one hermetically sealed at both ends, with a quantity of common air inclosed; the other sealed at one end, and open at the other.

Now the air, we know, is able to act on the spirit of wine, and raise it, two ways; partly by its gravity, as in the Torricellian tube; and partly by its heat, as in the thermometer. If then the two tubes be graduated, so as to agree with each other at the time when the air is inclosed, it will easily follow, that, wherever the two agree afterwards, the pressure of the atmosphere is the same as at the time when the air was inclosed. If in the thermometer open to the air the liquor stand higher, considering at the same time how much the other is risen or fallen from the other cause of heat or cold, the air is heavier; on the contrary, when it is lower, compared with the other, the air is lighter than at the time when the instrument was graduated. Here the spaces answering to an inch of mercury will be

greater or less, according to the quantity of the air inclosed, and the smallness of the tubes; and they may be increased almost in any proportion. But it must be remembered, that the density and rarity of the air, on which this machine is founded, do not only depend on the weight of the atmosphere, but also on the action of heat and cold. This, therefore, can never be a just barometer; but may properly enough be called a manoscope, or instrument to shew the density of the air. See MANOMETER.

Nevertheless, the instrument is said to be of good use in giving notice of all bad weather at sea, as also of veerable winds, and of the neighbourhood of ice. Phil. Transf. N^o 429. p. 133.

Improved marine barometers. In the best of these barometers, Messrs. W. and S. Jones apply a small ivory floating gage, or index, to an aperture in the cistern of mercury below; the index floats on the mercury; a mark is cut on its stem, and another on the socket in which it moves; these two marks are brought to a coincidence by turning the screw below; and thus the surface of the mercury in the cistern is made to be just to the divisions of the plate above.

Mr. Nairne, an ingenious artist in London, constructed a marine barometer for captain Phipps, in his voyage to the north pole; the upper part of which was a glass tube, about three tenths of an inch in diameter, and four inches long, to which another glass tube was joined with a bore about $\frac{1}{10}$ th of an inch diameter. These two glass tubes formed the tube of this barometer, which was filled with mercury, and inverted into a cistern of the same. The instrument was fixed in gimbals, and kept in a perpendicular position by a weight fastened to the bottom of it, and was not liable to the inconvenience attending the common barometer at sea. Voyage to the North Pole, p. 123.

The *marine barometer*, as it is commonly constructed, differs from the common one merely in having the bore of the tube small for about two feet in its lower part; but above that height it is enlarged to the common size. Through the small part of the instrument the mercury is prevented from ascending too hastily by the motion of the ship, and the motion of the mercury in the upper wide part is consequently lessened. Much depends upon the proper suspension of this instrument: and Mr. Nairne has found by experiment the point from which it may be suspended so as not to be affected by the motion of the ship.

We shall here subjoin the description of two kinds of *marine barometers*, which are constructed by Messrs. W. and S. Jones of London, and which seem to be well adapted to marine purposes. In *Plate X. fig. 86.* one of these barometers is represented as supported on its stand in the cabin of a ship, ready for observation: *a b c* are the folding mahogany legs, about three feet each in length; *A* is a circular brass plate, with two hollow brass tubes fixed perpendicularly upon it; a gimbal brass ring with its axis is made to turn between these tubes; and on two spiral springs placed in the tubes, the axis of the gimbal ring acts. The barometer frame *B* is attached inwards to this ring by an axis and two screws, in a position at right angles to the axis in the uprights, yet left free to move; the three legs are screwed down to the floor of the cabin. Whatever heave or motion the ship may receive, the barometer, by its action on the gimbal, on the springs in the tubes, and on its axis, will always tend to keep its vertical position, and as speedily as possible attain to a state of quiescence; *d* is a screw that serves to move the sliding Nonius scale upon the plate above; *e* is a small mahogany door that is shut over the tube and plate, to defend them when this instrument is not in use. On the top of the frame there is a pendent brass ring *g*, by which the barometer,

rometer, without the stand, may be hung on a neck against the wall of a room or side of a cabin: the screw *f* at the bottom of the frame serves to compress the mercury in the cistern, in order to force it up to the top of the tube, as in the common barometers. By the barometer's being moveable from its stand, and the stand folding up into a small extent, the whole apparatus may be packed up in a convenient narrow deal case for carriage.

The principal inconvenience that has been found to attend this barometer has been the ground occupied by the feet in the cabin when the instrument is in use, this being sometimes more than a mariner can spare; and besides, it is liable to be stumbled against by a heedless by-stander. To obviate this inconvenience, another principle of mounting has been adopted (see fig. 87.). The barometer in this figure is in every respect the same as the preceding, but its mode of suspension is as follows: on the sides of the frame, at its centre of gravity, are fixed two iron centres; as an axis to these there is fixed a brass frame *a*, and brass pillar; one end of this pillar is framed on a vertical joint, having only one motion upwards, and checked by a brass socket shoulder below, to keep the pillar and arm in an horizontal position; thus causing the barometer to be suspended in a vertical direction. The length of the pillar and arm together is about 14 inches; the joint socket at the end of the pillar is attached to a strong round brass plate *b*, about 3 inches diameter, with four counterfunk holes for receiving screws, by which the whole instrument may be screwed securely to the side of a cabin, in any convenient or safe situation. When the instrument is in a state of suspension for observation, it will be about 15 inches from the side of the cabin, and being also free to act on its axis of suspension at *a*, it is evident that notwithstanding any common motion or reel of the ship, the barometer will tend to keep a vertical position, or to recover it after having been agitated. The only circumstance to be apprehended is the possibility that, by a violent motion, the bottom of the barometer should strike against the side of the cabin, and endanger the glass tube; but this is easily avoided by fixing a temporary leathern cushion against that part of the cabin against which alone it could strike. When the instrument is not wanted for any observation, while the ship is in motion, it may be moved upwards upon the joint, and it will close to the side of the cabin or wall, and may be buckled fast by a leather strap and buckle *c* attached for that purpose (see fig. 86.), and thus be out of any danger from any person suddenly or unguardedly coming to it; and it will answer the purpose of the common chamber barometer.

M. Passement, an ingenious artist at Paris, accommodates the barometer to nautical uses, by twisting the middle part of the common barometer into a spiral, consisting of two revolutions: by this contrivance, the impulses which the mercury receives from the motions of the ship, are destroyed by being transmitted in contrary directions. De Luc's Recherches, &c. vol. i. p. 34.

The *statical barometer*, or *baroscope*, used by Mr. Boyle, Otto de Gueric, &c. consisted of a large glass bubble, about the size of a large orange, and blown so thin as to weigh only 70 grains. This being balanced by a brass weight, in a nice pair of scales, that would turn with the 30th part of a grain, was found to act as a barometer; for this obvious reason, that the surface of the bubble was opposed to a much larger portion of air than that of the brass weight, and consequently was liable to be affected by the varying specific gravity of the atmosphere; so that when the air became specifically light, the bubble descended, and *vice versa*. Thus (says Mr. Boyle) he could perceive variations

of the atmosphere no greater than such as would have been sufficient to raise or depress the mercury in the common barometer an 8th part of an inch. Nevertheless, the two bodies being of equal gravity, but unequal bulk, if the medium in which they equibonderate be changed, there will follow a change of their weight; so that if the air grows heavier, the greater body, being lighter in specie, will lose more of its weight than the lesser and more compact; but if the medium grow lighter, then the bigger body will outweigh the less.

The barometer of Mr. Caswell, described in the Philosophical Transactions, has been much commended for its accuracy; the structure of it is as follows: suppose *ABCD* (fig. 88.) a bucket of water, wherein is the barometer *x r e z y o s m*, consisting of a body *x r s m*, and a tube *e z y o*. The body and tube are both concave cylinders, communicating with each other, and made of tin, or rather glass. The bottom of the tube *e y* has a lead weight to sink it, so that the top of the body may just sail even with the surface of the water, by the addition of some grain weights on the top. The water, when the instrument is forced with its mouth downwards, gets up into the tube to the height *y o*. There is added on the top a small concave cylinder, which we call the *pipe*, to distinguish it from the other at bottom which we call the *tube*: this pipe is to sustain the instrument from sinking to the bottom; *m d* is a wire, *m S* and *d e* two threads oblique to the surface of the water, performing the office of diagonals. Now, while the instrument sinks more or less by the alteration of the gravity of the air, there where the surface of the water cuts the thread is formed a small bubble, which ascends up the thread as the mercury of the common barometer ascends, and *vice versa*.

This instrument, as appears from a calculation which the author gives, shews the alterations in the air more accurately than the common barometer, by no less than 1200 times. He observes, that the bubble is seldom known to stand still a minute; that a small blast of wind that cannot be heard in a chamber will make it sink sensibly, and that a cloud always makes it descend, &c.

Mr. Rowning (Phil. Transf. N^o 427. and System of Philosophy, part ii. diff. 4.) has described a barometer, in which the scale of variation may be infinitely extended. *ABCD* (fig. 89.) is a cylindrical vessel, filled with a fluid to the height *H*, in which is immersed the barometer *S P*, consisting of the following parts: the principal one is the glass tube *T P* (represented separately at *t p*), whose upper end *T* is hermetically sealed; this end does not appear to the eye, being received into the lower end of a tin pipe *G H*, which in its other end *G* receives a cylindric rod or tube *S T*, and thus fixes it to the tube *T P*. This rod *S T* may be taken off, in order to put in its stead a larger or a lesser as occasion requires. *S* is a star at the top of the rod *S T*; and serves as an index by pointing to the graduated scale *L A*, which is fixed to the cover of the vessel *ABCD*. *M N* is a large cylindrical tube made of tin (represented separately at *m n*), which receives in its cavity the smaller part of the tube *T P*, and is well cemented to it at both ends, that none of the fluid may get in. The tube *T P*, with this apparatus, being filled with mercury, and plunged into the basin *M P*, which hangs by two or more wires upon the lower end of the tube *M N*, must be so poised as to float in the liquor contained in the vessel *ABCD*; and then the whole machine rises when the atmosphere becomes lighter, and *vice versa*. Let it now be supposed that the fluid made use of is water; that the given variation in the weight of the atmosphere is such, that by pressing upon the surface of the water at *H*,
the

the surface of the mercury at X may be raised an inch higher (measuring from its surface at P) than before; and that the breadth of the cavity of the tube at X , and of the basin at P , are such, that by this ascent of the mercury there may be a cubic inch of it in the cavity X more than before, and consequently in the basin a cubic inch less. Now, upon this supposition, there will be a cubic inch of water in the basin more than there was before, because the water will succeed the mercury to fill up its place. Upon this account the whole machine will be rendered heavier than before by the weight of a cubic inch of water; and therefore will sink, according to the laws of hydrostatics, till a cubic inch of that part of the rod WS , which was above the surface of the water at W , comes under it. Then if we suppose this rod so small that a cubic inch of it shall be 14 inches in length, the whole machine will sink 14 inches lower into the fluid than before; and, consequently, the surface of the mercury in the basin will be pressed more than it was before, by a column of water 14 inches high. But the pressure of 14 inches of water is equivalent to one of mercury; this additional pressure will make the mercury ascend at X as much as the supposed variation in the weight of the air did at first. This ascent will give room for a second cubic inch of water to enter the basin; the machine will therefore be again rendered so much heavier, and will subside 14 inches farther, and so on *in infinitum*. If the rod was so small that more than 14 inches of it were required to make a cubic inch, the variation of this machine would be negative with respect to the common barometer, and instead of coming nearer to an equilibrium with the air by its ascent or descent, it would continually recede farther from it: but if less than 14 inches of rod were required to make a cubic inch, the scale of variation would be finite, and might be made in any proportion to the common one.

The same author has also contrived a *compound barometer*, in which the scale of variation shall bear any proportion to that of the common one. ABC (fig. 90.) is a compound tube hermetically sealed at A , and open at C ; empty from A to D , filled with mercury from thence to B , and from thence to E with water. It appears from the nature of a siphon, that if H, B, G , be in the same horizontal line, the column of mercury DH will be in equilibrio with the column of water GE , and a column of air of the same base, and will therefore vary with the sum of the variations of these. He has subjoined a calculation, whence it appears, that if the tubes AF and FC are of an equal bore, the variation in this is less than that of the common barometer, in the proportion of 7 to 13; but if the diameter of AF be to that of FC as 5 to 1, the variations will be to those of the common barometer, as 175 to 1; but if the proportion of the diameters be greater, the variations will be infinite in respect to those of the common barometer. Of the practical utility of this construction the author had no experience. Rowning's Nat. Phil. part ii. diff. 4.

Another contrivance for enlarging the scale of the barometer is exhibited in fig. 91. AB is the tube of a common barometer, open at B , and sealed at A , suspended at the end of a lever which moves on the fulcrum E . D is a glass tube fixed, and serving for a cistern, which is wide enough to admit the free motion of the barometrical tube AB . AB , when filled with mercury, is nearly counterbalanced by the long end of the lever. When the atmosphere becomes lighter, the mercury descends in the long tube, and the surface of the mercury rising in the cistern, pushes up the tube AB , which causes the lever to preponderate, and to point out by its index moving along a circular arc, the most minute variations. This apparatus, however, is subject to the

inconvenience of the friction as well as weight of the lever, when put in motion by the rise or fall of the tube AB .

Whilst some have endeavoured to enlarge the variations of the barometer, others have endeavoured to make it more convenient, by reducing the length of the tube. M. Amontons, in 1688, first proposed this alteration in the structure of barometers, by joining several tubes to one another, alternately filled with mercury and with air, or some other fluid; and the number of these tubes may be increased at pleasure: but the contrivance is more ingenious than useful.

M. Mairan's reduced barometer, which is only three inches long, serves the purpose of a *manometer* in discovering the dilatations of the air in the receiver of an air-pump; and instruments of this kind are now generally applied to this use. See *Air-Pump*, and *GAGE*.

For an account of a self-registering barometer by the Rev. Arthur McGwire, see Irish Transactions, vol. iv. p. 141.

The barometer lately invented by Alexander Keith, Esq. F. R. S. and F. A. S. Edinb. marks the rise and fall of the mercury from two different times of observation. This instrument consists of a glass tube $ABCD$ (fig. 92.) bent in the manner represented in the figure, open at D , and hermetically sealed at A . The length from A to B is 8 inches, and its calibre about $\frac{1}{4}$ of an inch; from B to C it is $31\frac{1}{2}$ inches long, and about $\frac{1}{8}$ inch calibre; and from C to D $4\frac{1}{2}$ long, and $\frac{1}{2}$ inch calibre. The tube is filled with mercury, the length from A to E being $29\frac{1}{2}$ inches. When the tube is hung perpendicularly, the mercury will fall from B towards E , leaving a vacuum from A to B . When the atmosphere becomes heavier, the mercury falls in the tube DC ; and when lighter, it rises. The range of the scale is about 3 inches, being equal to that of a common barometer of the best construction, which has a basin with a very broad surface. This instrument moves in a direction contrary to that of the common barometer, the one rising while the other falls. The tube DC is represented on a larger scale in fig. 93.; F is the float, having the float-wire fixed to it, terminating in a knee at a right angle between the indexes LL , where it embraces a very small wire stretched along the scale, and thereby raises or lowers them as the mercury rises or falls in the tube DC . The barometer is prepared for observation, by bringing down the one and raising the other index, till both touch the knee of the float-wire. When next observed, the upper index will point out the greatest depression of the mercury, or lightness of the atmosphere; and the lower the greatest rise of the mercury, or weight of the atmosphere since the scale was prepared. By these means, the variations of the atmosphere are more truly pointed out than by the common barometer; for it often happens that during tempestuous weather, or before it, the mercury both rises and falls within a few hours, or during the night time; which variations cannot be noticed by any of the barometers now in use. The sudden fall and rise, or even the rise and fall of the mercury, always denote an extraordinary agitation in the atmosphere. In a common barometer the mercury may be at the same height in the morning that it was the night before; which leads to a conclusion that as there has been no agitation of the mercury, there will be calm or settled weather: but this new barometer will often shew in such cases, that the one float has been raised $\frac{1}{2}$, and the other depressed as much; which instead of indicating calm weather denotes that tempestuous weather may be expected.

The weight of the atmosphere at great heights might be discovered by suspending this instrument to an air-balloon. Edinb. Transf. vol. iv. 1798.

The *portable barometer* is so contrived, that it may be carried from one place to another without being disordered; and since it has been applied to the mensuration of altitudes, it has undergone many improvements in its construction and appendages. The most common instrument of this kind consists of a tube of a proper length accurately filled with mercury; the lower end of the tube is glued to a wooden reservoir, the bottom of which is formed of leather; the superfluous mercury descends into this reservoir, and the air, by pressing upon the flexible leather, keeps the mercury suspended at its proper height. This reservoir is concealed from the eye by a neat mahogany cover or box; through the bottom of which passes a screw, having upon its end a round plate, which presses upon the leather bag and forces the mercury to the top of the tube, so that it is prevented from shaking or breaking the tube by dashing against the top of it when the instrument is removed from one station to another. This apparatus is placed in a frame, having on its upper part a silvered brass plate with a scale of inches and tenths reckoned from the surface of the mercury in the cistern; and close to the line of inches is a slit or groove for sliding the nonius scale up and down. On the left hand side of the plate are engraved the words *fair, changeable,* and *rain*. When this barometer is used, the screw at the bottom of the frame is to be so turned that the mercury may fall to its proper height, and indicate the corresponding changes in the weight of the air. The upper edge of the index is adjusted so as to coincide with the surface of the mercury in the tube, and then the nonius scale will shew the height of the column. Before every observation, the frame should be gently struck with the knuckles in order to disengage the quicksilver from the tube. This barometer does not admit of being adjusted in such a manner, that the divisions on the scale may be at that height from the mercury in the cistern, which is expressed by the numbers affixed to them; because the mercury as it falls in the tube rises in the reservoir, and when it rises in the tube it sinks in the reservoir; and thus its distance is perpetually varying from the divisions on the scale. Besides the tension of the leather occasions a considerable resistance to the pressure of the atmosphere. The portable barometer has of late received a variety of improvements, the principal of which are here recited.

The portable barometer of Mr. Ramsden is constructed with his usual accuracy. The principal parts of this instrument are a simple straight tube, fixed into a wooden cistern, which for the convenience of carrying is shut with an ivory screw; and that being removed, it is open when in use. Fronting this aperture is distinctly seen the coincidence of the gage-mark with a line on the rod of an ivory float, swimming on the surface of the quicksilver, which is raised or depressed by a brass screw at the bottom of the cistern. From this, as a fixed point, the height of the column is readily measured on the scale attached to the frame, always to $\frac{1}{1000}$ th part of an inch, by means of a nonius moved with rack work. A thermometer is placed near the cistern, whose ball was usually inclosed within the wood work; but that defect has been since remedied. The three-legged stand, supporting the instrument when in use, serves as a case for it when inverted and carried from place to place. Two of these barometers after the quicksilver in them hath been carefully boiled, being suffered to remain long enough in the same situation, so as to acquire the same temperature, usually agree in height, or rarely differ from each other more than a few thousandth parts of an inch, which are to be allowed for in calculating altitudes, as well as in estimating the rate of expansion.

The next instrument of this kind which we shall mention and minutely describe, is that of M. de Luc. This portable

barometer consists of a tube composed of two pieces, or of two tubes (see *fig. 94.*): one of these tubes is thirty-four French inches in length, and straight from the top but bent at the bottom in form of a siphon; the other tube is eight inches long, open at both ends, of the same diameter with the former, and communicating with its open end by means of a cock. When this barometer is carried from one place to another, it is inverted very slowly to prevent the intrusion of any air; the quicksilver retires into the long tube on which the key of the cock is turned; and to preserve the cock from being too much pressed by the mercury, the barometer is conveyed in this inverted posture. When an observation is to be made, the cock is first opened: the tube is then turned upright very slowly, to prevent, as much as possible, such vibration of the mercury as would disturb the observation; and according to the weight of the atmosphere, the mercury will fall in the longer branch, and rise up through the open cock into the shorter. The cock is wholly made of ivory, except the key; and is composed of two small ivory cylinders *a* and *b*, open through their whole length and admitting the free passage of the tube, and of a square piece of ivory *c*, thirteen lines long, as many broad, and nine lines thick, having two holes, one for receiving the key *f d e*, and the other in a vertical direction with two short tubes, *h, i*, at its extremity, adapted to the holes in the small ivory cylinders above mentioned. The most essential part of the cock is the key, which serves to open and close the communication between the two glass tubes. The part of the key that turns within the cock and passes through the opening in *c* to *f*, is formed of cork, and the outward part or handle *d e*, is made of ivory. The cork is firmly fastened to the ivory by means of a broad thin plate of steel, which cuts both the ivory and cork, lengthwise, through the centre, and reaches within to the hole of the key. This plate serves to counteract the flexibility of the cork, and to make it yield to the motion of the handle, although it is compressed in a very considerable degree by the ivory, in order to preserve it tight. But that this compression may not contract the diameter of the hole of the key, it is lined with a thin hollow ivory cylinder of the same diameter with the tubes. The extremities of the tubes are wrapped round with the membrane employed by the gold-beaters covered with fish-glue in order to fix them tight, the one in the lower, and the other in the upper, end of the vertical canal of the cock. On the upper end of the shorter tube is fixed, during the intervals of observation, a kind of funnel, with a small hole in it which is shut with an ivory stopple. This is intended for keeping the tube clean, for replacing the mercury that may have escaped through the cock in consequence of any dilatation; and also for replacing the mercury taken out of the shorter tube, after shutting the cock, when any observation is completed; because when the mercury is left exposed to the air, it contracts on its surface a dark pellicle that sullies both itself and the tube. The shorter tube should be cleansed occasionally, by a little brush of sponge fixed to the end of a wire adapted to the purpose.

The barometer thus constructed, and described more in detail by the author (*Recherches*, vol. ii. p. 6, &c.) is placed in a long box of fir, the two ends of which are lined within with cushions of cotton covered with leather. This box may be carried on a man's back like a quiver in its natural position, though the inverted position is to be preferred, either walking or riding; and

should be defended from the rain by a cover of wax-cloth. In order to prevent its being unduly affected by heat, it should be kept at a distance from the body of the man who carries it, and be protected from the sun by an umbrella, when it is near the place of observation. To the apparatus a plummet should be annexed, in order to ascertain its vertical position, and a three-legged frame or tripod will serve to keep it firm in that position at the time of observation. The scale of this barometer is annexed to the long tube; it commences at a point on a level with the upper end of the short one, and rises in the natural order of the numbers to 21 inches. Below the above point, the scale is transferred to the short tube; and descends upon it in the natural progression of the numbers to 7. The interval of 27 inches, comprehended between the point marked 20 in the upper tube, and that which corresponds to 7 in the lower, is divided into 27 parts, which are inches. These inches are again divided into lines, fourths, sixteenths, and even thirty-second parts of lines. The adhesion and friction of the mercury in the tubes will not allow of a more minute subdivision. As the mercury falls in the one tube, it will rise in the other; and therefore the total altitude will be found by adding that part of the scale which the mercury occupies in the long tube, to that part of it which the mercury does not occupy in the short one. In estimating, however, the total fall or rise in the long tube, every space must be reckoned twice; because in barometers of this kind, half the real variation only appears in one of the branches.

One of the thermometers, exhibited in *fig. 95*, is designed for ascertaining the corrections that are to be made in the height of the mercury on account of any variation in the temperature of the air by heat and cold. For this purpose it is placed near the middle of the longer tube, that it may partake as much as possible of its mean heat. The ball is nearly of the same diameter with that of the tube of the barometer, that the dilatations or condensations of the fluids contained in them may more exactly correspond; and this ball should also be enclosed in wood that it may participate, as well as the barometer, of the heat of the bottom of the box. The scale of the thermometer is divided into 96 parts, between the points of boiling water and melting ice. M. de Lue, having found that an increase of heat, sufficient to raise the thermometer through this interval, augmented the height of the mercury in the barometer, when it was at 27 French inches, precisely six lines, was led to divide it into 96 equal parts; so that one of these parts corresponded to $\frac{1}{16}$ th of a line in the height of the barometer: and this quantity therefore must be added to or subtracted from the said height, for every degree of variation of the thermometer thus graduated. He placed the term 0, one eighth part of the above interval above the lower point: so that there are 12 degrees below and 84 above it; because as 27 French inches express the mean height of the barometer, so the 12th degree above freezing is nearly the mean altitude of the thermometer. Hence by taking these two points, the one for the mean altitude and the other for the mean heat, there will be fewer corrections necessary for reducing all observations to the same state, than if any higher or lower points had been taken. The divisions above 0 or *zero*, are considered as positive and denoted by +, and those below as negative and expressed by -.

If the barometer remains at 27 French inches, and the thermometer at 0, according to the above explained graduation, no corrections are necessary. But if, while the barometer continues at 27 inches, the thermometer should rise any number of degrees above 0, so many sixteenths of a line must be subtracted from the 27 inches, in order to obtain the true height of the barometer produced by the weight of

the atmosphere, and to reduce this observation to the state of the common temperature. On the other hand, if the thermometer should fall any number of degrees below 0, while the barometer remains at 27 inches, so many *sixteenths* must be added to that height in order to obtain the true altitude. These corrections are very simple and easy when the height of the barometer is at or near 27 inches. But if it fall several inches below this point, as the portable barometer frequently must, according to the stations in which it is placed for the purpose of measuring altitudes, the dilatations will no longer correspond with the degrees of heat, after the rate of $\frac{1}{16}$ th of a line for every degree of the thermometer; because the column of mercury being shortened, the quantity of fluid to be dilated must be diminished; and, according to a general statement, the quantity of dilatation for the same degree of heat will be as much diminished as the column is shortened. If, then, it should be still found convenient to reckon the dilatations by sixteenths of a line, these sixteenths must be counted on a scale, of which the degrees should be as much longer than the degrees of the first scale, as the shortened column of mercury is less than 27 inches, the height to which the length of the degrees of the first scale was adapted. E. G. Let the mercury descend, in consequence of the elevation of the barometer, to $13\frac{1}{2}$ inches, or half the mean column, and let the thermometer ascend ten degrees above the mean heat; then according to the rule $\frac{1}{16}$ ths should be deducted from the mean column for this temperature; but ten half-sixteenths only or $\frac{5}{8}$ ths must be subtracted from the column of $13\frac{1}{2}$ inches, because the sum of its dilatations will be half that of the former; the quantities of fluid being to one another in that proportion. As it would occasion considerable embarrassment to subdivide the sixteenths of correction into smaller fractions proportional to every half inch of descent in the barometer, the same end may be obtained in a much more easy manner by reckoning the corrections on different scales of the same length, with the degrees longer as the columns of the barometer are shorter. E. G. The degrees of correction on a scale applicable to the column of $13\frac{1}{2}$ inches will be double in length to those of the same degrees adapted to the column of 27 inches, and consequently the number of corrections will be reduced to likewise one half. M. de Lue constructed, in the manner which he has minutely described (*Recherches*, vol. ii. p. 26, &c.), on a piece of vellum, scales with these properties for no less than 23 columns of mercury, being all those between 28 inches and 29 inclusive, reckoning from half inch to half inch, within which extremes every practical case will be comprehended. This vellum he wrapped on a small hollow cylinder, including a spring, like a spring curtain, and he fixed it on the right side of the thermometer. The vellum was made to pass from right to left, behind the tube of the thermometer, and to move along its surface. The observer, in estimating the necessary corrections, draws out the vellum till the scale corresponding to the observed altitude of the barometer, touches the thermometer, and he counts them on that scale. The vellum is then let go, and it is gently furled up by the spring.

M. De Luc, having provided the necessary apparatus for the accurate mensuration of heights, proceeded to establish by experiment the altitudes corresponding to the different descents of the mercury; and he made choice of Saleve, a mountain near Geneva, about 3000 French feet high, for the scene of his operations. The height of this mountain was twice measured by levelling, and the result of the mensurations, at the interval of six months, gave a difference of only $10\frac{1}{2}$ inches. On this mountain he selected no less than 15 different stations, rising at the rate of nearly 200 feet one above another; and here he proposed to make such a number of observations as

would

would serve either to establish a new rule of proportion between the heights of places and the descents of the mercury, or to justify the preference of some one of those that had formerly discovered.

Soon after he had commenced his observations, an unexpected phenomenon occurred. Having observed the barometer, at one of the stations (*Recherches*, vol. ii. p. 49, &c.) twice in one day, he found the mercury higher in the second observation than in the first; and this variation he naturally ascribed to a change in the weight of the atmosphere, which must have affected his other barometer situated on the plain in the same manner. But he was not a little surprised when, on examining the state of the latter barometer, he found that it had pursued a contrary course, and that it had fallen while the other rose. As this difference could not proceed from any inaccuracy in the observations, it was so considerable as to discourage his progress and to disappoint his hope of success, unless he should be able to explore its cause, and to make due allowance for its effects. The experiment was carefully repeated at different periods. An observer on the mountain, and another on the plain, took their respective stations at the rising of the sun, and continued to make their respective observations, both of the barometer and thermometer, every quarter of an hour till the sun set. It was found, that the lower barometer gradually descended for the first three quarters of the day; after which it re-ascended, till in the evening it stood at nearly the same height as in the morning. But the higher barometer ascended for the first three quarters of the day, and then descended, so as to regain likewise about sun-set the altitude of the morning. The following theory seems to afford a satisfactory solution of this phenomenon. When the sun rises above the horizon of any place, his beams penetrate the whole section of the atmosphere of which that horizon is the base; but falling very obliquely on the greater part of it, they communicate little heat, and consequently produce little dilatation of its air. As the sun advances, his rays become more direct, and the heat and rarefaction of course increase. However, the greatest heat of the day is not felt when the sun is in the meridian and his rays are most direct, but it increases after mid-day while the place receives more heat than it loses; just as the tide attains not its highest altitude till the moon has proceeded a considerable way to the west of the meridian. Besides, the heat of the atmosphere is greatest at the surface of the earth, and seems not to ascend to any great distance above it; and therefore the dilatations of the air occasioned by the sun will be found principally, if not solely, near the earth. A motion of the adjacent air, in all directions, must take place in order to allow the heated air to expand itself. The heated columns, extending themselves vertically, will become longer, and also specifically lighter in consequence of the rarefaction of their inferior parts. As the motion of air, till it rises into wind, is not rapid, these lengthened columns will take some time to dissipate their summits among the adjacent less rarefied columns that are not so high; at least they will not do this as speedily as their length is increased by the rarefaction of their bases.

In order to apply this theory to the solution of the phenomenon above mentioned, it should be considered, that the barometer on the plain begins to fall a little after morning, because the column of air that supports it becomes specifically lighter on account of the rarefaction occasioned by the heat of the sun. It continues to fall during the three first quarters of the day, because the heat and consequent rarefaction are continually increasing. After this period it rises again, because the cold and condensation coming on,

the specific gravity is augmented by the rushing in of the adjacent air. Thus the equilibrium is restored, and the mercury returns to the altitude of the morning. The barometer on the eminence rises after morning, and continues so to do for three fourths of the day, for two reasons. The density of the columns of air is greatest near the earth, and decreases as the distance from it increases. The higher therefore we ascend in the atmosphere, we find air specifically lighter. But by the rarefaction of the base of the column that supports the mercury of the barometer on the eminence, the denser parts of that column are raised higher than they would naturally be if left to the operation of their own gravity. On this account, the higher barometer is pressed with a weight nearly as great as it would sustain, if it were brought down in the atmosphere to the natural place of that denser air now raised above it by the prolongation of the base of the column. The other reason is, that as the rarefaction does not take place at any great distance from the earth, little change is produced in the specific gravity of the portion of the column that presses on the higher barometer, and the summit of that column dissipates itself more slowly than it increases. Thus we see how this barometer must ascend during the first three fourths of the day, and pursue a course reverse of that on the plain. The condensations returning after this time, the denser air subsides, the equilibrium takes place, and the mercury descends to its first position.

This phenomenon suggested to M. De Luc (*Recherches*, vol. ii. p. 54, &c.) the idea of a second pair of thermometers, in order to measure the mean heat of the column of air intercepted between the barometers. These thermometers are extremely delicate and sensible, their tubes being the finest capillary, the glass very thin, and the diameters of the balls only three lines; the balls are insulated or detached from the scales, which are fixed to the tubes only by ligatures of fine brass wire covered with silk: by this contrivance the air has free access to the balls on all sides; and if the direct rays of the sun be intercepted at some distance by a scrap of paper or by the leaf of a tree, the thermometers will quickly mark the true temperature of the air. For the necessity and utility of these appendages to the author's apparatus, see the sequel of this article.

A new kind of *portable barometer* for measuring heights has been invented by Dr. J. A. Hamilton, and described in the *Transactions of the Royal Irish Academy* (vol. v. p. 95.). Instead of the leathern bag which confines the mercury in the common portable barometer, Dr. Hamilton substitutes a cylindrical cistern of ivory, about two inches long and upwards of one inch in diameter, with a screwed bottom and open top, somewhat contracted into a shoulder that receives internally a sound, clean and porous cork, about $\frac{3}{4}$ of an inch in length, and one in diameter, through which the glass tube is nicely inserted and pushed down midway. The construction depends upon this principle, that spongy cork affords a ready passage through its pores to the particles of air, but prevents the escape of quicksilver, unless a very powerful pressure be applied. Nevertheless, as it is not through the pores of that substance, but through the minute interstices between the cork and the inside of the ivory cylinder, that the air insinuates itself, some caution and experience are requisite to prevent the stopper from being fitted too tight: nor can the observer be always assured, that the confinement of the cork will occasion no inaccuracy in the results; for it will evidently require a considerable time, through the extremely slender communications, to restore the balance between the external and internal air, if ever that balance can rigorously obtain. Dr.

Hamilton gives very copious and circumstantial directions, together with an annexed engraving, for the construction, adjustment, and application of this instrument. AB (*fig. 96.*) represents a section of the barometer longitudinally, when put together and ready for use. F the ivory cylinder, CD the scale, with a vernier that slides so as to cover the aperture when the instrument is put by. E the attached thermometer in its case, and GG the brass caps that secure the ends. AB (*fig. 97.*) represents a section of the ivory cylinder with its cork C, and its tube T; SS is the surface of the mercury; M its mass; EE the shoulders that keep the cork C in its place; and FF is the bottom that screws in tight.

Dr. Hamilton remarks, that mercury is best cleansed by shaking it repeatedly in a phial with fresh portions of water; and the remark deserves attention. For correcting the errors of altitude caused by the fluctuation of the surface of the mercury in the basin, he recommends the computation of tables from the proportion which the aperture of the tube bears to that of the cylinder. His paper contains practical precepts for calculating heights from observations of the barometer, in a form adapted to practice; and he proposes to delineate vertical sections of a country, by means of a series of such observations, made during settled weather. In the same volume (p. 117, &c.) we have remarks and hints for the further improvement of barometers, by Dr. H. Hamilton, dean of Armagh, occasioned by the preceding communication. He observes, that the pores of cork may in time become choked with dust or moisture; and he therefore proposes, that instead of cork the box should have a top of ivory with a hole to drop in a floating gage, which might be occasionally stopped with a peg or serew, to render the instrument safely portable: or, which would be better, to have a cover serewed over the top of the box, and a hole in it corresponding with that in the box. When these two holes are connected, the box is open; and it is shut, when the holes are removed from each other by turning the cover and serewing it tight to the top of the box; and if there be a plate of soft leather between them, it will be sufficient to keep in the mercury when the instrument is agitated by carriage. The dean had a barometer made in this form, and found it to answer all the purposes of an open and of a portable one. Instead of making tables for correcting the error occasioned by the variation of the level of the mercury in the basin, he thinks it would be more convenient to contract proportionally the divisions of the scale. This obvious plan is illustrated at length. It is suggested, that these close barometers would serve just as well at sea as on land; and the hint merits attention, as a marine barometer is still an important desideratum.

Various improvements in the construction and use of the portable barometer, with its annexed apparatus, have been suggested by sir George Shuckburgh and Gen. Roy; and they have been adopted by several instrument makers in London. An instrument of this kind, possessing all the advantages of those by Mr. Ramsden and M. de Luc, and from its principle free from some inconveniences and error to which theirs is liable, is constructed by Mr. William Jones, an ingenious artist in Holborn. It is represented in (*Pl. XII. fig. 100.*) as inclosed in its mahogany case by means of three metallic rings, *b, b, b.* This case is in the form of a hollow cone divided into three arms or legs from *a* to *c*, and is so carved in the inside as to contain steadily the body of the barometer; and the arms, when separated, form three firm legs or supports for the barometer, when it is used for making observations. (See *fig. 101.*) The instrument is suspended at the part *g* of the case, by a kind of improved gimbals, and thus, by its own weight, it will be sufficiently

steadily when exposed to the weather. In that part of the frame where the barometer tube is visible, *ae*, there is a long slit or opening, so that the altitude of the mercury may be seen against the light, and the vernier piece *a* brought down to coincide with the edge of the mercury to the greatest possible exactness. When the instrument is placed on its support, the serew *f* is to be let down, that the mercury may subside to its proper height; and also a peg at *g* must be loosened, to give admission to the action of the external air upon the mercury contained in the box *b*. The adjustment, or mode of observing what is called the zero, or *c*, division of the column of mercury, is by means of a small floating ivory index or stem that rises up through the brass box from the cistern below in a hole made for that purpose. This will rise and shew itself directly under a small plate and serew fixed over as a cover, and is unscrewed to move upwards. With one eye even with the upper surface of the box, the hand at the regulating serew at the bottom of the frame must so turn the serew till the top of the index is very exactly even with the surface: thus will the adjustment for reading off be made after the stations. The vernier piece at *a* that determines the altitude of the column of mercury is to be brought down by the hand to a near contact, and then accurately adjusted by a small adjusting serew attached to the top of this vernier scale. This barometer has usually two different sorts of scales inserted on it: that on the right at *ae* is a scale of French inches from 19 to 31, measured from the surface or zero of the mercury in the box *b* below, divided into twelve parts or lines, and each line subdivided by the vernier into ten parts, so that the height of the column of mercury may be ascertained to the 120th part of a French inch. The scale which is on the other side, or the left of observation, is of the same length; but divided into English inches, each of which is subdivided into 20ths of an inch, and the vernier subdivides each 20th into 25 parts; so that the height of the mercury is thus ascertained to the 500th part of an English inch (viz. $20 \times 25 = 500$). But this vernier is figured double for the convenience of calculation: the first 5 divisions are marked 10, the 20 marked 40, and the 25 marked 50: then each exact division is reckoned as the two thousandths of an inch, which amounts to the same; for $\frac{2}{1000}$ is the same in value as $\frac{2}{1000}$ of an inch. A thermometer is always attached to the barometer, and indeed it is indispensably necessary: it is fastened to the body at *e*, counter sunk beneath the surface of the frame, which makes it less liable to be broken; the degrees of the thermometer arc marked on two scales, one on each side; viz. that of Fahrenheit and Reaumur, scales generally known; the freezing point of the former being at 32, and the latter at 0. On the right hand side of these scales there is a third, called a scale of correction: it is placed opposite to that of Fahrenheit, with the words *add* and *subtract*; and it serves as a necessary correction to the observed altitude of the mercury at any given temperature of the air shewn by the thermometer. There are several other valuable appendages to this instrument that cannot be distinctly represented in the figure: but its nature and use may be apprehended from the above statement. In complete observations, such as those to which we now refer, the observer should be provided with two barometers, or rather three, for fear of danger, and two or three separate thermometers. See the sequel of this article.

By very small additional contrivances this instrument may be rendered equally useful for making observations at sea with any marine barometer that has hitherto been invented.

The editor has been furnished with the following description

tion of the cistern, &c. of the portable barometer, according to the construction of Mr. Hawes, lately an eminent instrument-maker in London. A section of the cistern is represented in *Plate XII. of Pneumatics, fig. 102.* AAAABB is the cistern: the part AAAA, which contains the quicksilver, is made of wood, with a bottom of leather C, glued on the wooden ring DD, and pressed close against the wooden cylinder by means of the screw at EE, which screws on the brass cover or collar FF that covers the cylindrical cistern AA. This collar has a step at the top, as seen at G, to prevent its slipping, while it presses the ring DD against the wooden cylinder AA. When screwed tight, the quicksilver HH is prevented from escaping. II is part of the tube of the barometer, drawn nearly to a point, and covered with an ivory cap KK for defending it against injury. LL is a screw with a broad circular top Q, by means of which the leather C forces up the quicksilver so as to fill the tube, when the instrument is carried from one place to another. In order to prevent the oscillations of the quicksilver from breaking the tube by sudden jerks, a pin *a* with a head *b* passes through the screw LL; this pin has on the under side of the head a spiral spring to counteract the violence of a sudden motion. The two nuts M, N, are used to raise or depress the screw LL, and consequently the quicksilver; the proper height of which is indicated by the floating gage OO, the top of whose stem P corresponds to the top and outside of the cistern. When the barometer is not in use, the gage and aperture are covered by the plate *e*, which effectually confines the quicksilver, the under side of *e* being covered with leather. The lower end of the screw LL is slit up as high as *e*, and carries a cross pin *d* passing through the bottom of the pin *a b* to prevent it from rising too high. *Fig. 103.* represents a square frame to be screwed on the part BB *fig. 102*, and connected by wires from the angles to the legs as seen in the perspective view in *fig. 101.* This is used to prevent the barometer from vibrating.

The nonius is exhibited at large in *fig. 104.* A is a screw with a milled head tapped into the piece B, and allowed into and moveable in the piece C in the manner represented at D in *fig. 105.* which is a side view.

B and C in *fig. 106.* are horizontal sections of B and C, *fig. 104.* The spring *a* of the piece B is considerably stronger than that of C; so that it requires much greater force to make it slide up and down, whilst C, which slides very easily, is moved by turning the milled head E; and thus the lower surface of C is made to coincide with the upper surface of the mercury at F; and, besides, both the piece B and the nonius C may be depressed or raised at pleasure, as occasion requires, for a due adjustment of the nonius. Behind the plate *a b*, in the perspective view *fig. 101.* hangs a pendulum suspended at the point *a* which serves for setting the instrument vertical; and when it is brought into this position, a mark on the bob coincides with another on the plate, as seen at *b.* When the instrument is not in use, a fork connected with the screw *e* is pushed up, and prevents the pendulum from shaking.

In order to adapt the portable barometer more completely to the purpose of measuring heights, in which use of it peculiar accuracy of observation is necessary, it should be furnished with two microscopes or magnifying glasses, one of which should be placed at the beginning of the scale; and either this should be moveable, so that it may always be brought to the surface of the mercury in the cistern, or the cistern should be so contrived that its surface may always be brought to the beginning of the scale. By this glass the coincidence may be accurately perceived. The other microscope must be moveable, so as to be set opposite to the surface of

the mercury in the tube; and the scale should be furnished with a vernier, which divides an inch into 1000 parts, and constructed of materials, the expansion of which is precisely ascertained. For an account of many ingenious contrivances to make the barometer accurate, portable, and commodious, the reader may consult Magellan's "Diff. de Diverses Instr. de Phys." *Phil. Trans.* vol. lxvi. vol. lxviii. *Journ. de Phys.* xvi. 302. xviii. 391. xix. 328. 326. xvi. 476. xvii. 390. Sulzer, *Act. Helvet.* iii. 259. De Luc, *Recherches, &c.* ubi supra. Cardin. de Luynes, *Mem. Par.* 1768. Van Swinden's *Positiones Physicæ. Com. Acad. Petrop.* i. Id. Nov. ii. 200. viii.

Mr. Magellan, in his edition of "Cronstedt's Mineralogy," has shewn that great errors may arise in barometrical measurements for want of due attention to the specific gravity of the mercury with which barometers are filled. If two barometers, each 30 inches high, and in every other respect similarly circumstanced, be filled with mercury of different specific gravities, that of the one being 13,62, and that of the other 13,45, the error in the result would be no less than 327 feet; because the heights of the mercurial columns in each barometer must be in the inverse ratio of their specific gravities; viz. 13,45 : 13,62 :: 30 : 30,379. But the logarithm of 30 is 4771,21, and that of 30,379 is 4825,73, neglecting the indices, and their difference is 54,52, which shews that there is a difference of 54,52 fathoms or 327 feet in the altitudes of the two places, where the barometers should have been stationed, though in reality they were on the same level. But if the specific gravity of the mercury in the two barometers were according to the different statements of Bergman and Fourcroy, the one 14,110 and the other 13,000, (and this may happen to be the case, as the heaviest is commonly reputed to be the purest mercury.) the error must have amounted to 355,76 toises, or 2134½ feet, because 13,000 : 14,110 :: 30 : 32,561. But the logarithm of 30 is 4771,21, and that of 32,561 is 5126,97, and the difference, or 355,76, shews that the error should amount to so many fathoms, or 2134½ feet. See the sequel of this article.

BAROMETER, Phenomena of the. These are the variations of height in its mercurial column, for ascertaining which many contrivances in the structure of the barometer have been proposed; the principal of which have been detailed in the preceding articles; and the subject will be further pursued in the sequel. The uses to which these phenomena have been subservient, are the prediction of the weather from the variable weight of the atmosphere, indicated by the rise and fall of the mercury in the barometer, and the measurement of altitudes, to which they have been lately applied with singular assiduity and success.

The phenomena of the barometer, considered as a "weather glass," have been very differently stated and explained by various writers; and they are so precarious, that it is extremely difficult to form any fixed and general rules concerning them. Although we have reason to believe, that the barometer never fails to indicate a storm, or any very great change of weather, for some hours before it occurs; yet its variations afford no indications or prognostics that are absolutely certain, with respect to those less considerable changes to which the weather is subject in our variable climate. With certain restrictions, they afford some ground for probable conjecture; and these restrictions are to be determined merely by the sagacity of long-continued observation and experience. Strictly speaking, the height of the mercury in the barometer hath no immediate and necessary connection either with rain or fair weather. That its variable height is the immediate consequence of the variable

variable pressure of the atmosphere, is a fact that admits of no doubt; but the causes of this variable pressure have not yet been fully and satisfactorily ascertained; and how far the state of the weather, in all its minute and sudden changes, depends upon it, is a question that still remains to be determined. M. Pascal was one of the first persons who particularly observed the variations of the barometer, and referred them to corresponding changes in the weight of the air; but he acknowledges, that it is very difficult to explain both the one and the other, as well as the connection that subsists between them. He observes, in general, that the mercury is commonly highest in winter and lowest in summer; that it is least variable at the solstices, and most variable at the equinoxes: and he adds, in direct contradiction to later experience, that the mercury usually falls in fine weather, and that it rises when the weather becomes cold or the air is loaded with vapours. M. Pascal was followed by Perrier, Beal, Wallis, Garcin, Garden, Litter, Halley, Gerßen, De la Hire, Mariotte, Le Cat, Woodward, Leibnitz, De Mairan, Bernouilli, Muschenbroek, &c.; all of whom have given different solutions of the phenomena of the barometer.

The principal observations, that have been made on the variations of this instrument, are summed up by Mr. Kirwan (Irish Transf. vol. ii. p. 46, &c.) in the following particulars.

I. The more considerable elevations and depressions of the mercury in the barometer happen at a very short interval of time in places very remote from each other. This correspondence was observed by Mr. Derham in 1699 between the heights of the mercury at Upminster in Essex and Townley in Lancashire; and afterwards by Mr. Maraldi between the variations at Paris and Genoa, at the distance of nearly four degrees of latitude, who adds, during these variations different winds prevailed at these places. But Mr. Kirwan observes, that where there is a considerable difference of longitude, the like agreement is not found.

II. The deviations of the mercury from its mean annual altitude are far more frequent and extensive in the neighbourhood of the poles than in that of the equator. At Petersburg, in 1725, the mercury once stood at the stupendous height of 31,59 inches, if we may credit Mr. Consett; and yet it has been seen so low as 28,14 inches. In the northern parts of France the variations are greater than in the southern: at Naples they scarcely exceed one inch. In Peru, under the equator, and at the level of the sea, they amount only to two or three tenths of an inch; but in other parts, within a few degrees of the line, on the approach of the rainy season or of hurricanes, the barometer falls an inch or more.

III. The variations without the tropics are greater and more frequent in the winter than in the summer months.

IV. The variations are considerably smaller in very elevated situations than on the level of the sea. Thus M. Bouguer observed, that on the coasts of Peru the variations extended to $\frac{1}{2}$ of an inch: at Quito, elevated 9374 feet above the sea, they comprehended only 0,083 of an inch. M. Saussure made similar observations in Savoy, as did Mr. Lambert in Switzerland.

V. The mean height of the barometer on the level of the sea in most parts of the globe hitherto examined, is about 30 inches. M. Bouguer, under the line, observed it at 29,908 inches; but as his barometer was not purged of air by fire, it stood lower than it should have done. Sir George Shuckburgh (Phil. Transf. vol. lxxvii. p. 586.), on a mean of several observations on the coasts of Italy and England,

found it at 30,04, when the temperature of the mercury was 55°, and that of the air 62°. The mean height of the barometer in London, upon an average of two observations in every day of the year, kept at the house of the Royal Society, for many years past, is 29,88; the mean temperature or height of the thermometer, according to the same, being 58°. The greatest height observed by sir G. Shuckburgh, Dec. 26, 1778, in London, was 30,948 inches, the thermometer being at 47°; and reduced to the heat of 50°, it was 30,957: and this, he says (Phil. Transf. vol. lxxix. p. 370.), is the greatest height, which, as far as he has been able to collect, it has ever been seen to stand at in any country, where observations have been made and recorded, since the first invention of this instrument. In the proximity of the poles, says Mr. Kirwan, the annual mean heights of the barometer differ much more from the above standard than in the more southern parts of our hemisphere.

In estimating the connection of the variations of the barometer with the weather, Dr. Halley has proposed the following rules:

I. In calm weather, when the air is inclined to rain, the mercury is commonly low.

II. In serene and settled weather, and also in calm and frosty weather, the mercury is generally high.

III. Upon very high winds, though not accompanied with rain, the mercury sinks lowest, regard being had to the point of the compass from which the wind blows.

IV. The greatest heights of the mercury are found upon easterly and north-easterly winds, other circumstances being alike: to which it may be added, that under a southerly wind it is commonly low. The above four observations, made by Dr. Halley in England, seem to be most universal, as they were found by Mr. Melander (Schwed. Abhandl. 1773, S. 255) to apply to lat. 39°, and by M. de Luc to lat. 46°.

V. After very great storms of wind, when the mercury has been very low, it generally rises again very fast.

VI. The more northerly places have greater alterations of the barometer than the more southerly.

VII. Within the tropics, and near them, there is little or no variation of the mercury in all weathers. At St. Helena it is little or nothing; at Jamaica $\frac{2}{5}$ ths of an inch; whereas in England it amounts to 2 $\frac{1}{2}$ inches, and at Petersburg to 3 $\frac{1}{2}$ nearly.

Dr. Beal, who adopted the opinion of M. Pascal, observes, that, *ceteris paribus*, the mercury is higher in cold weather than in warm; and usually in the morning and evening higher than at mid-day: that, in settled and fair weather, it is higher than either a little before or after or in the rain; and that it generally descends lower after rain than it was before it. And he ascribes these effects to the vapours with which the air is charged in the former case, and which are dispersed by the falling rain in the latter. If it chance to rise higher after rain, it is generally followed by a settled serenity. He adds, that there are frequently great changes in the air, without any settled alteration in the barometer.

An ingenious author observes, in relation to this use of barometers, that, by their means, we may regain the knowledge, which still resides in brutes, and which we have forfeited by not continuing in the open air as they generally do, and by our intemperance corrupting the crasis of our organs of sense.

Mr. Patrick's rules for judging of the weather by the rise and fall of the mercury in the barometer, have been much approved, and are to be accounted for on the same principles with those of Dr. Halley. They are as follow:—1. The rising of the mercury presages, in general, fair weather;

and

and its falling, foul weather; as rain, snow, high winds, and storms.

2. In very hot weather, the fall of the mercury indicates thunder.

3. In winter, the rising presages frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw: but in continued frost, if the mercury rises, it will certainly snow.

4. When foul weather happens soon after the falling of the mercury, expect but little of it: and, on the contrary, expect but little fair weather when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes; then expect a great deal of wet, and probably high winds.

7. The unsettled motion of the mercury, denotes uncertain and changeable weather.

8. You are not so strictly to observe the words engraved on the plates (though for the most part it will agree with them), as the mercury's rising and falling; for if it stands at much rain, and then rises up to changeable, it presages fair weather, although not to continue so long as it would have done, if the mercury were higher: and so, on the contrary, if the mercury stood at fair, and falls to changeable, it presages foul weather, though not so much of it, as if it had sunk down lower.

From these observations it appears, says Mr. Rowning (Nat. Philos. part ii. diff. 4.), that it is not so much the height of the mercury in the tube that indicates the weather, as the motion of it up and down: wherefore, in order to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is exactly rising or falling, to which end the following rules are of use:

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising.

2. If the surface of the mercury is concave, or hollow in the middle, it is sinking. And,

3. If it is plain or level, or rather if it is a little convex, the mercury is stationary; for mercury being put into a glass tube, especially a small one, will naturally have its surface a little convex; because the particles of mercury attract each other more forcibly than they are attracted by glass. Farther,

4. If the glass be small, shake the tube; and if the air be growing heavier, the mercury will rise about half the tenth of an inch higher than it stood before; if it is growing lighter, it will sink so much. This proceeds from the mercury sticking to the sides of the tube, which prevents the free motion of it, until it is disengaged by the shock. Therefore, when an observation is to be made by such a tube, it ought always to be shaken first; for sometimes the mercury will not vary of its own accord, until the weather it ought to have indicated be present.

To the preceding rules we may subjoin the following, deduced from later and more accurate observation of the motions of the barometer, and the consequent changes in the air of this country:

1. In winter, spring, and autumn, the sudden falling of the mercury, through a large interval, denotes high winds and storms; but in summer it denotes heavy showers, and often thunder; and it always sinks lowest of all for great

winds, though not accompanied with rain; though, however, it falls more for wind and rain together, than for either of them alone. Also, if, after rain, the wind change into any part of the north, with a clear and dry sky, and the mercury rise, it is a certain sign of fair weather.

2. After very great storms of wind, when the mercury has been low, it commonly rises again very fast. In settled fair and dry weather, except the barometer sink much, expect but little rain; for its small sinking then is only for a little wind, or a few drops of rain; and the mercury soon rises again to its former station. In a wet season, suppose in hay-time and harvest, the smallest sinking of the mercury must be regarded; for when the constitution of the air is much inclined to showers, a little sinking in the barometer then denotes more rain, as it never at this time stands very high. And if, in such a season, it rise suddenly, very fast, and high, expect not fair weather more than a day or two, but rather that the mercury will fall again very soon, and rain immediately follow. The slow gradual rising, and keeping on to do so for two or three days, are most to be depended upon for a week's fair weather; and the unsettled state of the quicksilver always denotes uncertain and changeable weather, especially when the mercury stands any where about the word *changeable* on the scale.

3. The greatest heights of the mercury, in this country, are found upon easterly and north-easterly winds; and it may often rain or snow, the wind being in these points, and the barometer may sink but little or not at all, or it may even be in a rising state, the effect of those winds counteracting. But the mercury sinks for wind, as well as for rain, in all the other points of the compass; but rises as the wind shifts about to the north or east, or between those points: but if the barometer should sink with the wind in that quarter, expect it soon to change from thence; or else, if the fall of the mercury should be considerable, a heavy rain is likely to ensue, as it sometimes happens.

BAROMETER, Cause of the Phenomena of the. Those which have been enumerated, are the chief phenomena of the barometer; to account for which, the hypotheses that have been framed are almost innumerable. It would far exceed our limits to detail them all; we must content ourselves with briefly reciting some of the principal, and refer the reader who is desirous of farther information to De Luc's "Recherches," vol. i. ch. iii.

Some, as Pascal, Beal, Wallis, and Garcin, have accounted for the change in the weight of the air by the augmentation of the atmosphere in consequence of the introduction of vapours, and its diminution by their fall; others, as Perrier, Garden, Le Cat, and De Mairan, have ascribed it to the variations of heat; and others, as Gaiden, to the alterations of the specific gravity of the air; and Dr. Halley refers it to the accumulation or dispersion of the air by contrary winds. Wallis, Halley, and De Mairan have supposed that there is a difference in the vertical pressure of the air, when in motion and at rest. Wallis, and some other philosophers, have conceived that the height of the barometer depends upon the variations that occur in the elasticity of the air, and that it is directly proportional to these variations. Some have also had recourse to the contractions and dilatations of the mercury itself, as Wallis and Lister; others, as Gersten, suppose vibrations produced in the particles of air by the winds. De la Hire and De Mairan imagine that air is removed from the south to the north, and from the north to the south: Mariotte supposes that the inclination of the winds to the surface of the earth is sometimes greater and sometimes less. Woodward and Hamberger conceive that there is a shock of vapours against the air, when they rise, and that this ceases when they are at rest. Leibnitz supposes

poses that there is a diminution in the weight of the air when rain falls; and De Mairan apprehends, that an agitation of the air is occasioned by vapours; and Bernoulli is of opinion, that an augmentation of the atmosphere is produced by a dilatation and discharge of the air inclosed within the bowels of the earth, and that there is a diminution of it when the contrary happens. To these several causes acting separately or conjointly, and to several circumstances attending their different operation, the variations of the barometer have been attributed. But these causes may all be reduced to three general classes: viz. variations of temperature; the velocity and other qualities of different winds; and the agency of vapour.

Dr. Lister accounts for the changes in the barometer from the alterations of heat and cold. This, he says, he has often observed, that in storms, &c. when the mercury is at the lowest, it breaks, and emits small particles, which he calls a kind of fretting; and argues, that in all times of its descent, it is more or less on the fret. In this disorder, he thinks, its parts are contracted, and brought closer together; and, for that reason, descend; besides, in the fretting they let go little particles of air, before inclosed in them, and these rising into the top of the tube, the mercury must sink, both from the column's being shortened by their escape, and by their lying upon it. Mercury therefore, he adds, rises either in very hot or very cold weather, between the tropics, &c. as being then in its natural state; and again, in the intermediate degrees of heat and cold it falls, as being contracted, and as it were convulsed, and drawn together. Phil. Trans. N^o 165. But his account, however ingenious, yet comes far short of accounting for the phenomena; nay, in some respects it contradicts them.

The changes in the weight of the atmosphere, therefore, must be laid down as the cause of those in the barometer; but then, the cause of that cause, or whence those alterations arise in the atmosphere, it will be no easy matter to determine; there being, perhaps, no one principle in nature that will account for such a variety of appearances, and those too so irregular. It is probable the winds, as driven this or that way, have a great share in them; some share too, vapours and exhalations, rising from the earth, may have; some, the changes in the air of the neighbouring regions; and some, the flux and reflux occasioned in the air by the moon; and also some chemical causes operating between the different particles of matter.

Dr. Halley thinks the winds and exhalations sufficient; and, on this ground, gives us a rationale of the barometer. The substance of what may be said on that head, is as follows:

1st, then, The winds must necessarily alter the weight of the air in any particular country; and that, either by bringing together and accumulating a greater quantity of air, and so loading the atmosphere of any place; which will be the case, as often as two winds blow at the same time, from opposite points towards the same point: or by sweeping away a part of the air, and removing some of the load, and thus giving room for the atmosphere to expand itself; which will be the case when two winds blow at the same time, and from the same point, opposite ways: or lastly, by cutting off the perpendicular pressure of the atmosphere; which happens as often as any single wind blows briskly any way; it being found, by experiment, that a strong blast of wind, even made by art, will render the atmosphere lighter; and accordingly, the mercury, in a tube under which it passes, as well as in another at a distance from it, will subside considerably. See Phil. Trans. N^o 292.

2^{dly}, The cold nitrous particles, and even air itself condensed in the northern parts, and driven elsewhere, must load the atmosphere, and increase its pressure.

3^{dly}, Heavy dry exhalations from the earth must increase the weight of the atmosphere, and heighten its elastic force, as we find the specific gravity of menstruums increased by dissolved salts and metals.

4^{thly}, The air being rendered heavier from these and the like causes, is thereby the more able to support the vapours; which being likewise intimately mixed with it, and swimming every where equally through it, make the weather serene and fair: again, the air being made lighter, from the contrary causes, it becomes unable to support the vapours wherewith it is replete; these, therefore, precipitating, are gathered into clouds; and those, in their progress, coalesce into drops of rain.

These things observed, it appears pretty evident, that the same causes which increase the weight of the air, and make it more able to support the mercury in the barometer, do likewise occasion a serene sky, and a dry season; and the same causes which render the air lighter, and less able to support the mercury, do likewise generate clouds and rain. Hence, 1st, When the air is lightest, and the mercury in the barometer is lowest, the clouds are very low, and move swiftly; and when, after rain, the clouds break, and a calm sky again shines forth, being purged of the vapours, it appears exceedingly bright and transparent, and affords an easy prospect of remote objects.

2^{dly}, When the air is heavier, and the mercury stands higher in the tube, the weather is calm, though somewhat less clear, because the vapours are dispersed every where equally; if any clouds now appear, they are very high, and move slowly; and when the air is heaviest of all, the earth is frequently found enveloped in pretty thick clouds, which appear to be formed out of the grosser exhalations, and which the air is then able to sustain, though a lighter atmosphere could not.

3^{dly}, Hence it is, that with us the mercury stands highest in the coldest seasons, and when the wind blows from the north or north-east corner: for, in that case, there are two winds blowing towards us at the same time, and from opposite corners; there being a constant west wind found in the Atlantic ocean, at the latitude corresponding to our's. To which we may add, that in a north wind, the cold condensed air of the northern parts is brought hither.

4^{thly}, Hence, in the northern regions, the variation of the mercury is more sensible than in the southern ones; the winds being found more strong, more frequent, more various, and more opposite to each other in the former, than in the latter.

Lastly, Hence it is, that between the tropics, the variation of the mercury is scarcely sensible; the winds there being extremely gentle, and usually blowing the same way.

But this account, however well adapted to many of the particular cases of the barometer, seems to come short of some of the principal and most obvious ones: and is, besides, liable to several objections.

For, 1st, If the wind were the sole agent in effecting these alterations, we should have no alterations without a sensible wind, nor any wind without some alteration of the mercury: both which are contrary to experience.

2^{dly}, If two winds be supposed blowing from the same place, viz. London, opposite ways, viz. N.E. and S.W. there will be two others, blowing from opposite points, viz. N.W. and S.E. to the same place; which two last will balance the first, and bring as much air towards the point, as the others swept from it. Or thus, in proportion as the air

is carried off N.E. and S.W. the adjacent air will crowd in from the other points, and form a couple of new currents in the direction N.W. and S.E. to fill up the vacancy, and restore the equilibrium. This is a necessary consequence from the laws of fluids.

3dly, If the wind were the sole agent, the alterations in the height of the mercury would only be relative, or topical; there would be still the same quantity supported at several places taken collectively: thus, what a tube at London lost, another at Paris, or at Pisa, or at Zurich, &c. would at the same time gain. But we find the very contrary true in fact; for from all the observations hitherto made, the barometers in several parts of the globe rise and fall together; so that it must be some alteration in the absolute weight of the atmosphere that accounts for the rise and fall of the mercury.

Lastly, Setting aside all objections, these popular phenomena, the mercury's fall before, and rise after rain, seem to be inexplicable on the ground of this hypothesis: for suppose two contrary winds sweeping the air from over London, we know that few, if any, of the winds reach above a mile high; all, therefore, they can do, will be to cut off a certain part of the column of air over London: if the consequence of this be the fall of the mercury, yet there is no apparent reason for the rain's following it. The vapours indeed may be let lower, but it will only be till they come into an air of the same specific gravity with themselves; and there they will be suspended as before.

M. Leibnitz, about the year 1710, in a letter written to the abbé Bignon, endeavoured to supply the defects of this hypothesis with a new one of his own. The new principle, upon which Leibnitz's hypothesis is founded, was illustrated by M. Fontenelle in the History of the Royal Academy of Sciences at Paris for the year 1711. He asserts, that a body immersed in a fluid only weighs with that fluid while it is sustained by it; so that when it ceases to be sustained, i. e. when let fall, its weight ceases to make a part of that of the fluid, which by this means becomes lighter. Thus, adds he, the watery vapours, while sustained in the air, increase its weight; but when let fall, they cease to weigh along with it. Thus the weight of the air is diminished; and thus the mercury falls, and rain ensues.

But M. Leibnitz's principle, notwithstanding the experiment he brings to confirm it, is false, as has been evidently made appear by a counter experiment of Dr. Defaguliers. (See his Course of Exp. Philos. vol. i. p. 282, &c.) For a body, whether specifically equal or lighter or heavier than a fluid, while it is immersed in it, whether it be at rest, or in motion, adds to the fluid a weight equivalent to that of an equal bulk of the fluid; as follows from that law in hydrostatics, that fluids gravitate according to their perpendicular altitudes. However, were M. Leibnitz's principle true, yet it is defective; and that in the same respect with Dr. Halley's; nor would it account for the phenomena more than the other. For, supposing the vapours by being condensed, to be put in a motion downwards, and so ceasing to gravitate with the atmosphere; they will therefore fall, till they reach a part of the atmosphere of the same specific gravity with themselves; and there they will hang as before. If the mercury fall, it will only be during the time of that descent; for these once fixed, the former gravity is retrieved; or, were it not retrieved, yet no rain would succeed the fall of the mercury.

The hypothesis, proposed by Mr. Chambers, is somewhat similar to that of Leibnitz, and liable to the same objection. It is as follows: suppose any number of watery vesicles floating in any part of the atmosphere,

over any determinate portion of the globe; if the upper vesicles be condensed by the cold of the superior regions, their specific gravity will be increased, and they will descend; where meeting with other vesicles not yet precipitated, they will coalesce, or run into larger vesicles, by the known laws of attraction. Or, if we rather chuse to have the wind act, let it drive either horizontally or obliquely, some vesicles will be driven against others; by which means likewise will the particles coalesce, and form new and larger vesicles as before; so that their number, which before was, suppose a million, will now be reduced, v. gr. to a hundred thousand.

But by the same coalition whereby their number is diminished, their specific gravity, if we may so call it, is increased, i. e. they come to have more matter in the same space, or under an equal surface; as may be easily proved from principles of geometry: for in augmenting the mass of any homogeneous body, the increase of surface does not keep pace with that of the solidity; but that of the former is as the square of the diameter, and that of the latter as the cube of the same.

But since the same quantity of matter is now in a less space or under less dimensions, it will lose less of its weight by the resistance of the medium. This is evident; for a body immersed in a fluid loses nothing of its weight but by the friction of its parts against those of the fluid; but the friction is evidently as the surface; therefore, when the surface is lessened, the resistance must be so too. Consequently, the vesicles, whose gravity before the coalition was equal to the resistance of the medium, now that resistance is diminished, will descend; and that with a velocity in the ratio of the increase of the mass to the increase of the surface.

In their descent, as they arrive at denser parts of the atmosphere, their mass and surface again will be increased by new coalitions; and thus, by constant fresh accessions, more than equal to the constant resistances, they will be enabled to pursue their journey through all the stages of the air, till they reach the earth; their masses exceedingly magnified, and in the form of rain.

Now that the vapours have got down, let us consider how the barometer must have been affected during their passage.

Before any of the vesicles began to subside, either from the action of the cold, or of the wind, they all floated in a certain portion of the atmosphere, and all gravitated towards the centre. Here now, each respectively residing in a part of the medium of the same specific gravity with itself, will lose as much of its weight as is equal to that of a part of the medium of the same bulk with itself, i. e. each will lose all its weight. But then, whatever weight each loses, it communicates to the medium, which now presses on the surface of the earth with its own weight and that of the vesicles conjointly. Suppose then this united pressure keeps up the mercury in the barometer at thirty inches; by the coalition of the vesicles from the causes aforesaid, their surfaces, and consequently their friction, are lessened; therefore, they will communicate less of their weight to the air, i. e. less than the whole; and consequently they will descend with the excess, i. e. with a velocity equal to the remainder, as before observed. Now, as the vesicles can act no otherwise on the surface of the earth but by the mediation of the interjacent air, in proportion as their action on the medium is less, their action on the earth will be less. It is also evident, that the surface of the earth must be now less pressed than before; and that in proportion as the vesicles reserve more of their weight uncommunicated to the medium, to promote their own descent, i. e. in proportion to the velocity of the falling vesicles; which is

again in proportion to their bulks. Thus, as the vesicles descend, the bulks continually increasing, the friction, and therefore the pressure on the earth, and lastly the height of the mercury, will continually decrease, during the whole time of the fall.—Hence we see, both why the vesicles, when once beginning to fall, persevere; why the mercury begins to fall at the same time; and why it continues and ceases to fall together with them; which were the great desiderata in the philosophy of the barometer.

There is one objection that evidently lies against this theory, viz. that the vesicles being put in motion, and striking against the particles of the medium and one another with some moment, will meet with a considerable resistance from the *vis inertia* thereof; by which means their descent will be retarded, and the pressure of the atmosphere retrieved; the impetus of the moving vesicles being supposed to compensate for their loss of surface. Thus a heavy body sustained in a fluid by a hair, and moved up and down therein, presses more on the bottom than when held at rest; which additional pressure will be the greater as the velocity of the falling vesicles is greater; a greater impulse being required to break through the *vis inertia* of the contiguous particles in a less time than in a larger.

But it is alleged, that we have both reason and experiment against this objection; for the velocity of the vesicles, in these circumstances, must necessarily be very small, and their impulse inconsiderable; besides, the *vis inertia* of the air must be exceedingly weak, by reason of its extreme subtilty; and it must be a very improper vehicle to convey an impulse to a distance by reason of its elasticity; we also find that a piece of lead, which is a ponderous body, falling with great moment, gravitates considerably less, in its descent through water, which is a gross unelastic medium, than when sustained at rest therein; in which the several experiments of Reaumur, Ramazzini, and Defagniers, all agree.

M. de Luc (Recherches, &c. vol. i. p. 138.) supposes that the changes observed in the weight of the atmosphere are principally produced by the presence or absence of vapours floating in it. Others have attributed the effect to vapours, but have given a different explication of it. It is his opinion, that vapours diminish the specific gravity, and consequently the absolute weight of those columns of the atmosphere into which they are received, which, notwithstanding this admixture, remain of an equal height with the adjoining columns that consist of pure or dry air. He afterwards more largely explains and vindicates this theory, and applies it to the solution of the principal phenomena of the barometer, connected with or produced by the varying density and weight of the atmosphere.

Dr. James Hutton, in his "Theory of Rain" (see RAIN), printed in the Edinburgh Transactions, vol. i. p. 41, &c. suggests several plausible reasons in favour of his opinion, that the diminution of the weight of the atmosphere by the fall of rain is not the cause of the fall of the barometer; but that the principal, if not the only cause, is to be sought for in the commotions of the atmosphere that are chiefly produced by sudden changes of heat and cold in the air. "The barometer," he says (p. 78.), is an instrument necessarily connected with motions in the atmosphere; but it is not equally affected with every motion in that fluid body. The barometer is chiefly affected by those motions by which there are produced accumulations and abstractions of this fluid, in places or regions of sufficient extent to affect the pressure of the atmosphere upon the surface of the earth. But as every commotion in the atmosphere may, under proper conditions, be a cause for rain, and as the want of commotion in the atmosphere is naturally a cause of fair

weather, this instrument may be made of great importance for the purpose of meteorological observations, although not in the certain and more simple manner in which it has been, with the increase of science, so successfully applied to the measuring of heights."

In the "Encyclopædia Britannica," art. BAROMETER, we have another theory of changes in the barometer, as depending on the heat in the atmosphere, not as producing commotions in it, but as altering the specific gravity of the air by the variations of heat and cold. The preliminaries to this hypothesis are: 1st. That vapour is formed by an intimate union between the elements of fire and water, in consequence of which the fire or heat is so totally enveloped, and its action so entirely suspended by the watery particles, that it not only loses its properties of burning and of giving light, but becomes incapable of affecting the most sensible barometer, in which case, it is said by Dr. Black, the author of this theory, to be in a latent state. 2dly. If the atmosphere be affected by any unusual degree of heat, it thence becomes incapable of supporting so long a column of mercury as before, for which reason the barometer sinks.

From these primary principles or axioms it is inferred, that as vapour is formed by an union of fire with water, whether by an elective attraction or a solution of the water in the fire, the vapour cannot be condensed till this union, attraction, or solution be at an end. Hence it follows that the commencement of the condensation of the vapour, or the first signs of approaching rain, must be the separation of the fire which is latent in the vapour. This may at first be slow and partial, or it may be sudden and violent; in the first case the rain will come on slowly, and after a considerable interval; in the other it will come on very quickly and in a great quantity. But Dr. Black has proved, that when fire quits its latent state, however long it may have lain dormant and insensible, it always re-assumes its proper qualities, and affects the thermometer as if it had never been absorbed. The consequence of this must be, that in proportion as the latent heat is discharged from the vapour, those parts of the atmosphere into which it is discharged, will be sensibly affected by it; and in proportion to the heat communicated to those parts, they will become specifically lighter, and of course the mercury will sink. When the separation between the fire and water is gradual and slow, the barometer may indicate rain for a considerable time before it happens; or if the sensible heat should be absorbed by the colder parts of the atmosphere, or by any means be prevented from affecting the specific gravity of the air, the barometer will not be affected; and yet the water, deprived of the heat that is necessary for sustaining it, must descend in rain; and hence it happens, that the indications of the barometer are not always just. Hence it also appears, that though the specific gravity of the air is diminished, unless this diminution proceeds from a discharge of the latent heat contained in the vapours, no rain will follow; and thus the sinking of the barometer may prognosticate wind as well as rain, or sometimes no change at all. The great descent of the mercury in the barometer between the tropics in the time of hurricanes, noticed by Dr. Halley, is ascribed, as to its probable cause, to a great commotion in the electric fluid, by which the air is internally agitated, and its gravitation in part suspended.

In the fourth volume of the "Memoirs of the Literary Society of Manchester," we have a curious paper on this subject, viz. "Meteorological Observations made on different parts of the Western Coast of Great Britain;" arranged by T. Garnett, M. D. The materials of this paper were furnished by several observers; but those of Mr.

Copland,

Copland, surgeon at Dumfries, are of peculiar importance. This gentleman is of opinion that the changes of the barometer indicate approaching cold and hot weather, with much greater certainty than dry and wet. "Every remarkable elevation of the barometer, he says, when it is of any duration, is followed by very warm or dry weather, and moderate as to wind, or by all of them; but heat seems to have most influence and connection; and when it is deficient, the continuance of the other two will be longer and more remarkable; therefore the calculation must be in a compound ratio of the excess and deficiency of the heat, and of the dryness of the weather in comparison of the medium of the season; and with regard to the want of strong wind, it appears to be intimately connected with the last, as they shew that no precipitation is going on in any of the neighbouring regions."

In his 14th and 15th remarks, he had said,

'14th, That the barometer being lower, and continuing so longer than what can be accounted for by immediate falls, or stormy weather, indicates the approach of very cold weather for the season; and also, cold weather, though dry, is always accompanied by a low barometer, till near its termination.'

'15th, That warm weather is always preceded and mostly accompanied by a high barometer; and the rising of the barometer in the time of broken or cold weather, is a sign of the approach of warmer weather: and also if the wind is in any of the cold points, a sudden rise of the barometer indicates the approach of a southerly wind, which in winter generally brings rain with it.'

In the two following remarks, Mr. Copland had explained certain phenomena from a principle similar to that on which Dr. Darwin has so much insisted. (Botanic Garden, I. notes p. 79, &c.)

'That the falling of the barometer may proceed from a decomposition of the atmosphere occurring around or near that part of the globe where we are placed, which will occasion the electricity of the atmosphere to be repelled upwards in fine lambent portions; or driven downwards or upwards in more compacted balls of fire; or lastly, to be carried along with the rain, &c. in an imperceptible manner to the surface of the earth; the precipitation of the watery parts generally very soon takes place, which diminishes the real gravity of the atmosphere, and also by the decomposition of some of the more active parts, the air loses part of that elastic and repulsive power which it so eminently possessed, and will therefore press with less force on the mercury of the barometer than before, by which means a fall ensues.

'That the cause of the currents of air or winds, may also be this way accounted for: and in very severe storms, where great decompositions of the atmosphere take place, this is particularly evident, such as generally occur in one or more of the West India islands at one time, a great loss of real gravity, together with a considerable diminution of the spring of the air immediately ensues; hence a current commences, first in that direction whence the air has most gravity, or is most disposed to undergo such a change; but it being soon relieved of its superior weight or spring on that side, by the decomposition going on as fast as the wind arrives in the island, it immediately veers to another point, which then rushes in mostly with an increase of force; thus it goes on till it has blown more than half way round the points of the compass during the continuation of the hurricane. For in this manner the West India phenomena, as well as the alteration of the wind during heavy rains in this country, can only be properly accounted for.' See remark No. 4.

Mr. C's 4th aphorism is, 'That the heaviest rains, when of long continuance, generally begin with the wind blowing easterly, when it gradually veers round to the south; and that the rain does not then begin to cease till the wind has got to the west, or rather a little to the northward of it, when, it may be added, it commonly blows with some violence.'

Mr. Kirwan, in an elaborate paper on this subject (see Irish Transactions, vol. ii. p. 49, &c.) examines the different causes to which the phenomena of the barometer have been ascribed. He begins with the influence of different temperatures. It appears, he says, by observation, that a variation of the mass of the atmosphere is not a necessary consequence of an alteration of the temperature; for the mercury is often at the same height at different seasons, and at different places in the same season; and even when the height of the mercury changes simultaneously with the temperature, the change is often directly contrary to that which the change of temperature would lead one to expect. Besides, great changes of temperature take place only in the lower atmosphere; but in the higher regions they are inconsiderable. Any increment or decrement of the mass of the lower atmosphere that can be ascribed to a change of temperature, is too small to produce any considerable alteration in the height of the barometer; for in winter the height to which any considerable variation of temperature may be supposed to extend, scarcely exceeds 5000 feet, as we learn from the testimony of aeronauts and the height of the clouds; and indeed the winds that prevail on the surface of the earth, and which are the primary agents in producing a change of temperature, seldom reach higher, and in the more northern regions not so high. This cause, the effect of which is estimated by calculation, and compared with the actual variation, though not absolutely inefficient, on the supposition that the whole mass of the superincumbent column is increased by the accession of new air in proportion to the condensation, is nevertheless inadequate to the effect produced.

Mr. Kirwan next examines the efficacy of winds in producing the variations of the barometer; and these are such as reign in the lower regions of the atmosphere. If, according to Dr. Halley's theory, the rise of the barometer above its mean altitude were owing to the accumulation of air over the place of observation, occasioned by two contrary winds blowing towards that place, we should always have a calm when the mercury stands highest; but it is notorious, that the greatest mercurial heights are accompanied by an easterly or northerly wind, as Halley himself has observed. Nor can that equality of barometrical heights, which takes place in very distant countries, where very different winds prevail, be explained by this hypothesis. This hypothesis ascribes the descent of the mercury below its mean altitude to the rarefaction of the atmosphere over the place of observation, which rarefaction is owing to its exhaustion by two contrary currents; for instance, over England, if it should blow a westerly wind on the German, and an easterly wind on the Irish sea. But Mr. Kirwan thinks, that a rarefaction in such circumstances from such a cause is impossible; for if such currents took place, the northern or southern air would flow in to maintain the equilibrium in the same proportion; or if this did not happen, and that four contrary currents took place, the higher air should descend, and cause a sensible cold, which yet is seldom observed in England, when the mercury is low; on the contrary, a warm south wind commonly prevails, to whose temperature nevertheless the rarefaction cannot be ascribed. Dr. Halley's explanation of the descent of the mercury on high winds in storms

forms appears to Mr. Kirwan to be unsatisfactory. "The region of the earth," says Halley, "wherein those winds rage, not extending round the globe, the stagnant air left behind and that on the sides cannot rush in fast enough to restore the evacuation made by so swift a current, so that the air must be attenuated where the said winds continue to blow."—"Add that the horizontal motion being so quick may take off some part of the perpendicular pressure." This last reason seemed to acquire some confirmation from an experiment made by Mr. Hawksbee; for having passed a stream of air through a box in which the lower flank of a barometer was inserted, he observed the mercury to fall while the current passed through the box; as also in another barometer which communicated with the box, over which the current of air did not flow. Allowing this, the phenomenon is not sufficiently explained; for Mr. Kirwan observes, that not only during the storm, but several hours, if not days, before it, the mercury descends considerably, as Halley himself, and all who recommend the marine barometer, attest; otherwise this instrument would be useless. Mr. Caswell observes (Phil. Trans. Abr. vol. viii. p. 458.), that two days before the great storm of January 1734-5, the mercury fell $\frac{1}{8}$ of an inch below 28 inches. But if the fall were concomitant with the storm, Dr. Halley's reasons would not prove their connection. In order to a body's moving through air with such a velocity as to leave a vacuum behind it, there is a necessity that it should move at the rate of 11 or 1200 feet per second, as appears by the observations of Mr. Bricc and many others. (See Phil. Trans. for 1766, p. 266.) The insufficiency of the second reason alleged by Dr. Halley has been clearly shewn by M. de Luc; nor is the experiment of Mr. Hawksbee conclusive, as it appears that part of the air already confined in the boxes was forced out by the blast of air; and besides, Mr. Derham observed that during the greatest vehemence of storm, the mercury rises instead of falling lower. (Phil. Trans. Abr. vol. iv. pt. 2. p. 77.) Mr. Kirwan made the same observation on the 28th of February 1785, in London.

The third hypothesis is that of those who ascribe the variations of the barometer to the presence or absence of vapours in the atmosphere; but Mr. Kirwan infers, from a view of the nature of vapours, and the change they produce in the weight and elasticity of the atmosphere, that this theory does not fully account for the phenomena. If we suppose, says he, the atmosphere perfectly dry, the barometer at 30 inches, and the thermometer at 65, and then a column of it to be saturated with moisture, its elasticity being increased $\frac{1}{7}$, which, according to his computation, would be the case, it will contain $\frac{7}{8}$ of its volume less air than before saturation, since the increase of its elasticity arises from the introduction of a new elastic fluid amounting to $\frac{1}{7}$ of its bulk; and since the weight of the whole volume was at first equal to that of 30 inches of mercury, its weight will now be lessened by $\frac{1}{7}$ of 30 inches, that is nearly 0.59 of an inch. But on the other hand, it gained $\frac{1}{7}$ of its volume of vapour, and therefore its real loss of weight will be the difference of the weight of $\frac{1}{7}$ of air, and $\frac{1}{7}$ of vapour; but the weight of air is to that of vapour as 12 to 10, therefore the gain here is 0.49 of an inch, which deducted from 0.59 the loss, leaves the loss $\frac{1}{10}$ of an inch. Accordingly, this is the variation which the barometer should undergo by the passage of a column of air from absolute dryness to complete saturation; a circumstance which never takes place, as the atmosphere is never absolutely dry; and yet previously to heavy rains, we often observe the barometer to fall $\frac{3}{10}$, $\frac{4}{10}$, or $\frac{5}{10}$ of an

inch; a fall which, from the above calculation, cannot originate from the saturation of the atmosphere with vapour. Nor is there any proportion between the ascent of mercury after heavy rains, and the weight of vapour condensed; for in such cases, the mercury frequently rises $\frac{3}{10}$ or $\frac{4}{10}$ of an inch; and yet the heaviest rain seldom produces one cubic inch of water, and the weight of a cubic inch of water is not equal to that of even one tenth of a cubic inch of mercury.

Mr. Kirwan, having examined the causes to which the variable weight of the atmosphere and height of the barometer have been usually referred, and controverted their insufficiency, proceeds to explain that which alone seems to him adequate to the effects produced. This, in his opinion, is the accumulation of air over those parts of the globe in which the mercury exceeds its mean height; that is, the height suited to its situation; and the diminution or subtraction of the natural quantity of air over those regions in which the mercury falls beneath its mean height. In order to trace the origin of this accumulation and diminution, this ingenious author considers what may be called the natural state of the atmosphere, and how that state may be disturbed. The natural state of the atmosphere is that in which the barometer on the level of the sea would stand at 30 inches in serene weather, conformably to the fifth observation above mentioned. For producing this state, the weight of the atmosphere must be every where equal at the surface of the sea; and as its weight proceeds from its density and height, in order to obtain this equality of weight, it should be lowest where its density is greatest, and highest where its density is least; and these extremes of density take place in the equatorial and polar regions. Hence it follows, that if the height of the mercury be 30 inches under the equator and under the poles, the atmosphere must be highest under the equator and lowest under the poles, with several intermediate gradations. (See *Figure of the Atmosphere*.) But though the equatorial air be less dense to a certain height than the polar, yet at certain greater heights it must be more dense; for the mercurial heights at the level of the sea being equal, the masses of the corresponding atmospheric columns must be equal. The same observation applies to the extratropical columns with respect to each other, where great differences of heat prevail. Hence it follows, that in the higher regions of the atmosphere, the denser equatorial air, not being supported by the collateral extratropical columns, gradually flows to the north and south. If the affluence of the northern and southern air to the equator by the trade winds kept pace with the effluence of the superior air, some degree of equilibrium might still be maintained. But the trade winds move only at the rate of about 8 miles an hour; whereas without the tropics, or at least beyond latitude 30°, the currents of the upper atmosphere are incomparably more rapid. The mean heat of the whole space between latitude 0° and latitude 30° being only seven degrees less than the mean heat under the equator, the difference of density is not so great as to cause any rapid colliapsion of the superior columns within that space; but from latitude 30° to latitude 60°, a much smaller space, the mean annual heat over the ocean differs from that of latitude 30° by nearly fourteen degrees; and therefore, the rapidity of the upper current towards the polar regions is much greater, and will occasion frequent interruptions, during which the weight of the air will be diminished. Hence, notwithstanding the high winds that frequently prevail between the tropics, the barometer inconsiderably and but seldom varies; whereas, without them, the variations are frequent and considerable, nearly in proportion to the distance from the equator: and thus

thus the second observation is sufficiently explained. During the summer of the northern hemisphere, when it is winter in the southern, the density of the equatorial air becomes superior to that of the southern air at a much lower height than that at which it becomes superior to the northern, which is expanded by the presence of the sun in the northern tropic: the exuberance will therefore be poured on the southern regions, and a smaller quantity will flow over the northern; consequently the variations of the barometer are smaller with us in the summer season. In winter, on the contrary, the superior current is chiefly directed to the northern hemisphere, and hence the greatest mercurial heights are found in this season: and thus the third observation is illustrated and confirmed. This accumulation takes place where the columns of the inferior air are coldest and shortest, as over that part of Asia beyond latitude 35°, and east of the Caspian sea to the Frozen ocean, and over the continent of North America; and hence the barometer usually stands higher in North America, and varies less than with us even in Hudson's bay, latitude 59°. Accumulations are also found in the southern parts of the old continent; and when the rarefaction in the northern parts of Europe is frequent and considerable, the southern air flows from these tracts to restore the equilibrium, and while this current lasts, the barometer must fall in the intermediate regions; so that the descent of the mercury is never the effect of a southerly wind, but both it and this wind are the concomitant effects of a rarefaction in the northern parts. On the other hand, the mercury generally rises under a northerly or easterly wind, because the superior atmosphere is accumulated chiefly in those parts of our hemisphere from whence these winds issue, and this accumulated air passes with them to the southern regions. In the same manner, when the mercury falls before a storm, both the storm and this fall proceed from a great rarefaction of the air in the quarter towards which the storm blows, and this rarefaction is occasioned by the diminution or destruction of the superior atmosphere. As the superior accumulation is derived to us chiefly from North America, hence it is that the variations of the barometer generally begin to the westward with us in Europe, and are thence gradually propagated eastwards. In spring the current of superior air begins to flow to the south, and in autumn to return from it; hence the equinoctial storms and frequent variations of the barometer in those seasons. The quantity of equatorial air devolved on our hemisphere in different years is variable, and so is the quantity consumed in the northern regions; and hence the mean barometrical height is different in different years. In some years, the accumulation resting on the mountainous countries of the south of Asia and Europe, and the northern part of Africa, is greater than in other years; owing perhaps to a greater or earlier fall of snow: when this is the case, the northern air is lighter, and the southern colder, than usual, and south winds principally prevail, which in the northern parts must seem to be comparatively warm; and hence, when the winter is remarkably severe in the south of Europe and Asia, it is often as remarkably mild in the northern parts, and the barometer low. Although clouds and a disposition to rain frequently follow the descent of the mercury, this descent is not the immediate consequence of either clouds or rain: on the contrary, the mercury frequently rises during rain. But the rarefaction of the atmosphere, which produces the descent of the mercury, and which arises from the removal of the superior accumulation, is favourable to the production of clouds: as a heavy atmosphere, though it supports vapours once formed, obstructs evaporation: when therefore its weight is diminished, and evaporation increased, it soon becomes saturated in the higher regions, and clouds are formed.

But rain seems to arise from a subtraction of the electrical fluid, which, when the air abounds with vapours, is easily conducted to the earth. In serene and settled weather the mercury is generally high, because the greatest disturbances of the atmosphere are connected with its rarefied state, which is commonly pretty distant when the superior accumulation is considerable.

That the variations of the mercurial heights should be greater at the level of the sea than at great elevations above that level, is very natural. For supposing the mercury at the level of the sea to stand at 30 inches, and at a certain elevation above that level at 25 inches, then if the weight of the atmosphere be diminished one hundredth part, the mercury at the level of the sea should fall one hundredth part of 30 inches = 0.3 of an inch, but that on the elevation should fall one hundredth of 25 inches, = 0.25 of an inch. But it has been observed, that the variation on high mountains is beyond all proportion smaller than on the level of the sea; and this proceeds from a property which they seem to possess of condensing and accumulating the air incumbent upon them in a greater degree than the air incumbent over plains is condensed at equal heights: and hence, when the barometer on the plains falls, and that on the mountain also, it will be found, after allowing for the difference of temperature, that the fall is proportionably greater in the inferior than in the superior barometer; and, on the contrary, if the mercury ascends in both barometers, the ascent will be proportionably greater in the superior than in the inferior. To this purpose General Roy found, on the 7th of August 1775, at 9 o'clock, the correct height of a barometer on Caernarvon quay 30.075, and on the peak of Snowdon 26.418 inches; at 12 o'clock, that on the quay fell to 30.043, and that on the peak to 26.405; the fall of the mercury on the plain was therefore $\frac{1}{10000}$ of the whole, and the fall on the mountain was only $\frac{1}{12000}$ of its original height. On the other hand, at 2 o'clock, the barometer on the quay rose to 30.045, while that on the peak rose to 26.415 inches correct height; therefore that on the quay ascended only $\frac{1}{10000}$ of the whole, and that on the peak ascended $\frac{1}{12000}$ th part of its height. Yet as the descents of the mercury beneath its most usual mean height are much more frequent and considerable than its ascents above it, the variations on mountains are upon the whole proportionably smaller than at the surface of the sea. For a more particular illustration of the theory of Mr. Kirwan, and the collateral observations which he deduces from it, we must refer to his paper, *ubi supra*. See *ATMOSPHERE*, and *AURORA borealis*. For other prognostics of the weather, besides the variations of the barometer, see *WEATHER*.

Another important purpose to which the variations of the barometer have been applied, is the "measurement of altitudes." Whilst M. Pascal and M. Perrier were prosecuting experiments for ascertaining the weight of the air by means of the barometer as early as the year 1648, they found that the mercurial heights varied according to the situations, either more elevated or more depressed, in which the barometer was placed; and hence they concluded, that this instrument might serve to determine how much one place was higher than another. M. Pascal was not unacquainted with the dilatibility of the air, and he was therefore apprized of one of the difficulties that have attended experiments of this nature. The first person who estimated the height of the atmosphere on these principles was Kepler: but having, from ill-conducted experiment, very erroneous ideas of the proportional specific gravities of mercury and air, he stated it at only two or three English miles. The Honourable Mr. Boyle, deducing from experiments the proportion of the specific gravity of mercury to that of air to be as 1 to

14000, and supposing the atmosphere to be equally dense, estimated its height to be twice as great as Kepler's measure, or at least 35000 feet. But when the elasticity of the air was found to be in an inverse ratio of the space which it occupied, or that its condensation was proportional to the weight that compressed it, and of course that its dilatations were in the inverse proportion of the compressing weights, a property first discovered by Mr. Richard Townley, and demonstrated by Mr. Boyle, the height of the atmosphere was more accurately ascertained. Mr. Boyle's experiments to this purpose were published in 1661, in his "Defensio Doctrinae de Aëris Elatere contra Linum," and exhibited the preceding year before the Royal Society. The law of the dilatation of the air was discovered also by M. Mariotte; and he published an account of his experiments for ascertaining it, in 1676, in his "Essai sur la Nature de l'Air," and "Traité des Mouvements des Eaux." This law was generally admitted by philosophers, and it was confirmed by observation in all climates and at all altitudes. To this purpose, M. Bouguer (Mem. Acad. Roy. Sc. 1753.) gives us the result of the experiments made by himself and M. de la Condamine in America; and he says that he found, without any exception, that the elasticities of the same mass of air exactly corresponded to the ratio of the densities. M. Mariotte applied this general law to the investigation of the total height of the atmosphere. With this view, he collected many observations of the barometer made at small heights; and he was the first person who suggested the use of logarithms in estimating heights by the descent of the mercury in the barometer, though this method has been generally ascribed to Dr. Halley; and Halley indeed first employed tables of logarithms in the calculation of atmospherical altitudes. See Phil. Trans. N^o 181, or Abridg. vol. ii. p. 14. Dr. Halley, assuming the specific gravity of the air to water, when the barometer stood at 30 inches, and in a mean state of heat and cold, to be as 1 to 800, and that of mercury to water as 13½ to 1, (so that the weight of mercury to air is as 10800 to 1, or a cylinder of air of 10800 inches or 900 feet is equal to an inch of mercury,) inferred from these premises, that if the air were of equal density, like water, the whole atmosphere would be no more than 5.1 miles high; and that for an ascent of every 900 feet, the barometer would sink an inch. But the expansion of the air increasing in the same proportion as the incumbent weight of the atmosphere decreases, the upper parts of the air are much more rarefied than the lower, and each space corresponding to an inch of quicksilver is gradually enlarged, and therefore the atmosphere must be extended to a much greater height. As these expansions of the air are reciprocally as the heights of the mercury, they may be represented for any given mercurial height by means of the hyperbola and its asymptotes. Thus, in *Plate XI. Pneumatics, fig. 98*, the rectangles APCE, AKGE, ALDE, &c. are always equal; and consequently the sides CB, KG, LD, &c. are reciprocally as the sides AB, AK, AL, &c. (See HYPERBOLA.) If then AB, AK, AL, &c. be supposed equal to the heights of the mercury, or the corresponding pressures of the atmosphere, the lines CB, KG, LD, &c. answering to them, will be as the expansions of the air under those pressures, or the bulks which the same quantity of air will occupy; and if these expansions be taken infinitely numerous and infinitely small, their respective sums will give the spaces of air between the several heights of the barometer: i. e. the sum of all the lines between CB and KG, or the area CBKG, will be proportional to the distance or interval intercepted between the levels of two places in the air, where the mercury would stand at the heights represented by the lines AB, AK; and, therefore, the spaces of the air answer-

ing to equal parts of mercury in the barometer are as the areas CBKG, GKLD, DLME, &c.; but these areas are proportional to the logarithms of the numbers expressing the ratios of AK to AB, of AL to AK, of AM to AL, &c. Thus, by the common table of logarithms, the height of any place in the atmosphere, having any assigned height of the mercury, may very easily be found; for the line CB in the hyperbola, the areas of which represent the tabular logarithms, being 0.0144765, we shall have the following proportion: as 0.0144765 is to the difference of the logarithms of 30 and of any lesser number, so is the space answering to an inch of mercury, if the air were equally pressed with 30 inches of mercury, and every where alike, or 900 feet, to the height of the barometer in the air, where it will stand at that lesser number of inches. By the converse of this proportion, the height of the mercury may be found corresponding to the given altitude of the place. It should be observed, that the number 0.0144765 is the mean between 0.0147232, the difference of the logarithms of 30 and 29; and 0.0142404, the difference of the logarithms of 30 and 31. The first difference represents the mean density of the air between the heights of 30 and 29 inches indicated by the barometer; and the second difference represents the mean density between 30 and 31; and the density of the air at 30 inches is the mean between these two densities. This calculation of Dr. Halley is founded on the supposition of equal and uniform gravity; but sir Isaac Newton resolved the problem more generally (*Princ. Philos. Nat. Math. l. ii. § 5.*), and extended it to the true state of the case, where gravity is as the square of the distance inversely; and he shewed, that when the distances from the earth's centre are in harmonic progression, the densities are in geometric progression. He also shews, in general, what progression of the distances, on any supposition of gravity, will produce a geometrical progression of the densities so as to obtain a series of lines which will be logarithms of the densities. See also Cotes's "Hydrostatical Lectures," and "Harmonia Mensurarum," and the article *Height of the ATMOSPHERE*, and *Atmospherical LOGARITHMIC* in this dictionary. By these rules Dr. Halley calculated the following tables:

Given Heights of the Mercury.	Altitudes.		Given Altitudes.	Heights of the Mercury.
	Miles	Feet		
Inches			Feet.	Inches
30		0	0	30.00
29		915	1000	28.91
28		1862	2000	27.86
27		2844	3000	26.85
26		3863	4000	25.87
25		4922	5000	24.93
20		10947	Miles 1	24.67
15		18715	2	20.29
10		29662	3	16.68
5		48378	4	13.72
1		91831	5	11.28
0.5		110547	10	4.24
0.25		129262	15	1.60
0.1	29 or 154000		20	0.95
0.01	41 or 216169		25	0.23
0.001	53 or 278338		30	0.08
			40	0.012

Upon these suppositions it appears, that at the height of 41 miles, the air is so rarefied as to take up 3000 times the space it occupies here; and at 53 miles high it would be expanded

expanded above 30,000 times: but it is probable, says Dr. Halley, that the utmost power of its spring cannot exert itself to so great an extension, and that no part of the atmosphere reaches above 45 miles from the surface of the earth. However, it follows from the principles above stated, that the air has a finite density at an infinite distance from the centre of the earth, or such as would be represented by an ordinate drawn through the centre. But at great distances its rarity would be so great, that its resistance would be insensible, though the retardation occasioned by it has been accumulated for ages. At the moderate distance of 500 miles, the rarity is so great that a cubic inch of common air expanded to that degree would occupy a sphere equal to the orbit of Saturn; and the whole retardation sustained by this planet, after some millions of years, would not exceed what would be occasioned by its meeting with one particle of matter weighing half a grain. Hence it may be reasonably inferred, that the visible universe is occupied by air, which, by its gravitation, will accumulate itself round every body in it, in a proportion depending on their respective quantities of matter; the larger bodies attracting more of it than the small ones, and thus forming an atmosphere about each.

Dr. Halley observes, that as the weight of the atmosphere is different at different times, its lower parts will be unequally pressed, and consequently its specific gravity will be also variable. This variation he partly ascribes to the effect of heat and cold, and also to the influence of other causes; but he was of opinion, that the condensation and rarefaction, occasioned by cold and heat, and by the various mixtures of aqueous and other vapours, compensate one another; for he says, that when the air is rarefied by heat, the vapours are most copiously raised; so that though the air, properly so called, be expanded and consequently becomes lighter, yet its interstices being crowded with vapours and other matter specifically heavier, the weight of the compound may continue much the same. He alleges an experiment of Mr. Caswell upon the summit of Snowdon hill to prove, that the first inches of mercury have their portions of air sufficiently near to what he has determined; for the height of the hill being nearly 1240 yards, Caswell found the mercury to have subsided to 25.6 inches, or $\frac{1}{4}$ inches below the mean altitude of it at the level of the sea, and by his own calculation the space answering to $\frac{1}{4}$ inches should be 1288 yards.

M. De Luc has given an historical and critical detail, in his "Recherches," vol. i. p. 159, &c. of the attempts that have been made, and of the rules that have been proposed, by Maraldi, Scheuchzer, I. Casini, D. Bernoulli, Horrebow, and Bouguer, as well as those of Pascal, Perrier, Mariotte, and Halley, for applying the motion of the mercury in the barometer to the measurement of altitudes. But the subject has been further pursued, and with a peculiar degree of accuracy, by De Luc himself, sir Geo. Shuckburgh, and Gen. Roy, as we shall shew in the sequel of this article.

From the experiments of Boyle, Mariotte, Amontons, and others, it was inferred that the elasticity of the air is very nearly proportional to its density; and this principle, denominated the "Boylean law," was assumed by almost all writers on this subject. These experiments, however, were not very nice; nor were they extended to any great degrees of compression, as the density of the air was not quadrupled in any of them. By the later and more accurate experiments of Sulzer (Mém. Berlin. vol. ix.), Fontana (Opusc. Physico-Math.), M. De Luc, sir George Shuckburgh, and Gen. Roy, it has been found that the elasticity of the air does not increase quite so fast as its density. From the Berlin experiments it appears, that the elasticity of the air of the

temperature 55°, or the compressing force, increases so much more slowly than the density, that if the compressing force be doubled, the density will exceed the double by about a tenth part, &c. The law of this variation is expressed with tolerable exactness, by supposing that if D be the density of the air, and F the force compressing it, then $D = F^{1-n}$, n being a very small fraction, nearly .0015. But new experiments are wanting to ascertain the law of this inequality with precision. Nevertheless, the general result has been, that the elasticity of rarefied air is very nearly proportional to its density; and the Boylean law may in general be assumed in cases of the greatest practical importance, or when the density does not much exceed or fall short of that of ordinary air. See *ELASTICITY of the Air*.

If we suppose the air to be of the temperature of 32° of Fahrenheit, and the mercury to stand in the barometer at 30 inches, we must allow $\frac{1}{10}$ th of an inch for its descent if it be elevated 87 feet; and, accordingly, if the air were equally dense and heavy every where, the height of the atmosphere would be $30 \times 10 \times 87$ feet, or about 5 miles. But as the air is an elastic fluid, whose density is always proportional to the compressing force, the altitude of the atmosphere will be much greater; and the method of estimating it by Dr. Halley and others, admits of a familiar illustration. Suppose then that a prismatic or cylindric column of air, reaching to the top of the atmosphere, were divided into an indefinite number of layers or strata of very small but equal thickness, and that every one of the particles of air that form these strata were of the same weight at all distances from the surface of the earth; it is plain, that the quantity of air in each stratum is as the density of the stratum, or as the compressing force, that is, the weight or quantity of matter of the superior and incumbent strata; consequently the quantity of air in each stratum is proportional to the superincumbent air; but the quantity in each stratum is the difference between the column on its bottom and on its top, and, therefore, these differences are proportional to the quantities of which they are the differences. But in a series of quantities proportional to their differences, the quantities themselves and their differences will be in continued geometrical progression: e. g. let a, b, c be three such quantities; then $b : c :: a - b : b - c$; and, by alternation, $b : a - b :: c : b - c$; and, by composition, $b : a :: c : b$, and $a : b :: b : c$. Hence it appears that the densities of the strata decrease in a geometrical progression; that is, when the elevations above the centre or surface of the earth increase, or their depths under the top of the atmosphere decrease, in an arithmetical progression, the densities decrease in a geometrical progression. This principle may be applied to the purpose of measuring atmospheric altitudes in the manner of Dr. Halley above stated, or by means of that species of logarithmic curve, called from this application and use of it the "atmospherical logarithmic." (See *Logarithmic Curve*, and *Atmospherical LOGARITHMIC*.) Let ARQ (fig. 99.) represent the section of the earth by a plane passing through its centre O , and let $m OAM$ be a vertical line, and AE , perpendicular to OA , will be an horizontal line passing through A , a point on the surface of the earth. Let AE represent the density of the air at A ; and let DH , parallel to AE , be taken in proportion to AE , as the density at D is to the density at A ; and hence it is evident, that if a logistic or logarithmic curve EHN be drawn, having AN for its axis, and passing through the points E and H , the density of the air at any other point C , in this vertical line, will be represented by CG , the ordinate to the curve in that point; because it is the property of this curve, that if portions AB, AC, AD , of its axis be taken in arithmetical

metical progression, the ordinates *AE, BF, CG, DH*, will be in geometrical progression. It is another fundamental property of this curve, that if *EK* or *HS* touch the curve in *E* or *H*, the subtangent *AK* or *DS* is a constant quantity. Moreover, the infinitely extended area *MAEN* is equal to the rectangle *KAZL* of the ordinate and subtangent; and the area *MDHN* is equal to *SD* × *DH*, or to *KA* × *DH*; and, therefore, the area lying beyond any ordinate is proportional to that ordinate. These properties are analogous to the principal circumstances in the constitution of the atmosphere, on the supposition of equal gravity. The area *MCGN* represents the whole quantity of aerial matter above *C*, for *CG* is the density at *C*, and *CD* is the thickness of the stratum between *C* and *D*, and, therefore, *CGHD* will be as the quantity of air in it, and so of all the others, and of their sums, or of the whole area *MCGN*; and as each ordinate is proportional to the area above it, so each density, and the quantity of air in each stratum, is proportional to the quantity of air above it; and as the whole area *MAEN* is equal to the rectangle *KAZL*, so the whole air of variable density above *A* might be contained in a column *KAZ*, if, instead of being compressed by its own weight, it were without weight, and compressed by an external force equal to the pressure of the air at the surface of the earth; and, in this case, its uniform density would be expressed by *AE*, the measure of the density at the surface of the earth, and it would form what may be called the homogeneous atmosphere. Hence it follows, that the height of this atmosphere is the subtangent of that curve, whose ordinates are as the densities of the air at different heights, on the supposition of equal gravity. In order to determine this subtangent, we may compare the densities of mercury and air; for a column of air of uniform density, reaching to the top of the homogeneous atmosphere, counterbalances the mercury in the barometer. From the best experiments it is inferred, that when mercury and air are of the temperature of 32° of Fahrenheit, and the barometer stands at 30 inches, the mercury is nearly 10440 times denser than air; consequently the height of the homogeneous atmosphere is 10440 × 30 inches = 313200 inches = 26100 feet = 8700 yards = 5 miles wanting 100 yards. Or we may find this height by observing the variations of the barometer at known altitudes, thus; when the mercury and air are of the above temperature, and the barometer on the sea-shore stands at 30 inches, an ascent of 883 feet will cause it to fall to 29 inches. Moreover, in all logarithmic curves having equal ordinates, the portions of the axes intercepted between the corresponding pairs of ordinates, are proportional to the subtangents; and the subtangent of the curve belonging to our common tables is 0.4342945; and the difference of the logarithms of 30 and 29, which is the part of the axis intercepted between the ordinates 30 and 29, or 0.0147233 : 0.4342945 :: 883 : 26046 feet = 8680 yards = 5 miles wanting 120 yards, differing from the former result 20 yards. This difference results from the difficulty of accurately ascertaining the respective densities of mercury and air, and also of duly estimating the elevation which causes a fall of one inch in the barometer. This investigation, however, proceeds upon the supposition of equal gravity; whereas it is well known, that the weight of a particle of air decreases as the square of its distance from the centre of the earth increases. In order, therefore, that a superior stratum may produce an equal pressure at the surface of the earth, it must be denser, because a single particle of it gravitates less; consequently, the density at equal elevations must be greater than on the supposition of equal gravity, and the law of its diminution must be different.

Make $OD : OA :: OA : Od$;
 $OC : OA :: OA : Oc$
 $OB : OA :: OA : Ob$, &c: so that
Od, Oc, Ob, OA, may be reciprocals to *OD, OC, OB, OA*;
 and through the points *A, b, c, d*, draw the perpendiculars
AE, bf, cg, db, proportional to the densities in *A, B, C, D*;
 and let *CD* be supposed exceedingly small, so that the density
 may be supposed uniform through the whole stratum.
 Then we shall have, $OD \times Od = OA^2 = OC \times Oc$; and
 $Oc : Od :: OD : OC$; and $Oc : Oc - Od :: OD : OD - OC$,
 or $Oc : cd :: OD : DC$, and $cd : CD :: Oc : OD$; or be-
 cause *OC* and *OD* are ultimately in the ratio of equality,
 we have $cd : CD :: Oc : OC :: OA^2 : OC^2$, and $cd = CD$
 $\times \frac{OA^2}{OC^2}$; and $cd \times cg = CD \times cg \times \frac{OA^2}{OC^2}$; but $CD \times$
 $cg \times \frac{OA^2}{OC^2}$ is as the pressure at *C* arising from the absolute
 weight of the stratum *CD*; for this weight is as the bulk,
 as the density, and as the gravitation of each particle joint-
 ly. But *CD* expresses the bulk, *cg* the density, and $\frac{OA^2}{OC^2}$
 the gravitation of each particle. Consequently $cd \times cg$ is
 as the pressure on *C* arising from the weight of the stratum
DC; but $cd \times cg$ is evidently the element of the curvilinear
 area *AmnE* formed by the curve *Efgbn*, and the ordinates
AE, bf, cg, ab, &c. *mn*. Therefore the sum of all the ele-
 ments such as *cdhg*, that is the area *cmng* below *cg*, will be
 as the whole pressure on *C*, arising from the gravitation of
 all the air above it; but by the nature of air, this whole
 pressure is as the density which it produces, that is, as *cg*.
 Hence it appears that the curve *Egn* is such, that the area
 lying below or beyond any ordinate *cg* is proportional to
 that ordinate; and this being the property of the logarithmic
 curve, *Egn* is a curve of this nature. Besides, this curve is
 the same with *EGN*; for let *B* continually approach to *A*,
 and ultimately coincide with it. It is evident that the ulti-
 mate ratio of *B.A* to *Ab*, and of *BF* to *bf*, is that of equal-
 ity; and if *EFK, Efk*, be drawn, they will contain equal
 angles with the ordinate *AE*, and will cut off equal subtan-
 gents *AK, Ak*. The curves *EGN, Egn*, are, therefore, the
 same in opposite positions. Moreover, if *OA, Ob, Oc, Od*,
 &c. be taken in arithmetical progression decreasing, their
 reciprocals *OA, OB, OC, OD*, &c., will be in harmonical
 progression increasing (see PROGRESSION): but, from the
 nature of the logarithmic curve, when *OA, Ob, Oc, Od*, &c.
 are in arithmetical progression, the ordinates *AE, bf, cg, dh*,
 &c. are in geometrical progression. Consequently, when
OA, OB, OC, OD, &c. are in harmonical progression, the
 densities of the air at *A, B, C, D*, &c. are in geometrical
 progression; and thus the densities of the air at all eleva-
 tions may be discovered. Thus, to find the density of the
 air at *K*, the top of the homogeneous atmosphere, make *OK*
 $: OA :: OA : OL$, and draw the ordinate *LT*; *LT* is the
 density at *K*.
 The correction for the diminished gravity of the air stated
 by professor Playfair (Edinb. Trans. vol. i. p. 118.) is a
 third proportional to the semidiameter of the earth, and
 the height as computed by the ordinary rule; and for dif-
 ferent mountains, this correction is in the duplicate ratio of
 their heights. Dr. Horsley finds (Phil. Trans. vol. lxiv.),
 that in a height of 4 English miles, the diminution of den-
 sity or volume from the accelerative force of gravity would be
 only $\frac{1}{1000}$ th part of the whole, or about 48 feet; and this af-
 fect, being in the duplicate ratio of the heights, becomes at
 one mile high only three feet. Below the surface of the
 earth, it is but half the quantity; gravity within the earth
 being simply as the distance from the centre.

As the heights of the mercury in the barometer in all accessible elevations indicate the densities of the air at these elevations, the method of taking heights by this instrument may be illustrated in the following familiar manner.

It has already been observed, that if the mercury in the barometer stand at 30 inches, and the air and mercury be of the same temperature of 32° Fahrenheit, a column of air 87 feet thick has the same weight with a column of mercury $\frac{7}{8}$ of an inch thick: and therefore if in ascending the mercury sinks to 29.9 inches, the interval of ascent is 87 feet. Suppose the mercury at a higher elevation to stand at 29.8 inches, and it be required to know the height to which the barometer has been carried. The stratum through which it has been raised, as the air is less compressed and rarer, must of course be thicker. The density of the first stratum may be called 300, estimating the density by the number of tenths of an inch of mercury which its elasticity proportional to its density enables it to support. In the same manner the density of the second stratum must be 299. But when the weights are equal, the bulks are inversely as the densities; and when the bases of the strata are equal, the bulks are as the thickneses. In order therefore to obtain the thickness of the second stratum, say 299 : 300 :: 87 : 87.29, which denotes the thickness of the second stratum; and therefore the whole interval of the elevation of the barometer has been 174.29 feet. When the barometer at a higher elevation, shews the density to be 298, say 298 : 300 :: 87 : 87.584 the thickness of the third stratum, and 261.875 will be the whole ascent. By this method may be computed the following table, in which the first column is the height of the mercury in the barometer, the second column is the thickness of the stratum, or the elevation above the preceding station, and the third column is the whole elevation above the first station.

Bar.	Strat.	Elev.
30	00.000	00.000
29.9	87.000	87.000
29.8	87.291	174.291
29.7	87.584	261.875
29.6	87.879	349.754
29.5	88.176	437.930
29.4	88.475	526.405
29.3	88.776	615.181
29.2	89.079	704.260
29.1	89.384	793.644
29	89.691	883.335

In order to measure any elevation within the limits of this table, observe the barometer at the lower and at the upper stations, and write down the corresponding elevations; subtract the one from the other, and the remainder is the height required. E. G. Suppose that at the lower station the mercurial height was 29.8, and that at the upper station it was 29.1.

29.1 - - - - 793.644
 29.8 - - - - 174.291

619.353 the elevation required.

Without the aid of the table, let m represent the medium of the mercurial heights, and d their difference in tenths of an inch; then say, as m is to 300, so is $87d$ to the height

required h ; or $h = \frac{300 \cdot 87d}{m} = \frac{26100d}{m}$. Thus in the preceding example, m is 29.45, and $d = .7$; and therefore, $h = \frac{7 \cdot 26100}{29.45} = \frac{182700}{29.45} = 620.4$, differing only one

foot from the former value. The whole error of the elevation 883 feet 4 inches, the extent of the table, estimated in either of these methods, is only $\frac{1}{25}$ of an inch. It is needless however to recur to approximations, when the scientific and more accurate method first practised by Dr. Halley is equally easy. Upon the supposition of equal gravity, as we have already shewn, the densities of the air are as the ordinates of a logarithmic curve whose axis is the line of elevations. It has been also shewn, that, in the true theory of gravity, if the distances from the centre of the earth increase in an harmonic progression, the densities will decrease in an arithmetical progression; but if the greatest elevation above the surface be but a few miles, this harmonic progression will scarcely differ from an arithmetical one. Thus if AB, AC, AD , are 1, 2, and 3 miles, the corresponding elevations AB, AC, AD , will be sensibly in arithmetical progression also; for the earth's radius AC , is nearly 4000 miles. Hence it follows that $BC - AB$ is

$$\frac{1}{4000 \times 4001} = \frac{1}{16004000} \text{ of a mile, or } \frac{1}{25} \text{ of an inch,}$$

which is a quantity altogether insignificant. We may therefore assume, that in all accessible places, the elevations increase in an arithmetical progression, while the densities decrease in a geometrical progression. Consequently the ordinates are proportional to the numbers which are taken to measure the densities, and the portions of the axis are proportional to the logarithms of these numbers. Hence it follows, that we may take such a scale for measuring the densities, that the logarithms of the numbers of this scale shall be the portions of the axis, that is, of the vertical line in feet, yards, fathoms, or any other measure; and we may, on the other hand, chuse such a scale for measuring our elevations that the logarithms of our scale of densities shall be parts of this scale of elevations; and either of these scales may be found scientifically. For it is a known property of the logarithmic curves, that when the ordinates are the same, the intercepted portions of the abscissæ are proportional to their subtangents. But the subtangent of the atmospheric logarithmic is known; it is the height of the homogeneous atmosphere in any measure we please, e. g. fathoms; and we find this height by comparing the gravities of air and mercury, when both are of some determined density. Thus in the temperature of 32° of Fahrenheit, when the barometer stands at 30 inches, it is known, as the result of many experiments, that mercury is 10423.068 times heavier than air; therefore the height of the counter-balancing column of homogeneous air will be 10423.068 times 30 inches, that is, 4342.945 English fathoms. It is also known that the subtangent of our common logarithmic tables, where 1 is the logarithm of the number 10, is 0.4342945. Consequently the number 0.4342945 is to the difference D of the logarithms of any two barometric heights as 4342.945 fathoms are to the fathoms F contained in the portion of the axis of the atmospheric logarithmic, which is intercepted between the ordinates equal to these barometrical heights; or that 0.4342945 : D :: 4342.945 : F , and 0.4342945 : 4342.945 :: D : F ; but 0.4342945 is the ten thousandth part of 4342.945, and therefore D is the ten thousandth part of F .

Thus it accidentally happens, that the logarithms of the densities,

densities, measured by the inches of mercury which their elasticity supports in the barometer, are just the ten thousandth parts of the fathoms contained in the corresponding portions of the axis of the atmospherical logarithmic. Therefore if we multiply our common logarithms by 10000, they will express the fathoms of the axis of the atmospherical logarithmic. Our logarithms contain the index or characteristic, which is an integer, and a number of decimal places. Let us then remove the integer place four figures to the right hand; thus, the logarithm of 60 is 1.7781513; multiply this by 10000, and we obtain 17781.513.

This reasoning may be easily applied to practice, thus; observe the heights of the mercury in the barometer and at the upper and lower stations in inches and decimals; take the logarithms of these, and subtract the one from the other; and the difference between them, accounting the four first decimal figures as integers in the manner now proposed, is the difference of elevation in fathoms.

E. G.

Mercurial height: at the lower station 29.8 - 1.4742163
 At the upper station 29.1 - 1.4638930

Difference of logarithms $\times 10000$ - - 00103.233
 or 103 fathoms and $\frac{233}{1000}$ of a fathom, which is 619.192 feet or 619 feet $4\frac{1}{2}$ inches, differing from the approximated value before found about $\frac{1}{2}$ an inch. We have thus availed ourselves of the familiar and very intelligible illustration of the method of measuring heights by means of the barometer proposed and reduced to practice by Dr. Halley, given by an ingenious anonymous writer in the "Encyclopædia Britannica" art. "Pneumatics." By this method it was found that when the temperature of air and mercury was 32° of Fahrenheit, the difference of the logarithms of the mercurial heights was precisely equal to the number of fathoms of elevation; and it was verified upon the whole in practice, by geometrical surveys and measurements.

The utility of it, however, was of very limited extent; and it was seldom adopted, till M. De Luc first and after him Sir George Shuckburgh and general Roy, introduced in consequence of numerous observations and well-conducted experiments such improvements and corrections as were found to be necessary for expediting the practice of it and rendering the result of it accurate.

M. De Luc's apparatus of portable barometers, and their annexed thermometers, with which he made his observations, hath been already described. In the construction of his barometers he guarded as much as possible against the imperfections and faults to which those of the common sort are subject. The error arising from the repulsion of the mercury by the glass tube he remedied by substituting a siphon barometer instead of the simple upright tube, so that the repulsion of the two legs of the siphon might counteract itself. Another error resulting from air and moisture in the barometrical tube he obviated by boiling the mercury in the tube, and by other precautions. And he also shows how to correct mistakes in the estimation of heights that are owing to variations of the density of the mercury, and also of the air, occasioned by heat and cold, by means of allowances depending on two thermometers, one attached to the frame of the barometer itself and the other exposed to the open air for shewing its degree of heat; and these thermometers are to be noted both at the top and bottom of the hill. From the use of this apparatus in a great variety of observations he deduced a rule for calculating the heights of places, which he verified by numerous experiments. Dr. Maskelyne and bishop Horsley have reduced his rule from the

French to the English measure, and adapted it to the thermometers of Fahrenheit's scale. M. De Luc (see Recherches, &c. vol. i. p. 362—364) in the winter season, heated the air of his room to as great a degree as possible, and observed the rise of the barometer occasioned by the diminution of its density or specific gravity by heat; and he also noted the height of the thermometer, both before and after the room was heated. Hence he deduced a rule that when the barometer is at 27 French inches, which was the case in this experiment, an increase of heat from freezing to that of boiling water will raise the barometer 6 lines, or $\frac{1}{3}$ th part of the whole. But when the barometer is higher than 27 inches, this variation must increase in the same proportion; or it will be always $\frac{1}{3}$ th of the height of the barometer. Consequently if the height be called B , the rise of the barometer corresponding to an increase of heat from freezing to boiling water, will be $\frac{B}{54}$; and as it will be less for a less

difference of heat, if the number of degrees marked on the thermometer between freezing and boiling water be called K , and the rise of the thermometer from any given point be called H , the corresponding rise of the barometer will be $\frac{B}{54} \times \frac{H}{K}$, by the increase of heat from the given point by the number of degrees H . With a decrease of heat, H would signify the degrees of decrease, and the barometer would sink by $\frac{B}{54} \times \frac{H}{K}$. The fixed temperature of

heat to which M. De Luc reduced his observations of the barometer is $\frac{1}{3}$ th of the interval from freezing to boiling water above the former point; and if the thermometer was higher than this degree, he subtracted $\frac{B}{54} \times \frac{H}{K}$; if it was

lower, he added this quantity to the observed height of the barometer; and he thus obtained its exact height, or such as it would have been, if the density of its quicksilver had been the same as answers to the fixed degree of temperature. He thus corrected the height of both his barometers, that at the bottom and that at the top of the hill, for the particular degree of heat, indicated by a thermometer attached to the barometer at each station. These corrected heights of the barometers were those which he used in his calculations. Then, calling these two altitudes of the barometer at the lower and at the upper stations, B and b , and using $\log. B$, and $\log. b$ for their logarithms, taken out of the common tables, and assuming the four first places of figures after the index as integers, and the three remaining figures as decimals, and putting C for the mean height of a thermometer, exposed to the air at the top and bottom of the hill, the freezing point being 0, and the point of boiling water at 80, he found by his experiments that the height of the hill would be given in French toises, when C was 16 $\frac{1}{2}$, by merely taking the difference of the logarithms of the heights of the barometer, or $\log. B - \log. b$; and in any other degree of heat, would be greater or less in proportion as the rarity of the air was greater or less than in the fixed temperature; or greater or less, by $\frac{1}{27}$ th part of the whole, for every degree of the thermometer reckoned from the fixed temperature 16 $\frac{1}{2}$; and consequently the height of the place would be expressed generally in French toises by this formula, viz. $\log. B - 1 \text{ g. } b + \log. B - \log. b \times \frac{C - 16\frac{1}{2}}{215} = \log. B - \log. b \times 1 + \frac{C - 16\frac{1}{2}}{215}$. The re-

duction of this formula to English measure and to the scale of

of Fahrenheit's thermometer is performed by the astronomer royal (Phil. Transf. vol. lxiv. p. 162), in the following manner. The French foot is to the English foot as 1.06575 to 1 (Phil. Transf. vol. lviii. p. 326); and the Fahrenheit's point of freezing is 32, and that of boiling water 212, having an interval of 180 degrees. But M. De Luc's point of boiling water or 80 was marked when the barometer was at 27 French inches, that being its mean height at Geneva; but our English workmen mark the same point on Fahrenheit's scale, when the barometer stands at 30 inches, which is equal to 28 inches 1.8 lines French measure, or 13.8 lines higher than M. De Luc's barometer, when he adjusted the point of boiling water on his thermometer; and it is well known, that the heat of boiling water varies with the weight of the atmosphere. M. De Luc from his experiments inferred, that an increase of one line in the height of the barometer raises the mercury of the thermometer, placed in boiling water, $\frac{1}{113.4}$ th part of the interval between the freezing point and that of boiling water, though the rule will not apply to large variations of the barometer occasioned by very great heights above the earth's surface. The change of the boiling point in Fahrenheit's scale corresponding to a change of one line in the barometer, will be $\frac{180}{113.4} = 0.16$; and therefore 13.8 lines will produce $0.16 \times 13.8 = 2.2$ degrees of Fahrenheit's scale; and a thermometer, whose point of boiling water was marked 212, when the barometer stood at 30 English inches = 28 inches 1.8 lines French measure, will, when the barometer descends to 27 French inches, sink 2.2 degrees in boiling water, or to 209.8 or in round numbers to 210 degrees, which is distant only 178 from 32 the point of freezing. Hence it appears that an extent of 80° of M. De Luc's thermometer corresponds to an extent of 178 of our Fahrenheit's thermometer; and putting F for the degrees of this thermometer, corresponding to C of M. De Luc's, we shall have $C : F - 32 :: 80 : 178$, and $C = F - 32 \times \frac{80}{178}$, which, substituted in M. De Luc's

formula, gives $\log. B - \log. b \times 1 + \frac{C - 164}{215} = \log. B$

$$- \log. b \times 1 + \frac{F - 32 \times \frac{80}{178} - 164}{215} = \log. B - \log. b$$

$$\times 1 + \frac{80}{178} \frac{F - 32 - 167.5}{215} = \log. B - \log. b$$

$$\times 1 + \frac{F - 32 - 37.27}{478.38} = \log. B - \log. b \times 1 +$$

$$\frac{F - 69.27}{478.38} \text{ in French toises. To reduce these to our English fathoms of 6 feet each, multiply the above expression by } 1.06575, \text{ and we shall have}$$

$$\log. B - \log. b \times 1 + \frac{F - 69.27}{478.38} \times 1.06575 =$$

$$\log. B - \log. b \times 409.11 + F \times \frac{1.06575}{478.38} =$$

$$\log. B - \log. b \times \frac{409.11 + F}{448.87} \text{ or, in round numbers,}$$

$$= \log. B - \log. b \times \frac{409 + F}{449} = \log. B - \log. b \times 1 +$$

$$\frac{F - 40}{449}, \text{ which expresses the height between the two stations}$$

In these expressions B and b denote heights of the barometer, at the lower and higher stations, corrected for the

difference of heat between a fixed temperature, viz. $\frac{1}{11}$ th of the interval between freezing and boiling water, and the present heat, indicated by the thermometer attached to the barometer at each station: but it will be sufficient, and more convenient, to correct one barometer for the difference of the heat of the two. Suppose then the upper barometer is to be corrected, to reduce it to the temperature of the lower one, and that b signifies the height of this barometer, as observed and not corrected; the correction, from what has been already said, if we call D the difference of height of the thermometer attached to the barometer at the two stations, e. g. at the top and bottom of the hill, will

$$\text{be } \pm \frac{D b}{54K}, \text{ as the thermometer stands highest at the lower or upper station; and the upper barometer corrected, instead of } b, \text{ will be } b \pm \frac{D b}{54K}, \text{ which substituted in the formula, gives } \log. B - \log. (b \pm \frac{D b}{54K}) \times 1 + \frac{F - 40}{449}.$$

But the correction, on account of the difference of heat of the barometer at the two stations, may be reduced to a more easy expression, in which the variable quantity b , the height of the upper barometer, shall not appear. The fluxion of a logarithm is to the fluxion of its natural number as the modulus of the system to the natural number; and 4343 is the modulus of the common logarithms, when the four places, next the index or characteristic, are taken as whole numbers, instead of decimals, which is meant to be done in the use of the preceding formula.

Consequently $\frac{D b}{54K}$ being very small with respect to b , we shall have variation of $\log. b$: variation of $b = (\frac{D b}{54K}) :: 4343 : b$ very nearly, and hence variation of $\log. b = \pm \frac{D b}{54K} \times \frac{4343}{b} = \pm \frac{4343 D}{54K} = (\text{putting } K = 178)$

$$\pm 0.452 D. \text{ Hence } \log. (b \pm \frac{D b}{54K}) = \log. b \pm 0.452 D;$$

which, being substituted in the above formula, will give the difference of height of the two stations, in English fathoms, in a more convenient expression, viz. $\log. B - \log. b \mp 0.452$

$$D \times 1 + \frac{F - 40}{449}; \text{ where the upper sign, } -, \text{ is to be used, when the thermometer of the barometer is highest at the lower station, and the lower sign, } +, \text{ is to be used, when the said thermometer is lowest at the lower station. When } F, \text{ the height of Fahrenheit's thermometer, is less than } 40^\circ, + \frac{F - 40}{449}, \text{ becoming negative or subtractive, must be accordingly applied in the calculation. In the foregoing formula, } B \text{ denotes the observed altitude of the barometer at the lower station, and } b \text{ that at the upper station; } \log. B \text{ and } \log. b \text{ denote their logarithms taken out of the common tables, by assuming the four first figures, next following the index, as whole numbers, and considering the three remaining figures to the right hand, as decimals; } D \text{ signifies the difference of height of Fahrenheit's thermometer, attached to the barometer at the top and bottom of the hill; and } F \text{ signifies the mean of the two heights of Fahrenheit's thermometer, exposed freely for a few minutes to the open air in the shade, at the top and bottom of the hill.}$$

The formula, for the measure of heights, may be adapted to

to thermometers of particular scales, for the convenience of calculation; but the scales will be different from those of M. De Luc. The thermometer, attached to the barometer, will be divided with the interval between freezing and boiling water, consisting of 81.4 degrees (=180 × .452); the freezing point may be marked 0, and the point of boiling water will be 81.4; for then, if the difference of height of this thermometer, at the two stations, be called *d*, we shall have $d = 0.452 \times D$, for $d : D :: 81.4 : 180 :: 0.452 : 1$, and the number of degrees expressed by *d* will shew immediately the correction for the difference of heat of the two barometers. If the thermometer, designed to shew the temperature of the air, be divided with the interval between freezing and boiling water = 200, and the freezing point be marked -9, and the boiling point +191, and the heights of this thermometer, at the two stations,

be called G and I, we shall have $\frac{F-40}{449} = \frac{G+I}{2 \times 500} = \frac{G+I}{1000}$. For $F-40 = F-32-8$ is the height of Fahrenheit's thermometer, reckoned from 8 degrees above freezing, and $449 : 500 :: 180 : 200 :: 8 : 9$, and the fraction $\frac{F-32-8}{449}$ increasing both the numerator and denominator in the ratio of 449 to 500, will become $= \frac{F-32-8 \times \frac{500}{449}}{500}$

$\frac{F-32 \times \frac{500}{449} - 9}{500} = \frac{G+I}{2 \times 500} = \frac{G+I}{1000}$, because $\frac{G+I}{2} + 9 = F-32 \times \frac{500}{449}$. Hence, if the thermometer of the barometer has the freezing point marked 0, and the point of boiling water 81.4, and the difference of its height, at the two stations, be called *d*; and the thermometer for measuring the temperature of the air be divided with the interval of 200 between the freezing point and that of boiling water, and the first be marked -9, and the latter +191, and the degrees, shewn by this, at the two stations, be called G and I; the formula, that will give the height of the upper station above the lower one, in English fathoms,

will be $\log. B - \log. b \mp d \times 1 + \frac{G+I}{1000}$, which multiplied by 6, will give the height in English feet. It is to be observed, that + *d*, or - *d*, is to be used, as the thermometer, attached to the barometer, is highest at the lower or upper station; and if G and I should happen to fall below 0 of the scale, or to be subtractive, they must be applied accordingly in the calculation.

The rules, expressed in the above formula, will be in common language as follow:

I. The rule adapted to Fahrenheit's thermometer is this. Take the difference of the tabular logarithms of the observed heights of the barometer at the two stations, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals, and subtract or add $\frac{449}{1000}$ th part of the difference of the altitude of the Fahrenheit's thermometer, attached to the barometer at the two stations, according as it was highest at the lower or upper station: thus you will have the height of the upper station above the lower in English fathoms nearly. This is to be corrected in the following manner: say, as 449 is to the difference of the mean altitude of Fahrenheit's thermometer, exposed to the air at the two stations, from 40°, so is the height of the upper station found nearly to the correction of the same: which, added

or subtracted, according as the mean altitude of Fahrenheit's thermometer was higher or lower than 40°, will give the true height of the upper station above the lower, in English fathoms, and multiplied by 6 in English feet.

II. The rule adapted to two thermometers of particular scales is as follows. Take the difference of the tabular logarithms of the observed heights of the barometer, at the two stations, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals; and subtract or add the difference of the thermometer, of a particular scale, attached to the barometer, at the two stations, according as it was highest at the lower or upper station, and you will have the height of the upper station above the lower one, in English fathoms nearly; subject to the following correction: say, as 1000 is to the sum of the altitudes of the thermometer of a particular scale, exposed to the air at both stations, so is the height of the upper station above the lower, found nearly, to the correction of the same; which, added or subtracted, according as the sum of the altitudes of the thermometers, exposed to the air, is positive or negative, will give the true height of the upper station above the lower in English fathoms, and multiplied by 6, in English feet. Dr. Horsley, the present bishop of St. Asaph, has given a comparison of M. De Luc's rules with theory, reduced them to English measures of length, and adapted them to Fahrenheit's scale of the thermometer, and added tables and precepts for expediting the practical application of them in the Phil. Trans. vol. lxxiv. p. 214. See *Atmospherical LOGARITHMIC, and Fixed Points of THERMOMETERS.*

The scene of M. De Luc's first observations was mount Saleve, near Geneva. Here he selected 15 stations at different elevations; and the following table abstracted and abridged from his minute details (*Recherches, &c.* vol. ii. p. 213, &c.) shews the result of his operations:

Stations.	Heights by Leveling.	Number of Observations.	Mean heights by the barometer.	
	feet.	inches.	feet.	
1 -	216	2 -	12 -	230 $\frac{1}{2}$
2 -	428	10 -	13 -	435 $\frac{1}{3}$
3 -	586	-	13 -	591 $\frac{1}{3}$
4 -	728	8 -	21 -	732 $\frac{1}{2}$
5 -	917	-	24 -	919 $\frac{1}{2}$
6 -	1218	8 -	27 -	1221 $\frac{1}{2}$
7 -	1420	-	23 -	1418 $\frac{1}{2}$
8 -	1800	6 -	17 -	1798 $\frac{1}{2}$
9 -	1965	3 -	17 -	1962 $\frac{1}{2}$
10 -	2211	-	17 -	2210 $\frac{1}{2}$
11 -	2333	-	17 -	2331 $\frac{1}{2}$
12 -	2582	4 -	16 -	2583 $\frac{1}{2}$

The latest and most accurate experiments and observations relating to this subject, are those of sir George Shuckburgh, and general Roy. In order to render the method of measuring altitudes by the barometer more perfect, it is necessary to ascertain by appropriate experiments the expansion of mercury by any increase of temperature, and also the expansion of air by the same, or by any change of temperature; and also the variations to which its elasticity is subject.

It has been already stated, that M. De Luc estimates the expansion of quicksilver, between the temperatures of melting ice and boiling water, to be exactly 6 French lines, or .532875 decimal parts of an English inch. But he supposed the barometer to stand at 27 Fr. inches, or 28.77525 English inches; whereas, if it had stood at 30 inches, it would have

been

been .555556, because the expansion is proportional to the length of the column. It has also been shewn, that M. De Luc's boiling point is 2.2° lower than that of English thermometers, reducing it to 209.8 of Fahrenheit and making the interval between freezing and boiling only 177.8 degrees. Hence the expansion .555556 must be augmented in the proportion of 177.3 to 180, which gives for the total .5624297 or .56243, on a difference of temperature of 180°. Thus the expansion for each degree, supposing it to be arithmetical, or uniformly the same in all parts of the scale, will be .00312461. But from information communicated by M. De Luc to general Roy, it appears that the difference of temperature in his experiments amounted to about 31° of Reaumur, or 72° of Fahrenheit, above freezing; and therefore, .00312461 × 72 = .225 nearly will denote the rate of expansion, from which he deduced that for 180°.

The experiments of general Roy for ascertaining the expansion of mercury are minutely detailed in the Phil. Trans. vol. lxvii. p. 659—682. He exposed 30 inches of mercury, sustained in a barometer by the atmosphere, in a nice apparatus, by which it could be made of one uniform temperature, through its whole length; and he noted the expansions of it in decimals of an inch. The result appears in the following table; of which the first column expresses the temperature by Fahrenheit's thermometer, the second column expresses the bulk of the mercury in consequence of its expansion, and the third column shews the expansion of one inch of mercury for an increase of one degree in the adjoining temperatures.

TABLE I.

Temp.	Bulk of 30	Expan. for 1°
212°	30.5117	0.0000763
202	30.4888	0.0000787
192	30.4652	0.0000810
182	30.4409	0.0000833
172	30.4159	0.0000857
162	30.3902	0.0000880
152	30.3638	0.0000903
142	30.3367	0.0000923
132	30.3090	0.0000943
122	30.2807	0.0000963
112	30.2518	0.0000983
102	30.2223	0.0001003
92	30.1922	0.0001023
82	30.1615	0.0001043
72	30.1302	0.0001063
62	30.0984	0.0001077
52	30.0661	0.0001093
42	30.0333	0.0001110
32	30.0000	0.0001127
22	29.9662	0.0001143
12	29.9319	0.0001160
2	29.8971	0.0000177
0	29.8601	

be the true measure of the density of the air of the standard temperature. In order to obtain the exact temperature of the mercury, the observation should be made by a thermometer attached to the frame of the barometer, that it may warm and cool along with it. This, however, may be done, with sufficient accuracy, without a table; as the expansion of an inch of mercury for one degree decreases very nearly $\frac{1}{72}$ th part in each succeeding degree. If therefore we take from the expansion at 32° its thousandth part for each degree of any range above it, we obtain a mean rate of expansion for that range. When the observed temperature of the mercury is below 32°, this correction must be added, in order to obtain the mean expansion. This rule will be more exact if we suppose the expansion at 32° to be 0.0001127, as in the table. Then, by multiplying the mercurial height by this expansion, we obtain the correction to be subtracted or added as the temperature of the mercury was above or below 32°. Thus, in the former example of 72°, take 40, the excess of 72° above 32°, from 0.0001127, and we have 0.0001087. Multiply this by 40, and we have the whole expansion of one inch of mercury = 0.004348. Multiply the inches of mercurial height, viz. 29.2 by this expansion, and we have for the correction 0.12695; which, subtracted from the observed height, leaves 29.07304, differing from the exact quantity less than the thousandth part of an inch. This correction may be made by another process, still more simple; or by multiplying the observed height of the mercury by the difference of its temperature from 32°, and cutting off four cyphers before the decimals of the mercurial height: and this method will seldom err one hundredth of an inch. Having thus corrected the observed mercurial heights by reducing them to what they would have been if the mercury had been of the standard temperature, the logarithms of the corrected heights are taken; and their difference, multiplied by 10000, will give the difference of elevations, in English fathoms. Another method of applying this correction, more expeditious and not less accurate, is as follows. As the difference of the logarithms of the mercurial heights is the measure of the ratio of those heights, so likewise the difference of the logarithms of the observed and corrected heights at any station is the measure of the ratio of those heights; and, therefore, this last difference of the logarithms is the measure of the correction of this ratio. But the observed height is to the corrected height as 1 to 1.000102; and the logarithm of this ratio, or the difference of the logarithms of 1 and 1.000102, is 0.0000444. This is the correction for each degree by which the temperature of the mercury differs from 32. Therefore multiply 0.0000444 by the difference of the mercurial temperatures from 32, and the products will be the corrections of the respective logarithms. The following method of applying the logarithmic correction is more easy than the former. The correction will only be necessary, when the temperatures at the two stations are different, and it will be proportional to this difference. Therefore, if the difference of the mercurial temperatures be multiplied by 0.0000444, the product will be the correction required on the difference of the logarithms of the mercurial heights. Moreover, since the differences of the logarithms of the mercurial heights are also the differences of elevation in English fathoms, it follows, that the correction is also a difference of elevation in English fathoms; or that the correction for one degree of difference of mercurial temperature is $\frac{1}{225}$ of a fathom = 32 inches = 2 feet 8 inches. This correction of 2.8 for every degree of difference of temperature must be sub-

By this table the observed height of the mercury may be reduced to what it would have been if it were of the temperature 32. Suppose that the mercurial height is observed to be 29.2, and that the temperature of the mercury is 72°: say 30.1302 : 30 :: 29.2 : 29.0738, which would

tracted from the elevation found by the general rule, when the mercury at the upper station is colder than that at the lower. For in this case the mercurial column at the upper station will appear too short, and the pressure of the atmosphere too small; so that the elevation in the atmosphere will appear greater than it really is. Consequently the rule for this correction will be to multiply 0.0000444 by the degrees of difference between the mercurial temperatures at the two stations, and to add or subtract the product from the elevation found by the general rule, according as the mercury at the upper station is hotter or colder than that at the lower. If the expansion be considered as variable, the logarithmic difference corresponding to this expansion for the mean temperature of the two barometers may be taken. These logarithmic differences are contained in the following table, carried as far as 112, beyond which it is not probable that any observations will be made. The number for each temperature is the difference between the logarithms of 30 inches, of the temperature 32, and of 30 inches expanded by that temperature.

TABLE II.

Temp.	Log. diff.	Dec. of Fath.	Ft. In.
112°	0.0000427	.427	2.7
102	0.0000336	.436	2.7

Sir George Shuckburgh, in his barometrical observations, reckoned the equation for the expansion of mercury = .00323 of an inch for every degree of Fahrenheit's thermometer in a column of 30 inches, instead of .00312 used by M. De Luc: but this difference, he says, will not occasion an alteration in the result of any one of his observations of more than 5 inches; and he considers it as of no account. In another part of the same paper (Phil. Trans. vol. lxxii. p. 567.), he estimates this equation, allowing .00042 for the effect of the expansion of glass for 1° upon a column of 30 inches, at .00304 of an inch for each degree, when the barometer stands at 30 inches. He adds, that there is ground for the suspicion, that the expansion of mercury is not directly as the heat shewn by the barometer, but in a ratio somewhat different; owing, as he conceives, to some of the mercury being converted into an elastic vapour in the vacuum that takes place at the top of the Torricellian tube, which presses upon the column of mercury and thus counteracts in a small degree the expansion from heat. It does not, however, appear to be a considerable quantity, not amounting to above $\frac{1}{6}$ th of the whole expansion in a range of 40° of temperature. General Roy was incommoded in his experiments by the alternate expansion and condensation of the elastic vapour contained in the upper part of his tube. Lord Charles Cavendish found the difference between the expansion of mercury and glass, from 180° of heat, to be .469. And taking into the account Mr. Smeaton's dilatation of glass, the total expansion of 30 inches of mercury, says general Roy, will be .544, which gives a rate of expansion of only .003022 for each degree. Phil. Trans. vol. lxxii. p. 671. 673. 678.

After all, there will be a difference in the specific gravity of the mercury that is used, which will occasion irregularities that are not easily obviated. Mercury has been thought sufficiently pure for a barometer, when it is so far cleared of all calcinable matter as not to drag or felly the tube. Nevertheless in this state it may contain a considerable portion of other metals, particularly of silver, bismuth, and tin, which will diminish its specific gravity. It has been obtained by revivification from emmabar of the specific gravity of 14.259, and it is thought very fine if it be 13.65. The specific gravity of the mercury in the barometers used by Sir George Shuckburgh was 13.61 with 68° of heat; but it is seldom found so heavy. These variations must affect the ultimate results; and in order to obtain precision, it is absolutely necessary to know the density of the mercury that is employed. The subtangent of the atmospherical logarithmic, or the height of the homogeneous atmosphere, will increase in the same proportion with the density of the mercury; and the elevation corresponding to $\frac{1}{4}$ th of an inch of barometric height will vary in the same proportion.

Another circumstance which demands attention in this business is the temperature of the air; as the change that is produced by heat in its density is of much greater moment than that of the mercury. The relative gravity of the two, on which the subtangent of the logarithmic curve depends, and consequently the unit of our scale of elevation, is much more affected by the heat of the air than by the heat of the mercury. M. De Luc was led from his observations to conclude, that at a certain temperature, marked +16 $\frac{1}{2}$ in his scale, and nearly 69 $\frac{1}{4}$ of Fahrenheit's, the difference of the logarithms of the heights of the mercury in the barometer, at the upper and the lower stations, gave the height of the former of those stations above the latter in 1000ths of a French toise; but that at every other temperature above or below 69 $\frac{1}{4}$, a correction of .00223 of the whole

was to be added or subtracted for every degree of the thermometer. By observations still more accurate, it has been found, that the temperature at which the difference of the logarithms gives the height in English fathoms is 32°, and that the correction at other temperatures is .00243 of that difference for every degree of the thermometer. The manner of estimating the temperature of the air, adopted in all these observations, was the same; an arithmetical mean was taken between the heights of the thermometer, at the upper and lower stations, and was supposed to be uniformly diffused through the column of air intercepted between them. M. De Luc, however, was apprized of the inaccuracy of this supposition; and general Roy, too, has observed, that one of the chief causes of error in barometrical computation proceeds from the mode of estimating the temperature of the column of air from that of its extremities, which must be faulty in proportion as the height and difference of temperature are great. Indeed it seldom or never happens, that any particular stratum of air is uniformly of the same temperature. It is commonly much colder above; and it is also of different constitutions. Below it is warm, loaded with vapour, and very expandible; above it is cold, much drier, and less expandible both by its dryness and its rarity. Currents of wind, also, are often disposed in strata, which retain their places for a considerable time; and as they come from different regions, are of different temperatures and constitutions. It is neither certain that the whole intermediate stratum expands alike, nor that the expansion is equal in the different intermediate temperatures. Rare air expands less than that which is denser; and there is a particular elevation at which the general expansion, instead of diminishing the density of the air, increases it by the superior expansion of that which is below. But no general rule has been established by which we can obtain a more accurate correction than by taking the expansion for the mean temperature.

Sir George Shuckburgh has exhibited the result of several experiments on the expansion of air by a change of temperature in the following table; where is seen the increase in bulk of 1000 parts of air of the temperature of freezing and pressure of 30 $\frac{1}{4}$ inches, by an addition of 1 degree of heat in Fahrenheit's thermometer.

TABLE IV.

Observations.	Number of degrees the air was heated.	Expansion for 1° in 1000ths of the whole.	
With the first manometer,	1	14.6	2.30
	2	32.2	2.43
	3	40.3	2.48
	4	46.6	2.45
	5	49.7	2.48
	6	51.1	2.51
	7	23.7	2.36
	8	13.1	2.24
With another manometer,	9	22.0	2.38
	10	28.0	2.50
	11	21.5	2.34
	12	30.1	2.44
	13	22.6	2.44

The mean of these two sorts of observations, made with different instruments, is 2.43, viz. 1000 parts of the air at freezing become by expansion from 1° of heat equal 1002.43 parts or 1002.385 parts with the standard temperature 39° 7. Whereas

B A R

Whereas M. De Luc's experiments reduced, give this quantity equal 1002.23 parts. General Roy compared a mercurial and an air thermometer, each of which was graduated arithmetically; that is, the units of the scales were equal bulks of mercury, and equal bulks of air. Their progress is exhibited in the following table.

TABLE V.

Merc.	Diff.	Air.	Diff.
212		212 0	
192	20	194.4	17.6
172	20	176.2	18.2
152	20	157.4	18.8
132	20	138.0	19.4
112	20	118.0	20.0
92	20	97.2	20.8
72	20	75.6	21.6
52	20	53.0	22.6
32	20	31.4	21.6
12	20	11.4	20.0

As equal increments of heat produce equal increments in the bulk of mercury, the differences of temperature are expressed by the second column, and may be considered as equal; and the numbers of the third column express the same temperatures with those of the first. They directly express the bulks of the air, and the numbers of the fourth column express the differences of these bulks. These are evidently unequal, and they shew that common air expands most of all when the temperature is 62 nearly. In order to determine what was the actual increase of bulk by some known increase of heat, general Roy took a tube of a narrow bore, with a ball at one end. He measured the capacity of both the ball and the tube, and divided the tube into equal spaces, bearing a determined proportion to the capacity of the ball. This apparatus was placed in a long cylinder filled with frigorific mixtures or with water, which might be uniformly heated to the boiling temperature, and it was accompanied by a nice thermometer. The expansion of the air was measured by means of a column of mercury, which rose or sunk in the tube. The tube being of a small bore, the mercury did not drop out of it; and the bore being chosen as equal as possible, this column remained of an uniform length, whatever part of the tube it chanced to occupy. By this contrivance he was able to examine the expansibility of air of various densities. When the column of mercury contained only a single drop or two, the air was nearly of the density of the external air. If he wished to examine the expansion of air twice or thrice as dense, he used a column of 30 or 60 inches in length; and to examine the expansion of air that is rarer than the external air, he placed the tube with the ball uppermost; the open end passing through a hole in the bottom of the vessel containing the mixtures or water. By this position the column of mercury was hanging in the tube, supported by the pressure of the atmosphere; and the elasticity of the included air was measured by the difference between the suspended column and the common barometer.

The following table shews the expansion of 1000 parts of air, nearly of the common density, by heating it from 0 to 212. The first column shews the height of the barometer; the second shews this height augmented by a small column of mercury in the tube of the manometer, and therefore expresses the density of the air examined in inches; the third contains the total expansion of 1000 equal parts of air by

B A R

212°; and the fourth shews the mean expansion for each degree.

TABLE VI.

Barom.	Density of Air examined.	Expansion of 1000 p ^t by 212°.	Expansion by 1°.
29.95	31.52	483.89	2.2825
30.07	30.77	482.10	2.2741
29.48	29.90	480.74	2.2676
29.90	30.73	485.86	2.2918
29.96	30.92	480.45	2.3087
29.90	30.55	476.04	2.2455
29.95	30.60	487.55	2.2993
30.07	30.60	482.80	2.2774
29.48	30.00	489.47	2.3017
Mean	30.62	484.21	2.2840

If this expansion be supposed to follow the same rate that was observed in the comparison of the mercurial and air thermometer, we shall find that the expansion of a thousand parts of air for one degree of heat at the different intermediate temperatures will be as in the following table.

TABLE VII.

Temp.	Total Expansion.	Expansion for 1°.
212	484.210	2.0099
192	444.011	2.0080
172	402.452	2.1475
152	359.503	2.2155
132	315.193	2.2840
112	269.513	2.3754
92	222.006	2.4211
82	197.795	2.5124
72	172.671	2.5581
62	147.090	2.6037
52	121.053	2.5124
42	95.929	2.4211
32	71.718	2.3297
22	48.421	2.2383
12	26.038	2.1698
0		

In order to have a mean expansion for any particular range, as between 12° and 92°, which is the most likely to comprehend all the geodetical observations, we need only take the difference of the bulks 26.038 and 222.006 = 195.968, and divide this by the interval of temperature, 80°, and we obtain 2.4496, or 2.45, for the mean expansion for 1°.

This table, which in its present form shews the expansibility of air originally of the temperature 0, may be easily adapted to a mass of 1000 parts of air of the standard temperature 32°, by saying (for 212°), 1071.718 : 1484.210 :: 1000 : 13489; and so of the rest. Thus the following table is constructed.

TABLE VIII.

Temp.	Bulk.	Dilr.	Expn. for 1°.
212	13849	375	18.7
192	13474	387	19.3
172	13087	402	19.6
152	12685	413	20.6
132	12272	426	21.3
112	11846	443	22.1
92	11403	226	22.6
82	11177	235	23.5
72	10942	238	23.8
62	10704	243	24.3
52	10461	235	23.5
42	10226	226	22.6
32	10000	217	21.7
22	9783	209	20.9
12	9574	243	20.2
0	9331		

Hence we have the mean expansion of 1000 parts of air between 12° and 92° = 2.29.

The following table shews the result of general Roy's experiments on airs much exceeding the common density. The first column contains the densities measured by the inches of mercury which they will support when they are of the temperature 32°; the second column shews the expansion of 1000 parts of such air by being heated from 0 to 212°; and the third column is the mean expansion of 1°.

TABLE IX.

Density.	Expansion for 212.	Expansion for 1°.	
101.7	451.54	2.120	
92.3	423.23	1.996	
80.5	412.09	1.944	
54.5	439.87	2.075	
49.7	443.24	2.091	
Mean	75.7	434	2.047

General Roy made many experiments on air much below the common density, and he found, in general, that their expansibility by heat was analogous to that of air of ordinary density, being greatest about the temperature of 60°. He also found, that its expansibility with heat decreased with its density; but he was not able to ascertain the law of gradation. When reduced to about 1/4th of the density of common air, its expansion was as follows.

TABLE X.

Temp	Bulk.	Difference.	Expansion for 1°.
212	1141.504		
192	1134.429	7.075	0.354
172	1122.165	12.264	0.613
152	1108.015	14.150	0.708
132	1093.864	14.151	0.708
112	1079.636	14.228	0.711
92	1066.609	14.937	0.747
72	1042.788	20.911	1.045
52	1017.345	25.943	1.257
32	1000.000	17.845	0.892
Mean expansion			0.786

From the experiments to which we have above referred it appears, that the expansibility of air is great if when the air is about its ordinary density, and that in small densities it is greatly diminished. It appears, upon the whole, that there is little difference in the actual expansion or elastic force of air, refilled with an atmosphere + or - one third part; yet, when it is rendered extremely rare, its elasticity is wonderfully diminished. It should seem, indeed, that the elastic force of common air is greater than when its density is considerably augmented or diminished by an addition to or subtraction from the weight with which it is loaded; and this observed difference contradicts the experience of Boyle, Mariette, &c. It also appears that the law of compression is altered; for in the preceding specimen of the rare air half of the whole expansion happens about the temperature of 99°, but in air of ordinary density at 105°. As this is the case, the experiments of M. Amontons, in the Memoirs of the Academy at Paris for 1702, &c. are not inconsistent with those of general Roy. Amontons found that whatever was the density of the air, at least in cases where it was much denser than common air, the change of 180° of temperature increased its elasticity in the same proportion; for he found, that the column of mercury, which it supported, when of the temperature 50, was increased 1/3 at the temperature 212; and hence he hastily inferred, that its expansibility was increased in the same proportion; but this is by no means the case, unless we are certain that in every temperature the elasticity is proportional to the density; which still remains to be decided.

From another class of experiments made by general Roy, we learn that the elastic force of moist air is greatly superior to that of dry air; and that a very uniform increasing progression is perceived to take place from the zero of Fahrenheit, as far as 152° or 172°, and even to the boiling point. From the mean result of these experiments, which are arranged in a table, it appears, that the expansion of air, however moist, having that moisture condensed or separated from it by cold, differs not sensibly from that of dry air. Thus the rate for 32° below freezing 2.22799 is nearly the same as in dry air; but as soon as the moisture begins to dissolve and mix with the air, by the addition of 20° of heat, the difference is perceptible; for instead of 2.46675, the rate for 20° above 32° in dry air, we have 2.588 for that which is moist. In the next step of 20°, the rate for dry air is 2.5809; whereas that for moist is 2.97. In this manner the progression goes on continually increasing, so as to give 7.86854 for the mean rate on each degree of the 212°, which is near 3 1/2 times the expansion of dry air. And, lastly, the rate for the 20° between 192° and 212° is twice and one-half the mean rate, and about nine times that which corresponds to the zero of the scale, but the comparison being drawn from the mean of some particular experiments, as being probably nearest the truth, the total expansion of moist will be more than four times that of dry air; and the rate for the temperature at boiling will be nearly 15 times that which corresponds to the zero of Fahrenheit. This circumstance will probably account for the deviations from the rules established for determining heights by the barometer, which take place in the province of Quito in Peru, and at Spitzbergen, within 10 degrees of the pole. In the former situation, which is at a great elevation above the level of the ocean, the heights obtained by these rules fall considerably short of the real heights; and at the latter place they considerably exceed them. Near the surface of the earth there is a greater degree of humidity and heat in the air than there is in the higher regions of the atmosphere; and the elasticity or expansion of the lowermost section of

every column of air, whether long or short, will consequently be greater than the uppermost section of it. For the heat, by dissolving the moisture, produces a vapour lighter than air, which, mixing with its particles, removes them farther from each other, increases the elasticity of the general mass, and diminishes its specific gravity comparatively more than it doth that of the section immediately above it, where there is less heat and less moisture. Hence general Roy infers, that the equation for the air, in any assigned vertical, will gradually decrease as the elevation of the place above the sea increases, and that it will vanish at the top of the atmosphere. Between the tropics there is a great degree of humidity in the air; and, on the contrary, the polar atmospheres are very dry. The heat and moisture being greatest at the equator, there the elasticity or equation will likewise be the greatest at the level of the sea; and the zero of the scale will necessarily descend to a lower point of the thermometer, than that to which it corresponds in middle latitudes. As the elasticity of the air at the level of the sea, or equal heights above it, with the same degree of heat, will always be proportionable to the quantity of moisture dissolved in it, it will therefore gradually decrease from the equator towards the poles; that is, the zero of the scale will ascend in the thermometer, coincide with the 32d degree in the middle latitudes, and in its motion upwards, will give the equation to be applied with the contrary sign, in high latitudes. At Spitzbergen, it would seem that the specific gravity of air to mercury is about 1 to 10224, and in Peru about 1 to 13100. This difference is with great probability ascribed to the greater dryness of the circumpolar air; so that the density of the air was greater than could have been inferred merely from its compression and its temperature.

From the above account of the expansion of air, it is plain that the height through which we must rise in order to produce a given fall of the mercury in the barometer, or the thickness of the stratum of air equiponderant with a tenth of an inch of mercury, must increase with the expansion of air; and hence, if .00229 be the expansion for one degree, we must multiply the excess of the temperature of the air above 32° by 0.00229, and the product by 87, in order to obtain the thickness of the stratum where the barometer stands at 30 inches; or whatever be the elevation indicated by the difference of the barometrical heights, upon the supposition that the air is of the temperature of 32°, we must multiply this by .00229 for every degree that the air is warmer or colder than 32. The product must be added to the elevation in the first case, and subtracted in the latter. Sir George Shuckburgh deduces .0024 from his experiments as the mean expansion of air in the ordinary cases: and this is probably near the truth; because general Roy's experiments were made on air which was more free from damp than the ordinary air in the fields; and it sufficiently appears from his experiments, as already stated, that a very small quantity of damp increases its expansibility by heat in a prodigious degree. We shall now refer for a more particular account of the subject of this article to the papers of the astronomer royal and of Dr. Horsley, Philos. Transf. vol. lxiv. p. 158, &c. Id. p. 214, &c. and for the papers of Sir George Shuckburgh and general Roy to the Phil. Transf. vol. lxvii. p. 513, &c. and p. 653, &c. and also to professor Playfair's paper on the causes which affect the accuracy of barometrical measurements in the Edinb. Transf. vol. i. p. 87, &c.; and subjoin in one view a summary of the most approved and easy rules for the practice of this mode of measurement illustrated by examples.

The first is M. De L'c's method, already given in another form.

1. Subtract the logarithm of the barometrical height at the upper station from the logarithm of that at the lower, and count the index and four first decimal figures of the remainder as fathoms, the rest as a decimal fraction. Call this the elevation.

2. Note the different temperatures of the mercury at the two stations, and the mean temperature. Multiply the logarithmic expansion corresponding to this mean temperature (in Table II.) by the difference of the two temperatures, and subtract the product from the elevation, if the barometer has been coldest at the upper station; otherwise, add it. Call the difference, or the sum, the *approximated elevation*.

3. Note the difference of the temperatures of the air at the two stations by a detached thermometer, and also the mean temperature and its difference from 32°. Multiply this difference by the expansion of air for the mean temperature, and multiply the approximated elevation by 1 ± this product according as the air is above or below 32°. The product is the correct elevation in fathoms and decimals.

Example.

Suppose that the mercury in the barometer at the lower station was at 29.4 inches, that its temperature was 50°, and the temperature of the air 45°; and let the height of the mercury at the upper station be 25.19 inches, its temperature 46, and the temperature of the air 39. Here we have

Merc. heights	Temp. merc.	Mean	Temp. air.	Mean
29.4	50	48	45	42
25.19	46		39	
1. Log. of 29.4	- - - - -	- - - - -	- - - - -	1.4683473
Log. of 25.19	- - - - -	- - - - -	- - - - -	1.4012282
				<hr/>
Elevation in fathoms	- - - - -	- - - - -	- - - - -	671.191

				<hr/>
Product = the correct elevation	- - - - -	- - - - -	- - - - -	685.228

II. Sir George Shuckburgh's method.

1. Reduce the barometrical heights to what they would be if they were of the temperature of 32°.

2. The difference of the logarithms of the reduced barometrical heights will give the approximate elevation.

3. Correct the approximate elevation as before.

Example, the same as before.

1. Mean expansion for 1° from Table I.	- - - - -	0.000111
18° × 0.000111 × 29.4 =	- - - - -	0.059
Subtract this from	- - - - -	29.4
		<hr/>
Reduced barometrical height	- - - - -	29.341
Expansion from Tab. I. is	- - - - -	0.000111
14° × 0.000111 × 25.19 =	- - - - -	0.039
Subtract from	- - - - -	25.190
		<hr/>
Reduced barometrical height	- - - - -	25.151
2. Log. 29.341	- - - - -	1.4674749
Log. 25.151	- - - - -	1.4005553
		<hr/>
Approximated elevation	- - - - -	669.196
3. This multiplied by 1.0238 gives	- - - - -	685.125

Sir George Shuckburgh has computed a series of tables, and given precepts for estimating the heights of mountains by means of these tables; for which we refer to his own account, ubi supra.

Obs. 1. If 0.000101 be supposed the mean expansion of mercury for 1°, the reduction of the barometric heights will be had with sufficient exactness by multiplying the observed heights of the mercury by the difference of its temperatures from 32, and cutting off four more decimal places: thus $29.4 \times \frac{1}{10000}$ gives for the reduced height 29.347, and $25.19 \times \frac{1}{10000}$ gives 25.155, and the difference of their logarithms gives 669.4 fathoms for the approximated elevation, which differs from that given above by no more than 15 inches.

Obs. 2. If 0.0024 be taken for the expansion for 1°, the correction for this expansion will be had by multiplying the approximated elevation by 12, and this product by the sum of the differences of the temperatures from 32°; counting that difference as negative when the temperature is below 32°, and cutting off four places: thus, $669.196 \times 12 \times \frac{1}{13} + 07 \times \frac{1}{10000} = 16.061$, which added to 669.196 gives 685.257, differing from the former only 9 inches.

III. Another rule may be derived from the same premises; and it will be sufficiently exact for all geometrical purposes. It requires no tables, and may be easily remembered.

1. The height through which we must rise in order to produce any fall of the mercury in the barometer, is inversely proportional to the density of the air; that is, to the height of the mercury in the barometer.

2. When the barometer stands at 30 inches, and the air and quicksilver are of the temperature 32, we must rise through 87 feet, in order to produce a depression of $\frac{1}{100}$ th of an inch.

3. But if the air be of a different temperature, the 87 feet must be increased or diminished by 0.21 of a foot for every degree of difference of the temperature from 32°.

4. Every degree of difference of the temperatures of the mercury at the two stations makes a change of 2.833 feet, or two feet ten inches in the elevation. Hence is deduced the following rule.

1. Take the difference of the barometric heights in tenths of an inch; and call it *d*.

2. Multiply the difference *a* between 32, and the mean temperature of the air by 21, and take the sum or difference of this product and 87 feet. This is the height through which we must rise to cause the barometer to fall from 30 inches to 29.9: call this height *b*. Let *m* be the mean between the two barometric heights. Then $\frac{30db}{m}$ is the

approximated elevation very nearly. Multiply the difference δ of the mercurial temperatures by 2.83 feet, and add this product to the approximated elevation, if the upper barometer has been the warmest; otherwise subtract it. The result, that is the sum or difference, will be the corrected elevation.

Example, as before.

$$\begin{aligned} d &= 294 - 251.9 = 42.1 \\ b &= 87 + 10 \times 0.21 = 89.1 \\ m &= \frac{294 + 15.19}{2} = 27.29 \end{aligned}$$

$$\text{Approximated elevation} = \frac{30 \times 42.1 \times 89.1}{27.29} = 4123.24 \text{ feet.}$$

$$\text{Correction for temp. of mercury} = 4 \times 2.83 = 11.32$$

Corrected elevation in feet - - - - 4111.92
The same in fathoms - - - - 685.32
differing from the former only 15 inches

This rule may be expressed by the following formula, which is simple and easily remembered; *a* being the difference between 32° and the mean temperature of the air, δ the difference of barometric heights in tenths of an inch, *m* the mean barometric height, δ the difference between the mercurial temperatures, and *E* the correct elevation. $E = \frac{30(87 \pm 0.21a)d}{m} \pm \delta \times 2.83$. BAROMETZ, in Botany. See POLYPODIUM.

BARON, a person who holds a barony.

Baron is a term whose origin and primary import are much contested. Some will have it originally denote a man, *varus*; some a hero, or valiant man; some a libertinus, or free-man; some a great or rich man; some a vassal or liege-man. — Menage derives it from the Latin *baro*, which we find used in the pure age of that language for *vir*, a stout or valiant man; whence, according to this author, it was that those placed next to the king in battles were called *barones*, as being the bravest men in the army; and as princes frequently rewarded the bravery and fidelity of those about them with fees, the word came to be used for any noble person who holds a fee immediately of the king. — Hildore, and after him Camden, take the word in its original sense, to signify a mercenary soldier. Messieurs of the Port Royal derive it from *baris*, weight, or authority. Cicero uses the word *baro*, for a stupid brutal man; and the old Germans make mention of *luffetting a baron*, i. e. a villain; as the Italians still use the word *barone*, to signify a beggar. — M. De Marca derives baron from the German *bar*, men or free-man; others derive it from the old Gaulish, Celtic, and Hebrew languages. But the most probable opinion is, that it comes from the Spanish *varo*, a stout, noble person; whence wives come to call their husbands, and princes their tenants, *barons*. In the Salic law, as well as the laws of the Lombards, the word *baron* signifies a man in the general, and the old glossary of Philomenes translates baron by *varus*, man.

BARON, the title of a lord or peer of parliament, being the next degree below that of a viscount. A baron hath the title of Right Honourable, and in all acts and proceedings is styled Most noble Lord. The parliamentary robe of a baron is scarlet cloth, lined with white satin, having on the right side two guards of Minerva, or ermine, which signifies his degree. The coronet of a baron is a rim of gold, having thereon six pearls: this coronet was granted them by Charles II. by patent bearing date 6th July 1661, before which they wore a crimson cap turned up with ermine, and on the top a tassel of gold, now called a baron's cap. A baron may appoint three chaplains. In ancient records, the word barons included all the nobility of England, because regularly all noblemen were barons.

The word baron of itself originally did not, more than peer, signify an immediate vassal of the king; for earls palatine had their barons, that is, their immediate tenants; and in old records, the citizens of London are styled barons, and so are the representatives of the cinque ports called to this day. Baron, therefore, at first signified only the immediate tenant of that superior whose baron he is said to be; but by length of time it became restrained to those who, properly and exactly speaking, were *barones regis* & *regni*: and even not to all of these, but to such only as had manors and courts therein; for though, by the principles of the feudal constitution, every immediate military tenant of

the crown, however small his holding, was obliged to assist the king with his advice, and entitled likewise to give or refuse his assent to any new law or subsidy, that is, to attend in parliament; this attendance was too heavy and burthenome upon such a had only one or two knight's fees, and could not be complied with without their ruin. Hence arose the omission of issuing writs to such, and which, being for their ease, they acquiesced in, attendance in parliament being considered at that time as a burthen. Thus they lost that right they were entitled to by the nature of their tenure, until the method was found out of admitting them by representation. Hence arose the distinction between tenants by barony or tenure, and tenants by knight's service in the capite of the king. The former were such military tenants of the king, as had estates so considerable as qualified them without inconvenience to attend in parliament, and who were therefore entitled to be summoned: the quantum of this estate was regularly thirteen knight's fees and one third, as that of a count or earl was twenty; that is, as a knight's fee was then reckoned at 20*l. per annum*, the baron's revenue was 400 marks, or 26*l.* 13*s.* 4*d.*

Such was the nature of all the baronies of England, for about two hundred years after the conquest: and they are called baronies by tenure, because the dignity and privileges were annexed to the lands they held; and if these were alienated with the consent of the king (for without that they could not), the barony went over to the alienee. Of these Matthew Paris tells us there were 250 in the time of Henry III.; and whilst they stood purely on this footing, it was not in the king's power to increase the number of the baronies: though of barons perhaps he might; for as William the Conqueror was obliged to gratify several of his great officers, according to the number of men they brought, with two or more baronies, whenever these fell into the hands of the crown by escheat, either for want of heirs, or by forfeiture, it was in the king's power, and it was his interest, to divide them into separate hands. The same thing likewise happened, when, by an intermarriage with an heiress, more baronies than one came into the hands of a nobleman, and escheated to the crown.

But the number of these feudal baronies could not, strictly or properly speaking, be increased by the king; for they could be created only out of lands, and there were no lands vacant to create new ones out of, for the king's demesnes were in those days unalienable. However we find, at the end of Henry the Third's reign, and even in John's, that the number of baronies were actually increased, and a distinction made between the *barones majores* and *minores*.

The *majores* were those who stood on the old footing of William, and had lands sufficient in law, namely, the number of the knight's fees requisite. The *minores* were such as held by part of a barony; and when an old barony descended to, and was divided among sisters, in which case, when the husband of the sister whom the king pleased to name was the barren of parliament, or else was newly carved out of the old baronies that had fallen in by escheat; as supposing the king had granted six knight's fees of an old barony to one to hold with all the burthens and to the service of an entire barony, and the remaining seven and one-third to another on the same terms. But the attendance of these minor barons also at length became too burthenome for their circumstances, and many of them were glad to be excused. The king took then the power of passing by such as he thought unable, by not sending them writs of summons; and John extended his prerogative even to omit summoning such of the *majores* as he imagined were inclined

to oppose him: this however at length he was obliged to give up; for in his magna charta it is said, "ad habendum commune consilium regni faciemus summoneri archiepiscopos, episcopos, abbates, comites, & majores barones regni, sigillatim per literas nostras."

The *barones majores* were there fully and plainly distinguished from the *minores*; and we apprehend it will not be doubted they were such as had the full complement of knight's fees that made up an ancient barony; and accordingly we find, in 1255, when Henry the Third had neglected summoning some of these, the others refusing to enter on any business, "quia omnes tunc temporis non fuerunt, juxta tenorem magnæ chartæ suæ, vocati; et ideo, sine paribus suis absentibus, nullum voluerunt tunc responsum dare, vel auxilium concedere, vel prestare." No king since ever omitted to summon all the greater nobility, until Charles the First was prevailed upon to forbid the sending a writ to the earl of Bristol, by Buckingham, who was afraid of being accused by that nobleman; but on the application of the house of lords, and their adjourning themselves from day to day and doing no business, the writ at last was issued.

In the reign of Henry the Third also, the king's prerogative of summoning or omitting the lesser barons was likewise ascertained by an act of parliament since lost, as we find by these words from history: "Ille enim rex (scilicet Henricus Tertius) post magnas perturbationes & enormes vexationes inter ipsum regem, Simonem de Monteforti & alios barones, motas & supitas statuit et ordinavit, quod omnes illi comites & barones regni Angliæ, quibus ipse rex dignatus est brevia dirigere, venerent ad parlamentum suum, & non alii, nisi forte dominus rex alia illa brevia illis dirigere voluisset;" and from henceforth no nobleman could sit in parliament without a writ. But there was this difference between the greater and the lesser barons, that the former had a right to their writ *ex debito justitiæ*, to the latter it was a matter of favour; but when summoned, they being really barons, had the same rights with the rest, though sitting not by any inherent title, but by virtue of the writ. The other lesser barons, who were generally omitted to be summoned, by degrees mixed with the other king's tenants *in capite*, and were thenceforth represented by the knights of the shires.

But these baronies by tenure being long since worn out among the laity, it is proper to proceed to the two ways now in being of creating peers; by writ, and by letters patent. It was lord Coke's opinion, and in this he has been followed ever since, that a writ to any man, baron or no baron, to sit in parliament, if once he hath taken his seat in pursuance thereof, gains a barony to him and the heirs of his body; and though the law, principally on the authority of that great lawyer, is now so settled, certainly it is comparatively but a novel opinion, and very ill to be supported by reason. The words of the writ are: "Rex tali salutem quia de advamento & assensu consilii nostri, pro quibusdam arduis & urgentibus negotiis statum & defensionem regni nostri Angliæ concernentibus, quoddam parlamentum nostrum apud Westmonast. tali die talis mensis proximo futuro teneri ordinavimus & ibidem vobiscum, ac cum prelatibus magnatibus & proceribus dicti regni nostri, colloquium habere & tractatum; vobis in fide & ligeantia quibus nobis tenemini firmiter injungendo mandamus, quod consideratis dictorum negotiorum arduitate & periculis imminuentibus, cessante executione quacunque, dictis die & loco personaliter interfutis nobiscum, ac cum prelatibus magnatibus & proceribus super dictis negotiis tractaturi, vestrumque consilium impensuri, & hoc sicut nos, & honorem nostrum, ac expeditionem negotiorum prædictorum diligitis, nullatenus omittatis."

That this writ must be obeyed there is no doubt, for every subject is by his allegiance obliged to assist the king with faithful counsel; but what right the party summoned acquired thereby, is the question. The words are not only personal to him, but restricted likewise to a particular place and time; and, accordingly, in ancient times we find many persons summoned to one parliament, omitted in the next, and summoned perhaps to the third. There is not a word therein that hints at giving the least right to an heir; and what reason can be assigned why a man by this writ should gain an estate of inheritance in a peerage, when in letters patent it is admitted that he gains only an estate for life, without the word *heirs*. That anciently there was no such notion appears from the summons to parliament, where frequently we find the grandfather summoned, the father passed by, and the grandson afterwards summoned; nay, in the rolls there are instances of ninety-eight persons being summoned a single time only, and neither themselves nor any of their posterity ever taken notice of afterwards. Or if we were to allow that this writ created an inheritance, what reason can be given why it should be an estate tail only, and be confined to the heirs of the body, and not, as all other new inheritances created generally, go to the collateral heirs?

But in order to discover plainly what privileges persons so called by writ had, or could obtain in those times, it will be proper to distinguish them into three kinds of persons: first then, they were either some of the *minores barones by tenure*, and these, when called, had certainly all the privileges of the greater, or else they were not barons at all, but plain knights or gentlemen; and in respect to these, it is plain they had a right to deliberate, debate, and advise; but the better opinion is, they had no right to vote, but were assistants and advisers only, as the judges are at present, for it is absurd to suppose that in those times, when the commons were low and inconsiderable, and the barons were more powerful than the crown, that the latter should suffer their resolutions to be over-ruled at the pleasure of the king, by calling in such numbers as we find he often did, which must have been the case if all he had summoned had votes. But these two kinds of persons gained by their writ or sitting in consequence of it, originally, no farther right than to be present at that time. However, by many of these persons and their heirs having been constantly summoned, especially since Henry the Seventh's reign, and the ancient practice of omitting any who had been very frequently so going into disuse, the distinction between the greater and lesser barons was forgot, and that opinion prevailed which my lord Coke had adopted, and which is now the law, that a man having once sat in parliament in pursuance of the king's writ, acquires thereby an estate tail to him and the heirs of his body.

There was yet another kind of persons, not peers, that might be summoned by writ: these were the eldest sons of peers, to whom the father's barony must descend; and in such case, if the heir was called by the name of a barony that was in his father, he was a baron to all intents and purposes. But it seems very plain that this was not a new creation of a barony, for in that case the son so called should have been the lowest peer, whereas the practice is contrary; and we find no instance of a baron's son sitting on such a summons, unless the father had another barony by which he might sit: if the father indeed had a higher title, that has been reckoned sufficient to support his seat, though his only barony was transferred to the son. This then being no new creation, but a temporary transfer only of an old peerage, it should seem that this title, when once merged in the greater

by the father's death, should go according to the old limitation; but of late we find them considered as new creations. On the death of the earl of Derby, sir Edward Stanley, his sixth cousin, succeeded, and sat in parliament as baron Strange by Henry the Seventh's creation: but an eldest son of a former earl of Derby, having been called by writ while his father was living, the duke of Athol, as his heir by the female line, sat by the same title of baron Strange of king Charles the First's creation.

The descent of these two kinds of baronies is directed by the rules of the descent of other inheritances at common law; and, consequently, females are capable of succession, but with two exceptions: first, that half-blood is no impediment, and, consequently, the half-brother excludes the sister; secondly, that the honour is not divisible; and, therefore, if there be two or more sisters heiresses, the title is in abeyance, that is, is suspended until the king makes choice of one of them and her heirs; though by constant usage the law seems to be verging fast to a constant descent to the eldest.

The third method of creating peers is by letters patent, which is the most usual, and esteemed the most advantageous way; because a peerage is thereby created, though the new nobleman has never taken his seat, which is not the case of a barony by writ. As to the manner of these creations, there has a notable difference intervened since the accession of Henry the Seventh, from what was the practice before Richard the Second. In his eleventh year began this method of creating by patent, in favour of John de Beauchamp, who, though summoned, never sat there, but was attainted by the next parliament, and afterwards executed. But the attainder out of the case, his patent in law could never have been deemed valid, because Michael de la Pole was the lord chancellor who affixed the seal to it, which had been before taken from him by act of parliament, and he declared incapable of ever having it again. This then was a single and ineffectual attempt of that weak prince to create a new peer without the assent of parliament, which was the usual way, above thirty having been made so in that very reign.

His successors were too wise to follow his example; for every barony newly created, till the union of the roses, which were about fourteen, was every one of them, as appears on the face of the patents, by authority of parliament; if we except two or three: and even these, on a close examination, will appear not to be new baronies, but regrants of old feudal baronies by tenure, which undoubtedly were all in the sole disposition of the king.

But Henry the Seventh having trodden down all opposition, was fortunate enough to carry the point Richard had vainly attempted; and acquired for his successors that prerogative which they have since enjoyed, of creating peers at pleasure. The descent of these titles created by patent is directed by the words of the creation: if heirs are not mentioned, it is only an estate for life; if to a man and heirs of his body, females are not excluded: but the general way is, to the heirs male of the body lawfully begotten of the grantee, perhaps with remainders over, and they descend as other estates entailed. The case of the duchy of Somerset was singular: Edward Seymour having three sons by two venters, was created duke of Somerset, and his heirs male of his second marriage, remainder to his heirs male by his first. This title continued near two hundred years in the younger branch, until upon its failure in Charles the sixth duke of Somerset, sir Edward Seymour, the heir by the prior marriage, succeeded by virtue of the remainder.

BARONS by *Ancient Tenure* were those who held by certain territories of the king, who still reserved the tenure in chief

to himself. We also read of *barons by temporal tenure*; who are such as hold honours, castles, manors, as heads of their barony, that is, by grand serjeanty; by which tenure they were anciently summoned to parliament. But at present a baron by tenure is no lord of parliament, till he be called thither by writ.

The barons by tenure, after the Conquest, were divided into *majores* and *minores*, and were summoned accordingly to parliament; the *majores*, or greater barons, by immediate writ from the king; the *minores*, or lesser barons, by general writ from the high sheriff, at the king's command.

The ancients distinguished the greater barons from the less, by attributing high and even sovereign jurisdiction to the former, and only inferior jurisdiction over smaller matters to the latter. By the late jurisdiction act (20 Geo. II.) the civil jurisdiction of a baron in Scotland is reduced to the power of recovering from his vassals and tenants the rents of his lands, and of condemning them in mill-services; and also of judging in causes where the debt and damages do not exceed 40s. sterling. His criminal jurisdiction is, by the same statute, limited to assaults, batteries, and other smaller offences, which may be punished by a fine not exceeding 20s. sterling, or by setting the offender in the stocks in the day time not above three hours; the fine to be levied by pointing, or by one month's imprisonment. The jurisdiction formerly competent to proprietors of mines and coal or saltworks over their workmen, is reserved; and also that which was competent to proprietors who had the right of fairs or markets, for correcting the disorders that might happen during their continuance; provided that they exercise no jurisdiction inferring the loss of life or demembrement.

Barons of the Exchequer are four judges, one of whom is called the chief baron, and the other three puisne barons, to whom the administration of justice is committed in causes between the king and his subjects touching matters belonging to the exchequer, and the king's revenue. They are called *barons*, because barons of the realm were used to be employed in that office.

The lord chief baron is created by letters patent to hold this dignity *quamdiu se bene gesserit*, wherein he hath a fixed estate; for the law intends this an estate for life. He alone without the other *barons* sits at Guildhall the afternoon in term time upon *nisi prius* in London, takes audits, accounts, recognizances, presentations of officers, and many other things of importance. In the absence of the lord chief baron, the other three barons supply his place according to their seniority.

Their office is also to look to the accounts of the king, to which end they have auditors under them; as well as to decide causes relating to the revenue, brought by any means into the exchequer: so that of late they have been constantly persons learned in the law; whereas formerly they were *majores & discretiores in regno, sive de chero essent, sive de curia*. See *COURT OF EXCHEQUER*.

Barons of the Cinque Ports, are members of the house of commons, elected by the five ports, two for each port. See *CINQUE PORTS*.

Those who have been mayors of Corfe-castle in Dorsetshire, are also denominated barons; as were formerly likewise the chief citizens of London.

Baron, in *Law*, is also used for the husband in relation to the wife; which two, in law, are called *baron* and *seignior*, and are considered as one person, so that in trials of any sort they are not allowed to be evidence for or against each other. See *HUSBAND AND WIFE*.

Baron and Fief, in *Heraldry*, are terms used to ex-

press the arms of husband and wife; as thus, he beareth *baron and fief*. The modern expression is, he beareth *impaled*.

Baron, Court. See *COURT*.

Baron, prender de. See *PRENDER*.

Baron, Robert, in *Biography*, a dramatic author, who lived during the reign of Charles I. and the protectorate of Oliver Cromwell. From Cambridge, where he received part of his education, he removed to Gray's Inn, of the honourable society of which he became a member. At the university he wrote a novel called the "Cyprian Academy," containing two dramatic pieces, intitled "Deorum Dona," a masque, and "Gripus and Hegio," a pastoral. His tragedy of "Miza," which is a more regular play, was probably written at a riper age.

Baron, Michel, a celebrated French actor, was the son of a shop-keeper of Loudun, who himself went upon the stage, and born at Paris in 1652. He first joined the company of Raftin, and afterwards that of Moliere, in which connection he was universally admired and applauded. Baron was equally successful both in tragedy and comedy; although it is said he acquired his principal reputation in the former department. Racine, on occasion of introducing his Andromache on the stage, gave instructions to the other actors with respect to the performance of their several parts; but addressing Baron who was to act Pyrrhus, he said to him, "To you, sir, I have no instructions to give; your own heart will tell you more than my lessons can inform you." Preachers are said to have attended in a grated box to study his action; "and thence (says Voltaire) went to declaim against the theatre." Such was his vanity, that in allusion to the title that was bestowed upon him of the "Roscian" of his age, he said, that "every century produced a Cæsar, but that it required 2000 years to produce a Baron." He was highly cared for by persons of distinction, although he sometimes was mortified by their reflections. At length, disgusted by this circumstance, or influenced by some other motive, he withdrew from the stage in 1691, and enjoyed a pension from the king. After an interval of 29 years he resumed his profession, and at the age of 68 was as much applauded as ever. In September 1729, his infirmities reduced him to the necessity of retiring, and he survived only two months. Baron was a writer as well as an actor, and composed several comic pieces for the theatre; which are said to be lively and amusing, and to exhibit much knowledge of the stage and of the world. He also wrote some poems. A collection of his works was printed at Paris, in two vols. 12mo. in 1736; and in three vols. in 1760. But some of the pieces contained in this collection are supposed not to be his. Voltaire's Age of Lewis XIV. Nouv. Dict. Hist.

Baron, Bonaventure, whose true name was *Fitzgerald*, was a native of Clonacill, in the county of Tipperary, in Ireland, and educated under the care of his uncle Luke Wadding, a Franciscan friar at Rome, who induced him to assume the habit of this order. He resided at Rome, where he was for a considerable time prælector of divinity in the college of St. Isidore, founded by his uncle in 1625, about 60 years, and died there, after having lost his sight, and at an advanced age, in the year 1696. He was distinguished by the purity of his Latin style, and wrote many books both in prose and verse in that language. His chief work was his "Theologia," in 6 vols. printed at Paris in 1676. Biog. Brit.

BARONET OF ENGLAND, an hereditary dignity by patent, next to that of a baron instituted by king James the First on the 22d of May 1611. The first baronet that was created was sir Nicholas Bacon of Redgrave in Suffolk, whose

whose successor is therefore styled *Primus Baronorum Angliæ*. At the first institution of this order the king engaged that the number should not exceed two hundred, and that each should pay into the exchequer as much as would pay thirty foot soldiers at eight-pence per diem to serve in the province of Ulster in Ireland; and for their distinction, as an honourable augmentation, they bear in their coat of arms either in a *canton*, or in an *escutcheon* of pretence, the arms of the ancient kings of Ulster, being *argent a hand, sinister, couped at the wrist, extended in pale gul s.* Barons and their eldest sons have this peculiar privilege, that they may be knighted if they please, upon knowledge thereof given, to the lord chamberlain of the household, or vice-chamberlain for the time being, or in their absence, to any other officer attending his majesty's person; and in all commissions, writs, and other deeds, the style of *Baronet* is to be placed at the end of their surnames, as a necessary and legal addition of dignity, as the addition of *Sir* to be placed before their Christian names, and to their wives the title of *Lady* or *Dame*. Baronets have precedency before all knights, except those of the garter, and knights bannerets. No patent for creating a baronet can now pass the great seal until the following certificate is obtained:

“To all and singular to whom these presents shall come, we, the king's heralds and pursuivants of the College of Arms, London, do hereby certify that the family, arms, and pedigree of _____ have been duly registered in this college pursuant to the tenor of his majesty's warrant under his royal signet and sign manual, bearing date the _____ day of _____ 1783, for correcting and preventing abuses in the order of baronets. In witness, &c.”

BARONETS of Ireland, an hereditary dignity instituted 30 Sept. 1619, the same as those in England, and bearing likewise the arms of Ulster as an augmentation.

BARONET of Nova Scotia. This order is also hereditary, and was instituted in Scotland by king Charles I. 28th May 1625, for advancing the plantation of Nova Scotia in America, and for settling a colony there, to which the aid of these baronets was designed. As an augmentation to their arms, they bear either in a *canton* or in an *in-escutcheon* the ensign of Nova Scotia, being *argent a cross of St. Andrew azure charged with an escutcheon of the royal arms of Scotland; supported on the dexter by the royal unicorn, and on the sinister, by a savage, or wild man, proper; and for the crest, a branch of laurel, and a thistle issuing from two hands conjoined, the one being armed and the other naked, with this motto, Munit hæc et altera vincit*; and for their greater honour and dignity they were, by royal sign manual, bearing date 17th Nov. 1629, allowed to “wear and carry about their necks in all time coming an orange-tawny silk ribbon, whereon shall hang pendant in an *escutcheon orment a fîer azure thereon an escutcheon of the arms of Scotland with an imperial crown above the escutcheon, and inscribed with this motto, Fax mentis bonæ gloria*.”

BARONLE CAPUT. See **CAPUT**.

BARONIUS, CÆSAR, in *Biography*, a learned cardinal, was born at Sora, in the kingdom of Naples, in 1538, and educated first at Veroli, and then at Naples. Having finished his studies at Rome, he entered in 1560 into the congregation of the oratory founded by St. Philip de Neri, and having received the order of priesthood, he was elected superior-general of the congregation, upon the death of its founder in 1583. Pope Clement VIII. chose him for his confessor, made him apostolical protonotary, and in 1596 raised him to the dignity of cardinal. He was afterwards

made librarian of the Vatican. On the death of Clement, he had many votes in the conclave for the pontificate; but the Spanish party prevented his election, because he had asserted in his annals, that the crown of Spain founded its title to Sicily on false evidence. His assiduous application at length so debilitated his frame, that he died in 1607 at the age of 68 years. His character was distinguished for piety and probity, and mildness of disposition, as well as for extensive erudition. His chief work was his “*Ecclesiastical Annals*,” which he began at the age of 30, and prosecuted through the greatest part of his life. Of these he lived to publish 12 vols. in folio, the first of which was printed in 1588, and the last in 1607; and he brought down the history of the church to 1198. This voluminous and elaborate work was undertaken with a view of counter-acting the influence of the protestant compilation by the centuriators of Magdeburgh, which was intended to expose the abuses and inconsistencies of the Romish church; and the author, adhering rigidly to his main object, and approving himself a bigoted partizan of the see of Rome, has on many occasions sacrificed truth to the prejudices and interests of a party. He has been charged even with intentional misrepresentations; and he has been betrayed by his imperfect acquaintance with the Greek language into many errors, and by his credulity into the recital of many fables, which have been rejected by many judicious writers of his own party. The work, however, is a monument of assiduity and labour. It is methodically conducted, and upon the whole is an useful, though sometimes a fallacious, guide in the chronological history of the events that happened under the Roman emperors. The style, though not pure and elegant, is generally perspicuous. Amongst the critics and censurers of this work, we may reckon both protestants and catholics. The learned Isaac Casaubon undertook a refutation of the Annals of Baronius, in a work intitled “*Exercitationes, &c.*” and though he closed it with the 34th year of the Christian æra, he pointed out a great number of palpable errors into which the Roman annalist had fallen during that short interval. Even the Roman catholic literati acknowledge the inaccuracies and faults of Baronius; and hence Pagi, Norris, and Tillemont, &c. have been employed to correct them. Accordingly, a new edition of these “*Annals*” was published at Lucca, in 1733, with the corrections of these reviewers at the foot of every page. The original work was first printed at Rome, and soon after at Antwerp by Plantin; and editions have also been published at Cologne and Venice. Abridgments of it have also been published by several persons. About two years before the appearance of the “*Annals*,” Baronius published a kind of prelude, intitled, “*Martyrologium Romanum restitutum*,” &c. or “*Notes on the Roman Martyrology*,” folio, 1586; and afterwards often printed with corrections. Mosheim's *Ecc. Hist.* vol. iv. p. 206. Cave's *Hist. Lit. tom. i. Prolegomena*, p. 6, &c.

BARONIUS, Theodore, of Cremona, in Italy, published in 1609, in 4to, “*De operationis medicinali triplici læsione et curatione, libri duo, in quibus morbi omnes renum, et vesicæ, ex Galeni præsertim mente, pertractantur*.” He was a strenuous defender of the doctrines of Galen, with whom, he is said to have declared, it is more creditable to err, than to reason right on any other system: but he has in some points left his guide. He recommends the use of cantharides internally in affections of the kidneys and bladder, a practice it is probable Greenfield learned from him: he also injected medicated liquors into the bladder, with the view of facilitating the egress of calculi, or of dissolving them. *Hall. Bib. Med.*

BARONIUS, Vincentius, a celebrated Italian physician, published in 1636, 4to. "De Peripneumonia, anno 1633, et alibi temporibus, Fluminum, aliarque regiones, populariter insidente, ac a nemine haecum observata, libri duo, Forohis," a work of considerable merit, giving a particular account of the disease, and of the method found most successful in combating it, with the appearances observed on dissecting the bodies of those who died of the complaint. The epidemic was attended with fever, pain in the chest, cough, difficulty of breathing, and an inextinguishable thirst. Those who expectorated freely, early in the complaint, particularly if they had been plentifully bled, usually, he says, recovered. The lungs of those who died were universally inflamed; sometimes, but not always, the pleury was also affected; and in some of the subjects, serum was found effused in the cavity of the thorax. The disease was not, he says, contagious. Haller. Bib. Med.

BARONTHALIA, in *Geography*. See **LASSA**.

BARONY, BARONIA, or BARONAGIUM, the lordship or fee of a baron, either temporal or spiritual; in which sense barony amounts to the same with what is otherwise called *honour*.

A barony may be considered as a lordship held by some service in chief of the king, coinciding with what is otherwise called *grand serjeanty*.

Baronies, in their first creation, moved from the king himself, the chief lord of the whole realm, and could be holden immediately of no other lord. For example, the king enfeoffed a man of a great seigneurie in land, to hold to the person enfeoffed and his heirs, of the king and his heirs, by baronial service, to wit, by the service of twenty, forty, sixty knights, or of such other number of knights, either more or fewer, as the king by his enfeoffment limited or appointed. In the ages next after the Conquest, when a great lord was enfeoffed by the king of a large seigneurie, such seigneurie was called a *barony*, but more commonly an *honour*: as the honour of Gloucester, the honour of Wallingford, the honour of Lancaster, the honour of Richmond, and the like. There were in England certain honours, which were often called by Norman or other foreign names; that is to say, sometimes by the English, and sometimes by the foreign name. This happened when the same person was lord of an honour in Normandy or some other foreign country, and also of an honour in England. For example, William de Forz, de Force, or de Fortibus, was lord of the honour of Albemarle in Normandy, he was also lord of two honours in England, to wit, the honour of Holderness, and the honour of Skipton in Craven. These honours in England were sometimes called by the Norman name, the honour of Albemarle, or the honour of the earl of Albemarle. In like manner, the earl of Britannie was lord of the honour of Britannie in France, and also of the honour of Richmond in England: the honour of Richmond was sometimes called by the foreign name, the honour of Britannie, or the honour of the earl of Britannie. This serveth to explain the terms, honour of Albemarle in England, *honor Alenmarlia*, or *comitis Alenmarlie in Anglia*; *honor Britannie*, or *comitis Britannie in Anglia*, the honour of Britannie, or the earl of Britannie in England. Not that Albemarle or Britannie were in England, but that the same person respectively was lord of each of the said honours abroad, and of each of the said honours in England. The baronies belonging to bishops are by some called *regalia*, as being held solely on the king's liberality. These do not consist in one barony alone, but in many; for, *tot erant baronia, quot majora presidia*. See **BISHOP**.

A barony, according to Bracton, is a right indivisible;

wherefore, if an inheritance be to be divided among the coparceners, though some capital messuages may be divided, yet if the capital messuage be the head of a county or barony, it may not be parcelled; and the reason is, lest by this division many of the rights of counties and baronies by degrees come to nothing, to the prejudice of the realm, which is said to be composed of counties and baronies.

BARONY is in Ireland the name of the divisions of the counties, answering to the English hundreds. According to these, county taxes are assessed; and they are often noticed in the proceedings of parliament. The number of baronies in Ireland is 252.

BARONYCHIA, in *Botany*. See **ASPLENIUM ruta muraria**.

BAROPHTIAS, in *Ancient Geography*, a town of Persia proper, according to Zohnius.

BAROPTIS, or BAROPTINUS LAPIS, in *Natural History*, a name given by the ancient naturalists to a species of stone, supposed to have wonderful virtues against venomous bites, externally applied. Pliny has left us but a very short description of it: he says, it was black in colour, but variegated with large spots of red and white.

BAROS, in *Ancient Geography*, a place of Asia, in Mesopotamia.

BAROSCOPE, derived from *βαρα*, *onus*, and *σκοπος*, *visio*, a machine contrived to shew the alteration in the weight of the atmosphere. See **BAROMETER**.

BAROSELENITE of Kirwan, in *Minerology*. See **PONDROUS SPAR**.

BAROVSK, in *Geography*, a district of the government of Kaluga in Russia, situate on the river Protva, which falls into the Oeca.

BAROWECZ, a town of Poland, in the palatinate of Lublin, 26 miles north of Lublin.

BAROZZI, JAMES, in *Biography*. See **VIGNOLA**.

BARPANA, in *Ancient Geography*, *Cerbelli*, an island of Italy, in the Tuscan sea, according to Piny.

BARQUES POINT, in *Geography*, a cape on the north-east of Sagana bay in lake Huron.

BARQUETTE, or BARCHETTA, in the Mediterranean, denotes a lesser sort of barks, used for the service of galleys much as boats and shallops are for other ships, as to fetch provisions, water, carry persons ashore, and the like.

BARR. See **BAR**.

BAR, BARRA, or BARRO, in *Commerce*, denotes a Portuguese long measure, used in the mensuration of cloths, stuffs, and the like; six whereof are equivalent to ten *cavidos* or *cabidos*; each *cavido* equal to $\frac{2}{3}$ of a Paris ell.

The Spanish *Barra* is the same with the yard of Seville.

BARR of Valencia is equal to $\frac{3}{4}$ of the Paris ell; the barr of Castile is equal to $\frac{2}{3}$ of the Paris ell; and the barr of Aragon is equal to $\frac{1}{2}$ of the Paris ell. Savar. Dict. Com. p. 273. See **MEASURE**.

BARR is also used by the Portuguese in the East Indies for a weight, more frequently called **BARAR**.

BARR or Bar, in *Geography*, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Benfelden; 7 miles W.N.W. of Benfelden.

BARR-DICE, a species of false dice so formed as that they will not easily lie on certain sides, or turn up certain points. *Barr-Dice* stand opposed to flat dice, which come up on certain points oftener than they should do.

BARRA, in *Geography*, an island of Africa, in the mouth of the river Gambia.

BARRA or Bar, a kingdom of Africa, near the river Gambia, extending on the borders of it about 20 leagues.

BARRA or Barway, one of the western islands annexed to Inver-

Invernesshire, in Scotland, has remained for many ages in the possession of the Macneils of Barray or Barra. It is well stored with black cattle, and fruitful in barley and oats. The manufacture of kelp is carried on with considerable profit in this island. Cod and ling are caught on the east coast in great quantities; and the fishermen also take some dry-fish, the oil of which they burn in their lamps, and they sell that which is not consumed by themselves at 7d. or 8d. the Scots pint. Shell-fish, and particularly cockles, are abundant: the cockles are found in the great sand at the north end of the island, and afford a very plentiful supply of subsistence to the inhabitants. The fishery, however, has been much neglected. This island is somewhat hilly; in extent it is nearly 8 miles long and 4 broad; it is populous, notwithstanding the late emigrations to America, and it is said to contain about 1604 inhabitants. The natives are in general Roman Catholics. It is situated nearly south from South Wilt, and almost communicates with Benbecula at low water, and on this account they are both comprehended sometimes under the name of Long island. Its coast on the west side is low and flat, but on the east side steep and irregular. N. lat. 57° 2'. W. long. 7° 30'.

BARRA Lough, a lake of Ireland, in the county of Donegal, through which the river Guibarra flows: 20 miles north of Donegal.

BARRABA. See **BARABA**.

BARRABOA, a town of Africa, in the country of Magadoxa.

BARRAC Lough, a lake of Ireland, in the county of Monaghan, on the western side of which is situated the town of Castle Blayney.

BARRACKS. See **BARACKS**.

BARRACOL, in *Ichthyology*, a name given by Artedi, from the Venetians, to express the species of ray-fish, called by Bellonius and Gesner *miralelus*, and by others *raia oculata lucia*.

The specific name of Artedi carries in it a much better character of the fish; he calls it the *ray*, with a smooth back and belly, and with the eyes surrounded with a series of spines, and three other rows of them on the tail.

BARRA-COSDA, in *Geography*, a town of Africa, in the country of Nigritia, seated on the river Gambia.

BARRACOO, or as the sailors call it, **BEREA**, or **BER-KU**, lies on the west coast of Africa, 6 or 7 leagues W.S.W. from Acra, and is known at sea by two very high mountains behind it, one of which is double at the top with a saddle, and they are covered with trees. Some rocks lie off in the sea just before it, and form a kind of haven.

BARRACOPE, lies on the west coast of Africa, seven leagues E.S.E. from St. Mary's, and at the same distance from the river Junk in the same direction on the other hand. This coast abounds with negroe towns, and also with trees and water.

BARRAD, a town of Arabia, 40 miles south-east of Saade.

BARRADY. See **BARADY**.

BARRAGAN, or **BARRACAN**, in *Commerce*, a kind of stuff belonging to the class of camblets, only of a grain much coarser than the rest, manufactured in divers parts of France and Flanders, chiefly at Abbeville, Amiens, Rouen, and Lille, and now in England.

The word is barbarous Latin, formed, as some suppose, from *barra*, q. d. *barrarum formam referens*. Du-Cange. The chief use of *barragans*, called also by the French *bou-racans*, is for furtouts, or upper garments against the rain, being, when good, of so close a grain, that the water will not leak through, but only run upon them.

VOL. III.

For the wool, its thread is single, twisted, and fine spun; that of the warp is double or triple, i. e. composed of two or three threads well twisted together. The usual matter it is made of, is wool; though there are some made at Rouen, where the warp is hemp, and the wool wool. Some *barragans*, again, are made of wool, dyed before it comes to the loom; others are woven white, and dyed afterwards, red, black, blue, brown, &c. They are not fulled, but only boiled two or three times in fair water, when they come from the loom; then calendered to make them smooth and even; and lastly, made into rolls called pieces of *barragan*.

BARRAL, PETER, in *Biography*, a French abbé, was born at Grenoble, and removing to Paris, at an early period of his life, took up the office of a school-master. He died there July 21, 1772. His chief literary work is a "Dictionnaire historique, littéraire, et critique des Hommes celebres," 6 vols. 8vo. 1759. It was nicknamed the Martyrology of Jansenism, compiled by a convulsionnaire. Although this work betrays too much of the spirit of party, the articles of learned authors, poets, orators, and literary men, are generally compiled with judgment and taste. Barral has also published an abridgement of the letters of madame de Sevigné in 12mo. under the title of "Sevigniana," and a valuable abridgement of the "Dictionnaire des Antiquités Romaines," by Pitiscus, in 2 vols. 8vo. He was a man of erudition, and of lively conversation; and the style of his writings is vigorous and manly, though sometimes negligent and incorrect. Biog. Dict.

BARRA-MAHAL, or **BARRA-MAUL**, denoting the "twelve places," in *Geography*, a valley called also Vaniambaddy, in the peninsula of India, containing 12 fortresses of some note: viz. Kiltmagheri, Jegadivy, Candely, Congoonda, Vaniambaddy, Mahrauzegar, Cochingur, Cooturagur, Bazingur, Tripatore, Tadcul, and Gigangurry.

BARRAN, a town of France, in the department of the Gers, and chief place of a canton in the district of Auch, containing about 700 inhabitants; 2 leagues W.S.W. of Auch.

BARRANCA, a town of South America, in Peru, with a harbour, in the Pacific ocean. The jurisdiction of Guaura begins at this town. The number of houses does not exceed 60 or 70, and yet the town is populous, many of its inhabitants being Spaniards. Near the town is a river of the same name, which divides into three branches. The port is to leeward of a small low point. S. lat. 13° 30'. W. long. 42° 4'.

BARRARDA, in *Ancient Geography*, a town of Asia, in Paropamisus. Ptolemy.

BARRATI, *barred*, an appellation given to the Carmelites after they were obliged to lay aside the white cap, and wear cowls striped black and white.

BARRATRY is used for bribery or corruption in a judge giving a false sentence for money.

BARRATRY, in *Commerce*. See **BARATRY**.

This term comprehends any species of fraud, knavery, deceit, or cheating, committed by the master or mariners of a ship, by which the owners sustain an injury; as by running away with the ship, wilfully carrying her out of the course prescribed by the owners, sinking or deserting her, embezzling the cargo, smuggling, or any other offence, whereby the ship or cargo may be subject to arrest, detention, loss, or forfeiture. Hence, in cases of insurance, if the breach assigned in the declaration on a policy was the loss of the ship "by the fraud and negligence of the master," this was determined to be a sufficient averment of a loss by barratry. At Amsterdam, Hamburg, Middleburgh, and some other maritime towns, insurers are, by positive law,

made responsible for the barratry of the master and mariners. With us the law permits the owner of the ship to be insured against the misconduct of the captain and crew, though they are his own agents, and the persons of his own choice. If the captain be the insured, no agreement on the part of the insurers can make them liable for barratry committed by himself; but they may be liable, in such case, for the barratry of the sailors, in which he has no part. With us no fault of the master or mariners amounts to barratry, unless it proceed from an intention to defraud the owners of the ship. Therefore if the master from ignorance, unskilfulness, or from any motive which is not fraudulent, depart from the proper course of the voyage; this will be a deviation which will avoid the policy, but it will not amount to barratry. In France if by the policy the insured be protected against the barratry of the master, the underwriters are answerable for the misconduct of the mariners also; because the term *patron* comprehends all the persons on board who are in the ship's pay. Our policies are more explicit, and distinctly specify barratry of the master and mariners. Hence it has been concluded, that with us, as in France, the mariners may commit barratry, without the concurrence of the master, or against his will. Nevertheless it has been held by lord C. J. Lee, as *Nisi Prius*, that a deviation to which the master was compelled by a very daring act of violence and disobedience on the part of the seamen, did not amount to barratry, because the ship was not actually run away with in order to defraud the owners. The insurers, therefore, were held to be answerable, and the plaintiff had a verdict. This learned judge seems to have thought, that nothing short of running away with the ship, with intent to defraud the owners amounted to barratry; and yet in another case, the conduct of the master was held to be barratry, though certainly much more venial than that of the sailors in the former case. Hence it has been inferred, that though the captain conceive that what he does is for the benefit of the owners, yet if it be contrary to his duty to them, it is barratry. An owner himself cannot commit barratry; neither can it be committed against the owner, with his consent. If the master of the ship be also the owner, he cannot commit barratry, because he cannot commit a fraud against himself. Although it be a maxim in law, that fraud shall never be presumed, but must be strictly proved; and it is a rule in questions of insurance, that he who charges barratry must substantiate it by conclusive evidence; yet a case has occurred, in which it was determined, that proof of the master's having carried the ship out of the regular course of the voyage for fraudulent purposes of his own is *prima facie* sufficient to entitle the plaintiff to recover, without shewing negatively that he was not the owner, or that any other person was the owner, or that this was not done with the owner's consent. Though the words "in any lawful trade," be inserted in the policy, still the insurer is liable, if the captain commit barratry by smuggling on his own account. It appears, that if a loss do not happen within the time prescribed by the policy for the duration of the risk, the insurer will not be liable for it, though it be the undoubted consequence of the act of barratry.

The offence of barratry, in itself so mischievous, and so injurious to commerce, is punishable as a public offence, according to the guilt of the offender, by every commercial state in Europe. In France, any fraud practised by the master or mariners, with or without the privity of the owners, and frauds committed by the owners themselves, are accounted barratry, and very severely punished. The captain of a ship was sentenced to the galleys for life, for signing false bills of lading in order to change the voyage

and carry away the goods; and the owner, who was convicted of being an accomplice in this crime, and of robbery in causing the ship to be carried to a wrong port, and converting the goods on board to his own use, was sentenced to the galleys for five years. With us the stat. 1 Ann. st. 2. c. 9. § 4 & 5. makes it felony to destroy any ship to the prejudice of the owners of the ship or goods on board; and takes away the benefit of clergy from such offences, committed on the high seas. By stat. 4 Geo. I. c. 12. § 3. if any owner, captain, master, mariner, or other officer of any ship, shall wilfully call away, burn, or otherwise destroy the ship of which he is owner, or to which he belongs, or in any manner direct or procure the same to be done, to the prejudice of the person or persons that shall underwrite any policy of insurance thereon, or of any merchant that shall load goods thereon, he shall suffer death: and the stat. 11 Geo. I. c. 29. takes away clergy from such offenders in all cases. Marshall's Treatise on the law of Insurance, vol. ii. chap. 13. See PIRATE.

BARRATRY is also used in the law of England for the offence of stirring up frequent suits and quarrels among his majesty's subjects. The term, however, is of foreign origin; and in Italy and other countries seems ordinarily to have been applied to the traffic of ecclesiastical benefices; but was afterwards used in a more general sense, as applicable to all corrupt buying and selling of justice. In Scotland it signified the corrupt purchasing of benefices or offices of collection, from the see of Rome, by persons who left the realm for that purpose: a practice, which had become frequent, and was in various respects injurious to the realm; as a means of carrying money out of it, without any return of value, as prejudicial to the right of patronage in the king or others, and to the free elections of the monks in the monasteries, both which the pope by prevention pretended to exclude, and as contributing to raise the rate of taxation upon benefices, by the false accounts which those suitors for the office of collector carried to the pope.

BARRE. See BAR.

BARRE, *Lewis-François Joseph De La*, in *Biography*, was born at Tournay in 1688, and educated at Paris; where he applied to the study of the ancient languages and to the collation of MSS with such assiduity, that he was recommended to Anselm Banduri, the learned Benedictine, as a proper assistant in his antiquarian researches. In consequence of their joint labours, they published the "Imperium Orientale," and the collection of the medals of the Roman emperors from Decius. For these services Barre had a pension from the grand duke of Tuscany. He also gave a new edition of the "Spicilegium" of Luke d'Achery, in 3 vols. fol. printed at Paris in 1723. He had also a considerable share in the new edition of "Moreri's Dictionary" of 1725. In 1727, he was elected a member of the Academy of Inscriptions, the memoirs of which he enriched by several valuable papers, historical, chronological, geographical, and miscellaneous. He also published, in 1729, in one vol. 4to. "Memoirs for the History of France and Burgundy," known under the title of the "Journal of Charles VI." Besides other publications of a less important nature, he finished more than 100 select articles of a new and ample dictionary of Greek and Roman antiquities; but he was prevented by death, in 1730, from completing his undertaking. Moreri.

BARRE, *Joseph*, a learned historian, was born in 1692; and entering into the church, he became first a regular canon of St. Genevieve, and afterwards chancellor of the university of Paris. He was distinguished for piety and erudition, and for his industry as a writer. His principal works

works are "Vindiciae librorum deutero-canoniconum Veteris Testamenti," 1730, 12mo.; "A General History of Germany," 11 vols. 4to. 1748; "The Life of Marshal de Fabert," 2 vols. 12mo. 1752; and the "History of the Laws and Tribunals of Justice," 4to. 1756. *Nouv. Dict. Histor.*

BARRE, in *Geography*, a town of France, in the department of the Lozerre, and chief place of a canton in the district of Florac, 2 leagues S. of Florac, and $6\frac{1}{2}$ W.N.W. of Alais.

BARRE, *La*, a town of France, in the department of the Eure, and chief place of a canton in the district of Bernay, 3 leagues S. E. of Bernay, and $6\frac{1}{2}$ W.S.W. of Evreux.

BARRE, a township of America, in Worcester county, and state of Massachusetts, containing 1613 inhabitants; 24 miles N.W. of Worcester, and 66 W. of Boston; deriving its name from that of the late Col. Barré, a British senator, and an advocate for the cause of America, in the war which terminated in the separation of the two countries. The township has good pastures, fattens a multitude of cattle, and produces more butter and cheese for the market than any other of the same extent in the state.

BARRE is also a township of Huntingdon county in Pennsylvania.

BARREA, a circle or district of Hindostan, in the country of Guzerat.

BARREE BAY. See **BAXA**.

BARREGES LES BAINS. See **BAREGES**.

BARREL, an oblong vessel, of a spheroidal, or rather a cylindrical figure, used for the holding divers sorts of goods both liquid and dry.

Barrels are of divers uses in *Artillery*, as for powder, small shot, flints, sulphur, salt-petre, rosin, pitch, quick-match, and many other things.

Barrels filled with earth serve to make a parapet to cover the men, like gabions and canvas bags.

Fire-barrels are casks of divers capacities, filled with bombs, grenades, fire-pots mixed with great quantities of tow staked in petrol, turpentine, pitch, &c. used by the besieged to defend breaches. These are sometimes also called *thundering barrels*, being to be rolled down on the enemy on their entering the breach.

BARREL is also used for a certain quantity, or weight of several merchandizes; which is various as the commodities vary.

The English barrel, wine measure, contains the eighth part of a tun, the fourth part of a pipe, and the moiety of a hoghead, that is, thirty-one gallons and a half; of beer it contains thirty-six gallons, and of ale thirty-two gallons.

The barrel of beer, vinegar, or liquor preparing for vinegar, is to contain 34 gallons, according to the standard of the ale quart. 10 and 11 W. III. cap. 21.

The barrel of herrings is to contain 32 gallons, wine measure; being about 28 gallons, old standard: usually amounting to about 1000 full herrings, 13 Eliz. cap. 11.

The barrel of salmon is to contain 42 gallons, 5 G. cap. 18.—And the barrel of eels the same, 22 Ed. IV. cap. 2.

The barrel of soap is to contain 256 pounds, 10 A. cap. 19.

A barrel of Essex butter weighs 106 pounds, and of Suffolk butter 256 pounds.

In some parts of Ireland, particularly in the city of Cork, coals and salt are measured by the barrel. The barrel used to contain 7 bushels Winchester, but that lately introduced for coal is, according to law, 4 bushels; i. e. 40 English, or 50 Irish gallons. Salt is still measured in the barrel of 7

bushels, but *strike* measure; whereas the coal was sold by *heap* measure, which put it into the power of the measurer to cheat either the seller or buyer at pleasure. The abuse was found to great that this kind of measurement has been abolished.

The barrel or barille of Florence is a liquid measure containing 20 *fiacques*, flasks, or one-third of a *flar* or *Itaio*.

The barrel, *barrique*, of Paris, contains 210 pints, or 26 *septiers* and a half; four *barriques* make three *nuids*, or one *tun*.

BARREL, in *Anatomy*, denotes a pretty large cavity situated behind the drum of the ear, lined with a membrane in which there are several veins and arteries. It is said to be full of a purulent matter in children; and in its cavity there are four small bones; viz. the *malleolus*, the *incus*, the *stapes*, and the *os orbiculare*.

BARREL of a Clock, in *Mechanics*, is a cylindrical part, about which the string is wound. And the barrel of a watch is the cylinder which contains the spring, and about which the chain coils.

BARREL of a Gun, Pistol, &c. is the cylindrical tube through which the ball is discharged.

BARREL of a Jack, is the cylindrical part whereon the line is wound.

BARREL of a Pump, is the wooden tube which makes the body of the engine, and wherein the piston moves.

BARRELET, in *Heraldry*. See **BARRULET**.

BARRELIER, **JAMES**, in *Biography*, a Dominican monk, was born at Paris, in 1606, of a noble family. Having received a liberal education, and being well skilled in Latin, Greek, and several modern languages, he applied himself to the study of medicine; but entering among the Dominicans, in 1635, he now confined himself to acquiring a knowledge of plants. With this view, he embraced an opportunity offered him, of accompanying the head or general of the Jacobins, as an assistant, with whom he travelled over a great part of France and Spain, collecting every where whatever rare plants could be found, of which he procured drawings to be made. At the end of 23 years, a great part of which was spent in Italy, he returned to Paris. He now applied himself in arranging the plants he had collected, proposing to publish accounts and delineations of them, in the manner adopted by *Tournefort*, and had proceeded so far as to get engravings of 1324 of the plants finished, when he died of asthma in 1672. His manuscripts, drawings, and plates, were deposited, after his death, in the library of the Jacobins at Paris, where they remained until the year 1714, when *Antonine Jussieu* undertook to publish them, under the title of "*Plantæ per Galliam, Hispaniam, et Italiam observatæ, et iconibus æneis exhibitæ, a R. P. Jaco. Barreliero, opus posthumum;*" Parisiis, 2 vol. fol. The engravings are on a small scale, frequently borrowed from other works, *Haller* says, and many of them repetitions of the same plants. Many of them, however, he adds, are new, and of scarce and valuable plants, which entitles these volumes to a place in all botanical libraries. *Haller. Bib. Botan. Eloy. Dict. Hist.*

BARRELLING, the art of putting up certain commodities in casks or barrels.

Gun-powder for the land service is often barrelled double, the barrel it is put in being inclosed in another barrel, partly to prevent the powder catching moisture in the subterraneous places it is kept in, and partly to enable it the better to bear the motion and jolting of carriages, when it is to be conveyed to another place.

BARRELLING of Herrings, imports the cutting off their heads as they are thrown into the buss, and afterwards pill-

ing out the guts, salting them, and putting them up in barrels. There are two sorts of barrelled herrings; one wherein they are laid orderly, layer over layer, called by some packed herrings; the other wherein they are thrown at random, called herring in wrack.

The difference arises thus: as fast as the fishermen catch the herrings, they throw them on the deck of the vessel; where having gutted and salted them, they throw them at random into the barrel, to be carried home: this is the herring in wrack.

When arrived ashore, they take the fish out of these barrels, cast them into a tub, and salting them anew, range them handomely in their barrels again, laying salt over them, to preserve them; these are the packed herrings. And it is in this state they are usually sold.

BARRELL'S SOUND, in *Geography*, lies on the N.W. coast of America, and is called by the natives *Conget-hoi-toi*. It is situated about 6 leagues from the southern extremity of Washington or Charlotte islands, in a N.W. direction, about N. lat. 52°. W. long. 131°. It has two inlets, one on the east, the other on the west side of the island; the latter is the best, the other is dangerous. The shores are of a craggy black rock; and the banks are lined with trees of various kinds; as pines, spruce, hemlock, alder, &c. This sound was first visited by Capt. Gray in the Washington in 1789, and derived its name from Joseph Barrell Esq. of Charlestown.

BARRELS, the name given to rocks near the south coast of the county of Wexford, in the Irish sea, 5 miles S.W. of Carnfore point.—Also, to rocks near the south coast of Ireland, in Courtmaschery bay.

BARREME, a town of France, in the department of the Lower Alps, and chief place of a canton in the district of Digne, 10 miles S.S.E. of Digne.

BARREN, is a term of Saxon origin, and means, applied to animals or vegetables, unfruitful, sterile, incapable of producing or propagating its like. Land is called barren, on which no plants, fit for the sustenance or nourishment of man or animals, will grow. Metaphorically applied to the human mind, it means dull, stupid, uninventive.

In man and animals barrenness is usually occasioned by some defect in the organs of generation. Both sexes are liable to this deficiency; but it is thought to be more incident to the female than the male. It is remarkable, that hybrid animals, as the mule, are incapable of propagating their like. See **HYBRIDS**.

Barrenness may also be occasioned by general debility, or ill health; and yet women in nearly the last stage of consumption, are not unfrequently found to conceive, to carry the fruit to its full term, and at length produce it in a sound and healthy state; the progress of the consumption being stopped during the time of utero-gestation. See **CONSUMPTION**.

Defects, occasioning barrenness or sterility, are either external or internal. The most usual external deficiency in men, is, a penis too short, slender, or feeble. This state of that organ is often attended with a degree of curvature, the end being held down by a strong bridle. In these cases, the orifice of the urethra, instead of being at the end is in the under part of the penis, within half an inch of its extremity; whence there is not only considerable difficulty in introducing it into the vagina of the female, but in the venereal orgasm, the semen, instead of being thrown forwards towards the os uteri, is ejected backwards, and so lost.

In the female, straitness of the vagina, or cohesion of its sides, preventing the intromission of the male organ, may

occasion barrenness. These defects may sometimes be remedied by appropriate operations. (See **VAGINA**, *Diseases of*.) The same effect, a straitness of the vagina, may be occasioned by scirrhus affections of its sides (see as above).

But a more common case is an expansion of the membrane called the hymen, shutting up the entrance of the vagina, and only leaving, at the anterior part, a small hole for the passage of the urine. Midwives are therefore cautioned, on the birth of female children, to examine whether the passage into the vagina be open, and if they find it covered by a thin membrane, to separate it with their nails, and to inspect the part for a few subsequent days, that it may not coalesce again. If this caution has been neglected, the membrane, which at the birth of the child is so tender as to yield to the slightest force, becomes, in a few years, thick, firm, and fleshy, and can only then be divided by a painful and troublesome operation. See **HYMEN**, *Imperforated*.

The vagina is also sometimes found divided into two canals or passages, by a strong, fleshy, membranous partition, running its whole length, or nearly so, rendering the introduction of the male organ difficult or impracticable. These two passages sometimes communicate at the upper end, and receive a single os uteri; at others, they continue separate, terminating, or each of them leading to an os uteri; the uterus having, in these cases, two cavities, or there being two uteri. (See the articles **VAGINA**, and **UTERUS**.) These, however, may be considered as causes rendering impregnation difficult, but not impossible. More certain and inevitable causes of barrenness in women are, imperviousness, scirrhus, or other diseases of the os uteri, Fallopian tubes, or of the ovaries, which are generally incurable.

Debility, occasioning barrenness in men particularly, is most commonly caused by the too early, or too frequent, and inordinate use of venery, by manstrupation, or self-pollution (see **ONANISM**), by repeated attacks of gonorrhœa or syphilis; by gleans, and by frequent and long continued courses of mercury. For the cure of those complaints, see **GONORRHOEA**, **LUES VENEREA**, **GLEETS**; see also **CONCEPTION**, *Causes impeding*.

BARREN Corn, in *Agriculture*, a term applied to a distemper in corn, in which the ears of such kinds as are affected, as wheat and rye, which are the most subject to it, are long, lean, and white; in some, the stamina, or small threads in the middle of the flower, are dry, transparent, and horned; the female organs are small, whiter, and less velvety than in healthy ears; in others, the filaments are swelled, the apices or knobs on the tops of the stamina void of dust or farina, and the stigma badly unfolded. The stigmata of all the blossoms of an ear are sometimes dried and parched, and at other times the apices are much swelled out. This distemper of corn has been ascribed to various causes; such as its too sudden growth, the influence of frost or of hot gleams of sunshine after heavy showers; and sometimes, though rarely, to insects. Count Ginnani imputes it to the faultiness of the soil; and he recommends particular attention to the amendment of it by such means as are best suited to its nature; and he also directs to change the seed every year.

BARREN Earth, a term given by some writers to particular sterile soils, and also to the under stratum of earth, or that which lies immediately below the bed of mould, which is most frequently turned up and cultivated for the nourishment and support of plants. The idea of the under strata of soils being improper for the growth and support of plants seems to have originated in error, as it is now well known that every kind of earth, whether placed near the surface

or at a considerable depth below it, is capable of affording the support of plants, when well broken down and rendered sufficiently mellow by ploughing, and the influence of the atmosphere.

BARREN Lands, are such as either naturally, or for want of proper tillage and cultivation, do not on being sown produce good crops or such as are sufficient for repaying the expences of the cultivator.

BARREN Money, in the *Civil Law*, denotes that which is not put out to interest.

BARREN Soils, in *Agriculture*, are those which, from the nature of their constituent ingredients, are incapable of affording full crops. The materials which enter into the composition of such soils are, according to Mr. Kirwan, filix, argill, and calx, in the following proportions.

Silex from	42	to	88
Argill	20		30
Calx	4		20

From which he concludes the troy pound to contain, allowing 120 grains for water, of

Silex from	2368	to	4963
Argill	1128		1622
Calx	225		600

The specific gravity in such soils has not been fully ascertained, but the same writer supposes it to be either much above or greatly below that of other kinds, according as they are too close or too open and porous. That of barren sandy land was found by M. Fabroni to be 2.21. See **SOIL**.

BARREN Springs, in *Rural Economy*, such springs as are injurious to lands when suffered to flow or run over them. Waters that flow from coal mines, or through mineral strata, have frequently been observed to have this pernicious quality; and such also as contain either aluminous or ferruginous materials in a state of solution in them.

BARREN Flowers or *Florets*, called also *abortive*, in *Botany*, are such as produce no perfect seeds. The barren flowers are such as have stamens, but no pistils; and they are also called male flowers. Flowers which have only pistils, are sometimes barren, owing to the absence of other flowers, which bear the stamens. In the umbelliferous flowers, it is not uncommon to have several of the florets barren, though they are furnished both with stamens and pistils; perhaps owing to some imperfection in the pistils; but future observations must determine this matter.

BARREN Creek, in *Geography*, rises in the N.W. corner of Delaware state in America, runs about 9 miles S.W. and discharges itself into Nanticoke river. A triangular tract of land in the N. part of Somerset county, Maryland, is inclosed between this creek on the S., Delaware states E., and Nanticoke river on the W. and N.W.

BARREN Island, a small isle in Chesapeake bay, N.E. from the mouth of Patuxent river, which is separated from Hooper's island by a narrow channel on the east.

BARREN Island is also an island in the East Indian ocean, about 6 leagues in circumference. The whole island has a singular and volcanic appearance; and there is upon it a violent volcano, which emits immense volumes of smoke, and showers of red-hot stones, some of which weigh 3 or 4 tons, and are thrown some hundred yards beyond the foot of the cone. The base of the cone is the lowest part of the island, and very little higher than the level of the sea. It rises with an acclivity of 32° 17', to the height of 1800 feet nearly, which is also the elevation of the other parts of the island. Those parts of the island that are distant from the volcano, are thinly covered with withered shrubs and blasted trees. It is situated in N. lat. 12° 15', and 15 leagues to

the east of the easternmost cluster of the Andaman islands, and may be seen at the distance of 12 leagues in clear weather. At a quarter of a mile from the shore, there is no ground with 150 fathoms of line. Asiatic Researches, vol. iv. p. 395, &c.

BARREN Isles, lie on the N.W. coast of America, at the entrance of Cook's inlet. These isles, situated in N. lat. 58° 48', and E. long. 208° 30', and cape Elizabeth, situated in N. lat. 59° 9', and E. long. 208° 53', according to Vancouver's chart, form a channel into Cook's inlet.

BARREN River, a name given to each of the S.E. branches of Green river, in Kentucky; between which lies *Blue Spring*.

BARRENESS. See **STERILITY**.

BARRENWORT, in *Botany*. See **EPIMEDIUM**.

BARREONE, in *Geography*, a river of Piedmont, which runs into the Vefubia, near St. Martin, in the county of Tenda.

BARRERE, PETER, in *Biography*, professor of medicine, physician to the military hospital at Perpignan, his native country, resided three years at Cayenne, as botanist to the king of France, and employed himself in acquiring a distinct knowledge of the plants and animals indigenous to that country, of which he published accounts on his return. He died November 1st 1755. In 1741, he published "A Dissertation on the Causes of the Colour of the Skin in Negroes," which he thought was occasioned by the bile being in them blacker than in Europeans; and in 1746, "Observations on the Origin and Formation of figured Stones." But his principal works were, "Essai sur l'Histoire Naturelle de la France Equinoxiale," Paris, 1741, 12mo. in which he gives descriptions of the plants he had collected at Cayenne, many of them not before known, with their use in medicine, diet, &c. "Nouvelle Relation de la France Equinoxiale," Paris, 1743, 12mo.; republished, much improved, 1753; a continuation of the former work. In this he gives accounts of the method of cultivating the sugar-cane, of preparing sugar, coffee, aloes, and other valuable articles. In the "Histoire de l'Academie des Sciences," 1743, the method of cultivating rice; and in 1751, at Perpignan, 8vo. "Diverses Observations Anatomiques tirées des Ouvertures des Cadavres," containing some curious and instructive cases. Haller. Bib. Anat. et Botan. Eloy. Dict. Hist.

BARRERIA, in *Botany*, a tree so named from Peter Barrere, professor of medicine at Perpignan. Lin. g. Schreb. 1366. Scop. gen. 767. Poraqueiba. Aubl. Guian. Clafs, *Syngen. fia monogamia*. Gen. Char. *Cal.* perianth one-leafed, five-toothed, small. *Cor.* one-petalled, five-parted; parts oblong, acute, convex beneath, concave above, with a double pit; the superior ovate, bifid, the wedge-shaped one trifid; excavated for the reception of the stamens. *Stam.* filaments five, ascending linear, wider above, thick, triangular, bordered, curved; anthers erect, four-cornered, marginated, coalescing into the form of a mill-wheel; each, in the closed flower, answering, together with the filaments, to the pits of the two petals. *Pyl.* germ roundish; style short; stigma trifid.

Ess. Gen. Char. *Cal.* five-toothed, very small. *Cor.* five-parted; style short; stigma trifid.

Species, *B. guianensis*. Poraqueiba Guian. Aublet. Guian. t. 47. A tree forty or fifty feet high, and two feet and a half in diameter; the bark is ash-coloured, and the wood is hard and compact, of a reddish-brown colour. From the top proceed many branches, spreading in all directions; these send forth numerous twigs, with alternate, entire, smooth, firm, ovate leaves, ending in a long point; petioles short, convex beneath, channelled above. The flowers are in

in small axillary spikes, alternate, and almost sessile. A native of Guiana, in the extensive forests, near the banks of the river Sinemari, fifty leagues from its mouth. It flowers in November.

BARRET, GEORGE, in *Biography*, a painter of landscape, was born about the year 1732, in the city of Dublin, and exhibited at a very early age a strong disposition to the art in which he afterwards became eminent. Having gained a premium of 50*l.* offered by the Dublin Society for the best landscape in oil, he visited London in 1762, and in the second year after his arrival, obtained a similar prize from the Society for the encouragement of arts, &c. The establishment of the Royal Academy of Arts, &c. is said to have been much indebted to the efforts of Mr. Barret, who formed the plan, and became one of its members. He had two decided manners of painting, both with regard to colour and touch; his first was rather heavy in both, his latter was much lighter. Scarcely any painter equalled him in his knowledge or execution of the details of nature, the latter of which was particularly light, and well calculated to mark most decidedly the true characters of the various objects he represented, forest-trees in particular. His attention was chiefly directed to the true colour of English scenery, with regard to which he was very happy in his best works. His best pictures, in this country, executed according to his first manner, are to be found in the houses of the dukes of Buccleugh and Portland, &c. and those of his latter in his great work at Norbury Park in Surry, consisting of a large room, painted with a continued scene entirely round. The idea in general characterises the northern part of this country; and for composition, breadth of effect, truth of colour, and boldness of manner in the execution, has not been equalled by any modern painter. Barret also excelled in water-colours; and his drawings in chalk, Indian ink, and black-lead pencil, have great merit. In all his studies from nature he was very correct and minute. He also performed some slight but spirited etchings in landscapes. He died at Paddington near London in 1784. Pilkington and Strutt.

BARRET Bank, Great, in *Geography*, lies at the S. and S.E. end of the island of Oleron, on the coast of France, and forms the N.W. side of the Maumusson passage, as Point de Gardour, on the main land, forms the S.E. side.

BARRETRY. See **BARATRY**, and **BARRATRY**.

BARRETSTOWN, in *Geography*, a plantation in Hancock county, in the district of Maine, in North America, having 173 inhabitants.

BARRICADE, or **BARRICADO**, a military term for a fence or retrenchment, hastily made with vessels or baskets of earth, carts, trees, palisades, or the like, to preserve an army from the shot or assault of an enemy.

The most usual materials of barricades are pales, or stakes which are crossed with battens, and shod with iron at the feet; usually set up in passages or breaches, to keep back the horse as well as the foot.

BARRICADI, in the *Marine*, is a strong wooden rail, supported by pillars, and extending as a fence across the foremost part of the quarter-deck. In ships of war, the intervals between the pillars are commonly filled with cork, junks of old cable, or plated cordage. About a foot above the rail, there extends a double rope netting, supported by cranes of iron; and between the two parts of the netting are stuffed hammocks, filled with the seamen's bedding, to intercept small shot fired by swivel-guns and muskets, in time of battle.

BARRICOURT, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a cañton

in the district of Grandpré, 6 leagues S. of Sedan, and 3 N.E. of Grandpré.

BARRIER, in *Fortification*, a kind of fence made at a passage, retrenchment, gate, &c. to stop up the entry thereof. See **DEFENCE**. It is usually made of great flakes, about four or five feet high, placed at the distance of eight or ten feet from one another, with overthwart rafters; serving to stop either horse or foot that would rush in. In the middle is a moveable bar of wood, which opens and shuts at pleasure.

BARRIER Islands, in *Geography*, islands which lie off the river Thames, on the E. coast of New Zealand, and so called because they shelter it from the sea. They stretch from S.E. to N.W. for 10 leagues.

BARRIERS, corresponding to what the French call "jeu de barres," i. e. *palisera*, have been used to signify a martial exercise of men, armed, and fighting together with short swords, within certain rails or bars, by which they were inclosed from the spectators; now disused in this country.

BARRIERS, or **BARRIÈRES**, a name given, in the chief cities of France, and particularly at Paris, to the places where the custom-houses are established, and where the officers receive the duties of importation, according to the tariff settled by the king's council. They are called barriers because the passages, through which the carriages and merchandises liable to pay duties are to pass, are shut up with a wooden bar, which turns upon a hinge, and is opened and shut at the will of the custom-house officers.

There are at Paris sixty of these barriers, all placed at the entrance of the suburbs.

There are also *barrier towns*, or places of defence, on the frontiers of kingdoms.

BARRILE, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Basilicata; 7 miles W.S.W. of Venosa.

BARRING a Vein, in *Fariery*, now obsolete. See **BAR a Vein**.

BARRINGDIN, in *Geography*, a town of Africa, in the country of Barra.

BARRINGTON, JOHN SHUTE, LORD VISCOUNT BARRINGTON, in *Biography*, a learned nobleman, particularly distinguished by his attention to theological subjects, was the youngest son of Benjamin Shute, merchant, by a daughter of the famous Mr. Caryll, author of the commentary on Job, and descended from the ancient family of Shute in the county of Leicesters, of Roman extraction. He was born at Theobald's in Hertfordshire, in 1678, and received part of his education in the university of Utrecht. Upon his return to England he devoted himself to the study of the law in the Inner Temple; and in 1701 commenced his literary career as a writer, if we except his Latin oration "De Studio Philosophiæ conjungendo cum Studio Juris Romani," published at Utrecht in 1698; by an "Essay upon the Interests of England in respect to Protestants dissenting from the Established Church," 4to. to which class of British subjects he belonged. This was followed some time afterwards by another piece in 4to. intitled "The Rights of Protestant Dissenters, in two parts." At the age of 24, during the prosecution of his legal studies, he was appointed by the recommendation of lord Somers, to the arduous undertaking of engaging the Presbyterians of Scotland to favour the union of the two kingdoms, and in 1708 he was rewarded for his services by the office of commissioner of the customs. From this situation he was removed by the Tory administration of queen Anne, in 1711, on account of his avowed opposition to their principles and conduct. In the mean time his fortune was greatly improved by the bequest of two considerable

siderable estates; one left him by John Wildman, Esq. of Becket in Berkshire, who adopted him for his son after the Roman custom, and the other by Francis Barrington Esq. of Tofts, whose name and arms he assumed by act of parliament. On the accession of George I., he was chosen member of parliament for the town of Berwick upon Tweed; and in 1720, he was advanced by the king to an Irish peerage under the title of viscount Barrington of Ardglaf. In consequence of his unfortunate connection with the Harburgh company, as sub-governor under the prince of Wales, and of a lottery projected for defraying the expence of opening the port and a subscription for this purpose commenced during his absence, and in opposition to his opinion and advice, he underwent, in 1723, the very severe and unmerited censure of expulsion from the house of commons, which has been attributed to his lordship's opposition to the reigning minister, sir Robert Walpole. In 1725, he published in two volumes 8vo. his "Miscellanea Sacra, or a new method of considering so much of the history of the apostles, as is contained in scripture, in an abstract of their history, an abstract of that abstract, and four critical essays." This work traces, with judicious discrimination, the methods taken by the apostles, and first preachers of the gospel, for propagating Christianity, and explains the several gifts of the spirit by which they were enabled to discharge that office. Hence he deduced an argument for the truth of the Christian religion which is said to have staggered the fidelity of Mr. Anthony Collins. A second edition of this work, with large additions and corrections, was published by his son the present bishop of Durham, in 1770, 3 vols. 8vo. In the interval between its first publication and the death of the author in 1734, he reviewed, corrected, and enlarged it; and introduced such improvements, as add new force to his arguments and elucidation to his criticisms. In the same year, 1725, he also published "An Essay on the several Dispensations of God to Mankind, in the order, which they lie in the bible; or a short system of the religion of Nature and Scripture." He was also the author of several other tracts, chiefly on subjects connected with toleration in matters of religion, which he ably and zealously defended. He died in 1734, in the 56th year of his age. Lord Barrington had three daughters and six sons, five of whom have been advanced to high stations in the church, the law, the army, and the navy. His lordship was a disciple and friend of Mr. Locke, and adopted his sentiments as to the right and advantage of free inquiry, and the value of civil and religious liberty. As a theological writer, he discovers a high sense of the value of the sacred writings and great judgment in interpreting them; and he contributed in a very eminent degree to the diffusion of a spirit of liberal criticism. In his sentiments and disposition he was distinguished by his catholicism and moderation; and though he was a rational and steady dissentor, he was an occasional frequenter and communicant of the established church. Biog. Brit.

BARRINGTON, DAINES, the fourth son of lord Barrington, was educated for the profession of the law, and in 1757 was appointed a Welsh judge, and some time afterwards second justice of Chester. Although he never attained to distinguished eminence at the bar, he evinced his acquaintance with the law by a valuable publication, entitled, "Observations on the Statutes, chiefly the more ancient, from Magna Charta to 21 James I. c. 27; with an Appendix being a Proposal for new-modelling the Statutes," 4to. 1766. This work, which passed through five editions, has been respectfully quoted by many historians and constitutional antiquaries. In 1773, he published "Oronius," with

Alfred's Saxon version, and an English translation and notes of his own, which underwent a severe animal version from some of our critics. His "Tracts on the Probability of reaching the North Pole," 1775, 4to. were occasioned by the voyage of captain Phipps (now lord Mulgrave) towards the north pole in 1773. His other writings may be found in the Transactions of the Royal and Antiquarian Societies, of which he was an assiduous member, and of the latter vice-president. In several of these the author manifests some tendency towards singularity and paradox; nevertheless they indicate both diligence and extent of research, and evince his talents as a naturalist and antiquarian. Many of his tracts were collected by himself in a 4to. volume, entitled "Miscellaneous Tracts on various subjects," 1781. His experiments and observations on the singing of birds" (see *SONG OF BIRDS* in this Dictionary), and his "Essay on the Language of Birds" are amongst the most curious and ingenious of his papers. In private life he was a man of worth and integrity, unambitious, and devoted to study and literary conversation. He resigned his office of justice of Chester in 1785, and from that time to his death, March 14, 1800, lived in retirement in the Inner Temple. Gen. Biog.

BARRINGTON, in *Geography*, a township in Queen's county Nova Scotia, on the south side of the bay of Fundi, settled by Quakers from the island of Nantucket.

BARRINGTON, a township in Strafford county, New Hampshire, about 22 miles N. W. from Portsmouth, incorporated in 1722, containing 2470 inhabitants. Allum is found in this township, and the first ridge of the "Frost-hills," one of the 3 interior summits of Agasseticus, is continued through it. Its situation is very healthy, and favourable to longevity.

BARRINGTON, a township in Bristol county, Rhode island, on the south western side of the N. W. branch of Warren river, about 2½ miles N. W. of Warren, and about 7 S. E. from Fox point, in the town of Providence. It contains 683 inhabitants, including 12 slaves.

BARRINGTON, *Great*, is the second township in rank in Berkshire county in the Massachusetts. It contains 1373 inhabitants, and lies 140 miles W. from Bolton.

BARRINGTON, *Cape*, is the south-east point of lord Egmont's island, or New Guernsey, the largest of the Queen Charlotte's islands. It is separated by a narrow channel from cape Proby, on lord Howe's Island or New Jersey.

BARRINGTONIA, in *Botany*, a beautiful tropical tree named by Forster from the Hon. Daines Barrington. Lin. g. Schreb. 1150. Forst. gen. 38. L. supp. 50. Thunb. nov. gen. 47. Gerts. t. 101. *Mammia* spec. Edit. prior. *Commerfonta*. Soumerat Nov. Guin. 8. *Butonica* Rumph. Clafs. *Monadelphia Polyanthia. Polyandria Monogynia*, Forst. and Thunb. Nat. Order. *Hesperidaceae*.—*Alysi*, Juss.

Gen. Char. *Cal.* Perianth two leaved, superior; leaflets roundish, concave, coriaceous, permanent. *Cor.* Petals four, equal, ovate, spreading, coriaceous, larger than the calyx; nectary conic, tubular, coating the base of the style, toothed at the tip; teeth several, unequal. *Stam.* Filaments very many, monadelphous, (or conjoined from the very base into a cylinder seated on the receptacle), capillary, longer than the corolla; anthers small, roundish. *Pist.* Germ inferior, turbinate; style filiform, length of the filament; stigma simple. *Per.* Drupe large, ovate, conic-quadrangular, crowned by the calyx. *Seed.* nut long, ovate, outwardly wrinkled-fibrose, four-celled; kernels ovate, wrinkled.

Ess. Gen. Char. *Cal.* simple, two-leaved, superior, permanent; fruit a dry four-cornered drupe, inclosing a nut one to four-celled.

Species,

Species, *Barringtonia speciosa*, laurel-leaved B. Lin. Svlt. Supp. Cook, Voy. 1. 157. 24. *fg.* Forst. J. F. Miller. ic. 7. A lofty tree and the handsomest in the whole equinoctial flora, abounding with thick, shady bunches of leaves, every where intermixed with beautiful purple and white flowers; trunk lofty, thick, straight, covered with a dark grey, smooth bark, scored with little chinks; branches expanding widely, variously divided, somewhat bending downwards, and beset with many leaves at the ends; leaves crowded, the upper in a kind of whorl, sessile, wedge-shaped, obtuse, quite entire, expanding from a foot to fifteen inches in length, thick, coriaceous, very smooth, dark green, shining with yellow veins; flowers on a solitary erect thyrse, a foot in length; peduncle smooth, a foot long; pedicels five, to twenty, one-flowered, three or four inches long; bractes roundish, solitary at the base of the pedicels; flowers large, white, transparent; filaments and style diaphanous, purple at the top; anthers gold-coloured; drupe reddish brown. The flowers open during the night, and fall at sun-rise. The seed is said to incubate fish in the same manner as cocculus indicus, &c. It grows within the tropics, especially on the shores of the ocean and at the mouths of rivers, in the East Indies from the southern coasts of China through the Molucca isles to Otaheite and the other Society isles. It is cultivated in the governor's garden at St. Helena. Introduced here in 1786, by Mr. A. Hove.

BARRISTER, in *Law*, a person qualified and empowered to plead, and defend the causes of clients in the courts of justice. The word is formed from *bar*, *barra*, a name given the place where they stand to plead.

Barristers, in the English law, amount to the same with *licentiates*, and *advocates*, in other countries and courts, where the civil, &c. laws obtain.

Anciently they were denominated among us, *apprentices of the law*, *apprentici juris nobilitores*; now usually *counsellors at law*: and they seem to have been first appointed by an ordinance of king Edward I. in parliament, in the twentieth year of his reign.

Before they were called to the bar they were formerly obliged to study eight years, now reduced to five; the exercises required (if they were not called *ex gratia*) were twelve grand moots performed in the inns of chancery, in the time of the grand readings, and twenty four petty moots, in term time before the readers of the respective inns, and a barrister newly called was to attend the six (or four) next long vacations the exercise of the house, viz. in Lent and summer, and was thereupon for those three (or two) years styled a *vacation barrister*. They are also called *Utter barristers*, i. e. pleaders *ouster* or without the bar; to distinguish them from benchers, or those that have been readers, who are sometimes admitted to plead within the bar; as the king's, queen's, or prince's, counsel are; hence called *inner barristers*, 5 El. cap. 1.

Barristers, according to Fortescue, might be called to the state and degree of *serjeants*, when they were of sixteen years standing. See **COUNSEL** and **SERJEANT**.

Barristers who constantly attend the king's bench, &c. are to have the privilege of being sued in transitory actions in the county of Middlesex. But the court will not change the venue, because some of the defendants are barristers. Pleas before they are filed, must be signed by a barrister or serjeant.

To become a barrister in Ireland it is necessary in the first place that a memorial be presented by the person desirous of becoming so, to the Benchers of the Honourable Society of the King's Inns, Dublin, stating his parentage and previous education, and requesting admission into the society as a stu-

dent. This memorial certified by a practising barrister of ten years standing who is not a benchler, must be lodged in the office of the treasurer of the society before the effoin day of term; and on its being granted, a certain fine must be paid. After this admission the student must keep eight terms commons in Ireland, and the same number in England. Formerly a student was required to attend fewer terms if he had taken a degree in any university, and this was a strong inducement to those who intended their sons for the bar to give them a college education. It has been regretted that this encouragement was discontinued; but the advantages of such an education are so evident, that it is to be supposed few will neglect it; especially as they can attend terms at the society of the King's Inns, at the same time that they are members of the university.

BARRISTER *Applicant*, the name given to an inferior judge established in every county of Ireland, except that of Dublin, whose business it is to sit twice every year to try civil bills, for the more speedy administration of justice.

BARRITUS, in *Antiquity*, a military shout raised by the Roman soldiers at the first charge on the enemy. This custom, however, was not peculiar to the Romans; but prevailed among the Trojans according to Homer, among the Germans, the Gauls, the Macedonians, and the Persians. See **CLASSICUM**.

BARROCHES, in *Geography*, are two great ranges of rocks close by the west end of Alderney, Avigny or Ornay, towards the Caskets.

BARROS, JOHN DOS, in *Biography*, an eminent Portuguese historian, was born at Viseo, in 1496, and educated at the court of king Emanuel, with the royal children. In 1522 he was appointed to the government of St. George del Mina, on the coast of Guinea; and upon his return to Portugal, after an absence of three years, he was made treasurer of the Indies. When king John conferred upon him the lordship of Paraiba in Brazil, on condition of his expelling the native Indians, and peopling it with Portuguese, he set out with an expedition for this purpose; but his fleet being almost wholly destroyed, the project failed. Upon this he determined to write the history of the Indies, under the title of "Decades d'Asia;" and the first decad was published in 1552, the second in 1553, and the third in 1563. For the completion of this work he retired to Pompal, where he died in 1570, leaving several children. His fourth decad, compiled from his MSS. by order of Philip III. did not appear till 1615. The work has been continued by others as far as the thirteenth decad; and the last edition of it was printed at Lisbon in 1736, in 3 vols. folio. The history of dos Barros, applauded by some and censured by others, is deemed, notwithstanding the author's disposition to exaggerate, a work of authority. It was translated into Spanish by Alphonso Ulloa. Barros was the author of several other writings, moral, grammatical, &c. composed principally for the use of his pupil prince John, son of king John III. In some editions of his "Decads," there is an apology for his life and writings, written by himself. Moreri. Nouv. Dict. Hist.

BARROW, ISAAC, a very eminent divine and mathematician, was the son of Mr. Thomas Barrow, a citizen and linen draper of London, and born in this city in the year 1630. Although at the Charter-house, where his education commenced, he gained no reputation, and was remarkable only for fighting and idleness, his subsequent application and literary progress in a school at Felstead in Essex, whither he was removed, were such as to retrieve his character, and to induce his master to recommend him to the office of private tutor to a young noble-

nobleman under his care. In 1643 he was admitted a pensioner of Peter-house in Cambridge, under his uncle Mr. Isaac Barrow, afterwards bishop of St. Asaph, and then fellow of that college; and in 1645 he was entered a pensioner of Trinity college, as his uncle had been ejected together with others who had written against the covenant. The ejection of his uncle, and the losses sustained by his father on account of his attachment to the royal cause, involved our young student in difficulties; and he was indebted to the liberality of Dr. Hammond for his chief support. Such were the sweetness of his disposition and his respectful conduct towards his superiors, that he preserved their esteem and good-will, though he steadily adhered to the cause for which his family had suffered and refused to take the covenant. His proficiency in all branches of literature, and particularly in natural philosophy, was so considerable, and his merit so generally acknowledged, that he was elected, notwithstanding the obnoxiousness of the party to which he belonged, fellow of his college in the year 1649; and now perceiving that the circumstances of the times were unfavourable to persons of his opinions in matters of church and state, he determined to devote himself to the medical profession. With this view he directed his attention to anatomy, botany, and chemistry, and made some progress in these preparatory studies; however, upon further consideration, aided by his uncle's advice, he resumed the study of divinity in connection with that of mathematics and astronomy. With these severer studies he also blended the amusements of poetry, to which he had a strong propensity. In 1652 he commenced master of arts, and was incorporated in that degree at Oxford. Disappointed with regard to the Greek professorship at Cambridge (to which he was recommended) on account of a suspicion of his Arminian principles, and perhaps influenced by the aspect of public affairs, he resolved to travel abroad; and in order to obtain a necessary supply for this purpose, he sold his books. Accordingly he set out in the year 1655; and in this year his first work, which was an edition of "Euclid's Elements," was published during his absence. He visited France and Italy; and in 1656 he set sail from Leghorn to Smyrna; and in the course of his voyage he had an opportunity of manifesting his natural intrepidity by standing to his gun, and defending the ship on which he had embarked, against the attack of an Algerine corsair, and of beating off the enemy. Of his intrepidity, as well as bodily strength, another instance occurred on a very different occasion. As he was once leaving the house of a friend early in the morning before a fierce mastiff was chained up, the dog flew at him with violence; but he had the resolution to seize the dog by the throat, and after much struggling to overpower him, and to hold him fast on the ground till some of the domestics rose and parted them. From Smyrna he proceeded to Constantinople, where he read over with peculiar satisfaction the works of St. Chrysostom, the bishop of that see; and having remained a year in Turkey, he returned to Venice, and in 1659 he passed through Germany and Holland into England. Soon after his return he was ordained by bishop Brownrig; and when the king was restored, his friends expected that his attachment to the royal cause would have been rewarded by some considerable preferment: but their expectations were disappointed. On this occasion Barrow wittily remarked in one of his poems,

"Te magis optavit reditum, Carole, nemo,
Et nemo sensit te reddisse minus."

"Thy restoration, Royal Charles, I see,
By none more wish'd, by none less felt, than me."

VOL. III.

However, he wrote an ode on his majesty's restoration, in which he introduces Britannia congratulating the king upon his return. In this same year, 1660, he was chosen Greek professor at Cambridge; and in consequence of this appointment, he read lectures on the Rhetoric of Aristotle. In 1662 he was recommended by Dr. Wilkins, and elected to the professorship of geometry in Gresham college; and he also discharged the duty of the astronomical professor, who was absent. About this time he declined a valuable preferment which was offered him, from scruples of conscience; because it was annexed to the condition of educating the patron's son, which Barrow considered as a kind of fir. onical contract. In 1663 he was included in the first choice of members made by the Royal Society after receiving their charter; and in the same year he was appointed Lucasian professor of mathematics at Cambridge, on which occasion he delivered an excellent oration on the excellence and use of mathematical science. At this time he resigned both his Greek and Gresham professorships. Although the station to which he had attained was peculiarly adapted to his distinguished talents and acquirements as a mathematician, he determined in 1669 to exchange his mathematical studies for those of divinity; and accordingly, as soon as he had published his "Lectiones Opticæ," he resigned his professor's chair to the illustrious Newton. In 1670 he was created doctor in divinity by mandate; and in 1672 he was nominated to the mastership of Trinity college by the king, who observed "that he had bestowed it on the best scholar in England." To the patent of his appointment was annexed a clause which allowed him to marry; but as this privilege was inconsistent with the statutes of the college, he insisted on the clause being erased. On this occasion he resigned the preferments of a small sinecure in Wales, and of a prebend in the cathedral of Salisbury, which he had previously enjoyed and the profits of which he had distributed to charitable uses. In 1675 he was chosen vice-chancellor of the university; but his services in this high and honourable station were speedily terminated by his death, occasioned by a fever, in London, May 1677, in the 47th year of his age. His remains were interred in Westminster Abbey; and a monument, with an appropriate epitaph, was erected for him at the expence of his friends. Dr. Barrow had nothing in his person or external appearance, that was likely to command any degree of attention and respect. He was of a low stature, and of a meagre, pale aspect; and he was singularly negligent with regard to his dress. Pope, his biographer, mentions a circumstance to this purpose, which shews the effect of his inattention to outward appearance. Being engaged to preach for Dr. Wilkins at St. Lawrence Jury in London, his slovenly and awkward gait and meagre aspect prepossessed the audience so much against him, that, when he mounted the pulpit, the congregation withdrew and he was left almost alone in the church. Mr. Richard Baxter, the nonconformist divine, however, was one of those few that remained; and his testimony was highly honourable to the preacher, for he declared that he had never heard a better sermon, and that he could with pleasure have listened all day to such preaching; upon which those persons who complained to Dr. Wilkins of his substitute were ashamed of their conduct in deserting the church, and reduced to the necessity of acknowledging that their prejudice was solely the result of his uncouth appearance. His sermons were distinguished not only by their excellence, but by their length. He took great pains in composing them, and in transcribing them three or four times, as he found it extremely difficult to please himself. M. le Clerc (Biblioth. Univ. t. iii. p. 325)

says of them, that they were treatises or exact dissertations rather than harangues to please the multitude; and Dr. Tillotson, who published them, observes in his preface, that "their own excellence and eloquence will praise them best;" and king Charles II. used facetiously to call him "an unfair preacher," because he exhausted every subject, and left nothing for any person that came after him to say. The delivery of his Spital sermon concerning charity, before the lord mayor and aldermen, took up $3\frac{1}{2}$ hours; and being asked upon his leaving the pulpit, whether he was not tired, he replied "yes indeed, I began to be weary with standing so long." In his compositions he seems, as it were, to labour for words to express the amplitude and energy of his conceptions; and, on this account, his style is involved and interrupted by parentheses, though he sometimes introduces passages of sublime and simple eloquence. Dr. Barrow, as we may naturally imagine from the course of his studies and the character as well as the number of his writings, was unremitting in his application. He slept little, and generally rose in the winter months before day. He is said to have been intemperate in the use of fruit, alleging that if it kills hundreds in autumn, it preserves thousands; and he was much addicted to the use of tobacco, calling it his "panpharmakon," or universal medicine, and imagining that it helped to compose and regulate his thoughts. In his general disposition and conduct he was singularly amiable and pleasing. Such were his modesty and diffidence, that when he understood that his optical and geometrical lectures were to be printed in the Philosophical Transactions, he requested that they might be introduced with merely a simple and short account of them, without anything in commendation or discommendation of them; and on the occasion above referred to, when his congregation deserted him, he accounted for it to a friend by saying, "I thought they did not like me, or my sermon; and I have no reason to be angry with them for that." In conversation he was unreserved and communicative, often facetious and cheerful, and always anxious to adapt his discourse to different capacities. He was charitable in a mean estate, disinterested in a flourishing one, serene and content in all fortunes, of the strictest integrity, above all artifice and disguise, friendly and courteous. With these private virtues he combined the character of the greatest scholar of his times; and as Dr. Pemberton observes in his preface to the "View of sir I. Newton's Philosophy," "he may be esteemed as having shewn a compass of invention equal if not superior to any of the moderns, sir Isaac Newton only excepted." The chief property which he had accumulated consisted of books, which were well chosen, and sold after his death for more money than they cost. His own MSS in theology, were committed to the care of Dr. John Tillotson and Mr. Abraham Hill, with permission to publish such of them as they thought proper. They first appeared in 1685, in 3 vols. folio; there have been several editions since, and the last was in 1741. They consist of sermons, of expositions of the creed, the Lord's prayer, and the decalogue; of the doctrine of the sacraments, and of treatises on the pope's supremacy and the unity of the church. A fourth volume in Latin, intitled "Opuscula," was published in 1687; and consists of Determinationes, Conciones ad Clerum, Speeches, Latin poems, &c.

Dr. Barrow was no less distinguished as a mathematician than as a divine. The principal of his mathematical works are the following: viz. "Euclidis Elementa," Camb. 1655. 8vo., and translated into English and published at London in 1660. 8vo. In this edition of all the books and propositions of Euclid, the demonstrations are distinguished by their

conciseness. "Euclidis Data," Camb. 1657. 8vo., subjoined to the Elements in later editions. "Lectiones Opticæ XVIII.; Cantabrigiæ in scholis publicis habitæ, &c." Lond. 1669. 4to: this work was revised and enlarged by Newton, and has been highly commended by the best judges. "Lectiones Geometricæ XIII. in quibus præsertim generalia linearum curvarum symptomata declarantur;" Lond. 1670. 4to.: published in 1672 and 1674 with the "Optics." "Archimedis Opera; Apollonii Conicorum Libri IV.; Theodosii Sphærica, methodo nova illustrata, et succinctè demonstrata;" Lond. 1675. 4to. After Dr. Barrow's decease, were published his "Lectio in qua theorematum Archimedis de Sphæra et Cylindro, per methodum indivisibilium investigata, et breviter demonstrata, exhibentur;" Lond. 1678, 12mo.; and "Mathematicæ Lectiones, habitæ in scholis publicis Academiæ Cantabrigiendensis," Lond. 1683, 8vo. Besides these, Dr. Barrow left several curious papers, written with his own hand, and communicated by William Jones, esq. to Dr. Ward. Hill's Life prefixed to Barrow's Works. Ward's Lives of the Professors of Gresham college. p. 157, &c. Biog. Brit.

BARROW, in *Geography*, a noble river of Ireland, supposed to be the *Birgus* or *Brigus* of Ptolemy. It rises in the mountain of Sliabh-bloom in the King's county, and running for a short space north-east, makes a kind of elbow; and continuing afterwards a south-east course, it divides the King's and Queen's counties from that of Kildare. At Athy, in the latter county, a branch of the grand canal from Dublin to the Shannon has formed a junction with it; which contributes much to the advantage of the adjoining country. It proceeds next through the heart of the county of Carlow, and then separates those of Kilkenny and Wexford. A little before it reaches the town of Kofs, it receives the Nore; and then varying its course somewhat to the west, mingles its waters with those of the Suire, forming with it the haven of Waterford. The navigation of this river has been deemed of such great importance that 11000 pounds have been granted by parliament to remove some obstructions in it; and a corporation established for the purpose has been enabled to raise 20000 l. more to render it completely navigable. It is now (1802) expected that boats will soon regularly ply from Waterford to Athy, and thence by the grand canal to Dublin. The circumstance of the three rivers Barrow, Nore, and Suire, all rising in the same mountain, proceeding from it by different courses, and uniting their streams before they fall into the sea, has been mentioned by many writers. Amongst others, Spenser has noticed it in his epilogue of the marriage of the Thames and Medway (Fairy Queen, book iv. cant. 11.); in which he represents them as three brothers, sons of the giant Blomius and the nymph Rheusa. He speaks of the Barrow as abounding in salmon:

"The third, the goodly Barrow which doth hoord

Great heapes of salmon in his deepe bosome."

Campbell's Political Survey, &c. &c.

BARROW *Little*, a river of Ireland, which runs into the Barrow about 4 miles east of Portarlington.

BARROW *Harbour* is an extensive bay in that of Bonavista in the island of Newfoundland, divided by Keel's head on the E. from the port of Bonavista, and from Bloody bay on the W. by a large peninsula joined to the island by a narrow isthmus, which forms Newman's sound; which, as well as Clode sound, are within Barrow harbour.

BARROW *Point*, a cape on the south coast of Ireland, in the county of Cork, 5 miles east of Kinfale.

BARROWS, or *Tumuli*, in *Topography*, a name usually given to those hillocks or mounds of earth which were anciently

ciently raised over the bodies of deceased heroes and persons of distinguished character. This mode of interment may be traced to the remotest antiquity, and instances of it occur in all quarters of the world. A learned antiquarian, well known for his industrious and indefatigable research (see Gough's Sepulchral Monuments of Great Britain), considers barrows as the most ancient sepulchral monuments in the world. Homer is one of the earliest authors who mentions the construction of barrows, in describing the funeral rites attending the interment of Patroclus and Achilles. The body of Patroclus was first laid on the top of a great pile of wood about one hundred feet square, and covered with the fat of animals offered in sacrifice: the carcases of the beasts, and the bodies of the Trojan captives cruelly slain in cold blood on the occasion, were then thrown on the pile round its edges, and the whole reduced to ashes. The remains of the fire were next day extinguished by pouring wine on the embers; and as many fragments of the bones of the deceased as could be collected, were wrapped up in fat, and put into a rich urn, having a linen veil slung over it. The whole army then threw earth upon the spot where the pile had been consumed, so as to cover the bones of the Trojans, of the beasts, and all the ashes that remained, and thus reared a high rude hill, under which, nearly in the centre, the urn was placed. After this ceremony, solemn games were performed, and chariot races were exhibited round the barrow, in honour of the deceased. To this purpose, the elegant translator of Homer, in his account of the funeral of Patroclus, expresses part of the funeral ceremony:

“High in the midst they heap the swelling bed
Of rising earth, memorial of the dead.”

Iliad, xxiii. 319.

In Plutarch's Life of Alexander, we find that when that great conqueror arrived at the ruins of Troy, he anointed with much ceremony the stone placed on the barrow of Achilles, poured out libations, and, as the custom was, ran naked round the sepulchre, and crowned the stone with garlands.

Herodotus, the father of history, mentions the barrow of Alyattes, the second of that name, king of Lydia, and father of Cræsus, raised 2365 years ago, and seen by Dr. Chandler in A. D. 1764, five miles from Sardis, the ancient Sardis. This tumulus or barrow, formed by the joint exertions of the merchants, the labourers, and the prostitutes, was about a mile in circumference, 1300 feet broad, and terminated by a piece of water called the Gygean lake, still remaining. Dr. Chandler, in his “Travels through Asia Minor,” vol. i. p. 42. describes this and other barrows in their present state; and Herodotus states, that the lower part of it was a mass of large stones, but that the rest of the sepulchre was a tumulus of earth.

It was customary among the Greeks to place on barrows, either the image of some animal, or stone, terminal or round pillars with inscriptions. Pausanias describes the famous barrow of the Athenians in the plain of Marathon, on which were pillars of this kind: and on that of Alyattes were five stones, on which were engraved letters, denoting how much each class of the persons concerned had performed towards it, and it appeared that the greater portion was done by the young women. An ancient monument in Italy, near the Appian way, called without reason the sepulchre of the Curii, has the same number of termini with that of Alyattes, the basement, which is square, supporting five round pyramids. We are informed in the scriptures, that when the king of Ai was slain by Joshua, his carcase was placed at the entrance of the city, and upon it was raised a great heap of

stones. Several other passages of the sacred writings lead us to conclude, that though the Jews were prohibited from adopting the superstitious customs of the gentile nations, they did not think themselves restrained from constructing these memorials to their deceased relatives. Diodorus Siculus, speaking of the Bulliazæ, says, that after piecing together the limbs of a dead body with boards, they cast it into a hollow receptacle, and placed over it a large heap of stones. Virgil alludes to this mode of interment as used in Italy in the times to which the Æneid refers. Xenophon relates that it obtained among the Persians; the Roman historians record it as taking place among their countrymen; and it prevailed no less among the ancient Germans, Britons, and other nations.

According to Herodotus, the Gerrii, a people of Scythia, raised barrows; and the custom of erecting them in various parts of the world continued through a long series of ages. Gough says, that they continued in use till the 12th century.

The ancient barrows are of various sizes, some of them being small, and perhaps designed for children, or the younger branches of the royal family, or for persons of meaner rank; others distinguished by their height and bulk, and visible like hills at a great distance, which might probably have been the sepulchre of some renowned monarch or warrior, or general burying-places.

Stahlenberg, in his description of the northern and western parts of Europe and Asia, informs us, that great numbers of tumuli, called by the Russians “bogni,” are found in Siberia, and in the deserts which border on that country southward; and that in these tombs are found many plates, ornaments, and trinkets of gold. Some of them are raised by earth as high as houses, and appear in the distant plains like a ridge of hills; whilst others are set round with rough-hewn stones. *Archæologia*, vol. ii. p. 236.

The custom of interring with the dead their arms, their jewels, and sometimes their horses and servants, is traced by M. Legrand D'Aussy (*Mem. de l'Institut National des Sciences*, &c. Paris, vol. ii.) to the mythology of the northern Asiatic nations, which taught them to believe that they should make an appearance in another world, corresponding to the ornaments and attendants deposited in their tombs; and the remains of this superstition have descended through many ages. According to this writer, a great part of the riches acquired by the northern nations in their irruptions, has been interred in the tombs of the conquerors. Treasures have been frequently found in the barrows so common in Tartary; and, in attempting to ransack these monuments, the Siberians have had so many conflicts with the Tartars, that the Russian government has been obliged to put a stop to their researches.

Denmark, Sweden, Lower Saxony, and many other countries on the continent, abound with sepulchral monuments of this kind. Mr. Coxe, in his “Travels in Poland,” (vol. i. p. 130.) mentions two large barrows in the vicinity of Cracow; one by tradition called the burial-place of Cracus, duke of Poland, who is supposed to have built the town in the year 700; and the other called the sepulchre of his daughter Vanda, who is reported to have drowned herself in the Vistula to avoid a marriage with a person whom she detested. As popular tradition records these as favourite characters in their country, it has honoured them with interment under the most conspicuous of those monuments called barrows.

The barrows of England are very numerous scattered over the plains of Wiltshire, the downs of Dorsetshire, Kent, and Surry. Monuments of the same appropriation

are also abundant in the northern counties of England, North Wales, Scotland, and Ireland; but most of these consist of vast piles of stones, and are designated by the name of "cairn," or "cairn." (See *CARN*.) The most considerable barrow in England is that of Silbury Hill in Wiltshire. (See *AVEBURY*.) A barrow in Derbyshire, situate on the summit of a hill called "Fin-cop," has been carefully investigated by Mr. Hayman Rooke. (See *Archæologia*, vol. xiii.) It disclosed two or three skeletons, one of which had an oblong piece of dressed black Derbyshire marble fastened by a strong cement to the skull: some urns also appeared, with ashes and burnt bones, together with arrow-heads of flint, and a spear-head shaped out of a piece of lime-stone, and made very sharp at the point. Mr. Rooke conjectures, that this elevated spot, secured by a double fence, may have been the site of a British town or fortress, and that the barrow was the sepulchre of the chieftain and his relatives; the weapons of flint and of lime-stone undoubtedly suggest a very remote period, and, when found as these were, appear to indicate the relics of a primitive and barbarous people. Dr. Plott takes notice of two sorts of barrows in Oxfordshire, one placed on the military ways, the other in the fields, meadows, woods, &c.: the former he supposed were of Roman erection, and the latter were more probably erected by the Britons or Danes. Some of these barrows appear rude, and constructed only of earth; others are more regular, and trenched round, some of them with two or three circumvallations, and surmounted with monumental stones. (Plott's *Nat. Hist. Oxfordshire*, ch. x. § 48.) We have an examination of the barrows in Cornwall by Dr. Williams, in the "Philosophical Transactions," N^o 458; from whose observations we find, that these barrows are composed of foreign or adventitious earth; that is, such as does not occur on the spot, but must have been fetched from some distance. In one of them was found an urn made of burnt or calcined earth, very hard, and very black within; it had four small handles, and in it were found seven quarts of burnt bones and ashes. As it was the ancient practice to burn the dead, it appears from these barrows, how the people that used this mode of burial expressed their respect for the dead; it was by erecting over them these tumuli or barrows, composed of earth or stone brought from distant places; and the barrow was generally proportioned to the rank and power of the deceased person. Each soldier, or friend, might bring some of the earth or stones from distant places where they lived, and thus compose the tumulus. Many passages might be quoted from ancient authors to this purpose. The contents of these barrows, as well as their size and form, have been very various: in some have been found stone chests containing entire bones; and in others, bones neither lodged in chests nor deposited in urns: arms of various sorts, amber beads, &c. have not been uncommon.

The links or sands of Skail in Sandwick, one of the Orkney islands, abounds in round barrows, some formed of earth alone, and others of stone covered with earth. In the former was found a coffin made of six flat stones, and as it was too short to receive a body at full length, the skeletons had their knees pressed to the breast, and the legs doubled along the thighs. A bag made of rusks has been found at the feet of some of these skeletons, which contained the bones, probably, of another person of the same family. In one of these were discovered multitudes of small beetles; and as similar insects have been found in the bag which inclosed the sacred Ibis, it may be supposed that the Egyptians, and the nation to which these tumuli belonged, might

have had the same superstition respecting them. Some of the corpses interred in this island appear to have been burned; as the ashes deposited in an urn which was covered with a flat stone, have been found in the cell of one of the barrows. This coffin, or cell, was placed on the ground, then covered with a heap of stones, and cased with earth or fods. This barrow and its contents evince them to be of a different age from the former. These tumuli appeared to be a kind of family vaults, two tiers of coffins having been found in them; and it is not improbable, that on the death of any one of the family, the tumulus was opened, and the body interred near its kindred bones.

Barrows are very numerous in Ireland. Ledwich supposes them to have been of Scythian origin, and to have been introduced in Britain after the Romans had left it. It was a law of Odin the great Gothic legislator, that large barrows should be raised to perpetuate the memory of celebrated chiefs: these were composed of stone and earth, and were formed with great labour and some art. At New Grange in the county of Meath is a mount of this kind, the altitude of which from the horizontal floor of the cave is about 70 feet, the circumference at the top is 300 feet, and the base covers two acres of land. It is founded on an astonishing collection of stones, and covered with gravel and earth. In the "brände-tiid," or fiery age, which was the first among the Northerns, the body was ordered by Odin to be burned with all its ornaments, and the ashes to be collected in an urn and laid in a grave; but in the "hoelst-tiid," or age of hillocks, being the second, the body, untouched by fire, was deposited in a cave or sepulchre under a barrow; and this mode was practised till the third epoch, called "christendoms-tiid," or the age of Christianity. Governor Pownall, who has given an account of New Grange, in the second volume of the "Archæologia," observes, that the mode of burial, and the species of sepulchral monument at New Grange, may be traced through Denmark, Sweden, Russia, Poland, and the steppes of Tartary; and he conjectures that this mount was a Danish work; which was also the opinion of sir Thomas Molyneux, M. D. in his "Essay on Danish Mounts," published with "Boate's Natural History of Ireland." About 1699, a Mr. Campbell, who resided in the village of New Grange, observing stones under the green sod, carried many of them away, and at length arrived at a broad flat stone that covered the mouth of the gallery. At the entrance, this gallery is 3 feet wide and 2 high; at 13 feet from the entrance, it is but 2 feet 2 inches wide: the length of the gallery, from its mouth to the beginning of the dome, is 62 feet; from thence to the upper part of the dome, 11 feet 6 inches; the whole length being 71½ feet. The dome or cave, with the long gallery, exhibits the exact figure of a cross, the length between the arms of which is 20 feet: the dome forms an octagon, 20 feet high, with an area of about 17 feet; it is composed of long flat stones, the upper projecting a little below the lower, and closed in and capped with a flat flag. There are two large oval rock basins in this cave, one in each arm of the cross; from which, and the cruciform shape of the structure, it is supposed to be the work of semi-christian Ostmen in the ninth century. The custom of burying the treasure acquired by piracy, in the barrows of great men, accounts for the Roman coins found at New Grange. For a more particular account, the reader is referred to Mr. Ledwich's *Antiquities of Ireland*, p. 307—328. General Vallancey, however, and other antiquarians, consider this cave at New Grange to have been "antrum Mithræ," or a cave for the worship of the sun, introduced

by the Peruvian colony, which they suppose to have come to Ireland from Spain, and to have established the customs of the eastern nations.

Tumuli or barrows are also found in great numbers in America; and the American Indians are said to practise a familiar mode of burial at this time, generally depositing with the bodies the implements of war and agriculture used by the deceased. Mr. Jefferson, in his "Notes on the State of Virginia," p. 156, has given a particular account of the American barrows. They are of different sizes, and formed of different material; some of earth, and some of loose stones. That they were repositories of the dead is generally allowed; but the particular occasion on which they were constructed has been a subject of discussion. Some have thought that they covered the bones of those who fell in battles fought on the spot of interment. Some ascribe them to the custom prevalent among the Indians, of collecting at certain periods all their dead, wheresoever deposited at the time of their death. Others again have supposed that they were general sepulchres for towns, conjectured to have been situate on or near those grounds: and this is an opinion that has been supported by the quality of the lands in which they are found, those constituted of earth being generally in the softest and most fertile meadow grounds, on the sides of rivers; and also by a tradition descending from the aboriginal Indians, which reports, that when they settled in a town, the first person who died was placed erect, and in this posture covered and supported by earth: that when another died, a narrow passage was dug to the first, the second reclined against him, and the cover of earth replaced, and so on. Mr. Jefferson examined one of these barrows, situate in his own neighbourhood, on the low grounds of the Rivanna, opposite to some hills on which had been an Indian town; and has particularly described its form, which was spheroidal; and also its contents, which were collections of human bones in a disjointed and scattered state. This barrow, he conjectured, might have contained a thousand skeletons. The circumstances which he has recited militate against the opinion that it covered the bones only of persons fallen in battle; and against the tradition, which would make it the common sepulchre of a town, in which the bodies were placed upright and touching each other; and indicate, that it has derived both origin and increase from the customary collection of bones, and the deposition of them together. But in what way soever this tumulus was formed, it seems to have been well known to the Indians; a party of whom, some years ago, proceeded through the woods directly to it, without any inquiry; and having remained near it for some time with expressions of sorrow, they returned to the high road, from which they had departed about six miles for the purpose of this visit, and then pursued their journey. There are many other similar barrows in other parts of the country. For further particulars relating to sepulchral monuments of this kind, we refer to Gough's Sepulchral Monuments of Britain; Douglas's Nenia Britannica; King's Monimenta Britannica; Archæologia, vol. ii. & xii.; and Britton's Beauties of Wiltshire, vol. ii.

BARROWS, in the *Salt Works*, are cases made with flat cleft wickers, in the shape almost of a sugar-loaf, with the bottom uppermost, wherein the salt is put as it comes, and fet to drain. Phil. Trans. N^o 53, p. 1865. Hought. Collect. N^o 211, p. 81.

BARROWBY, WILLIAM, in *Biography*, son of Dr. William Barrowby, a physician of considerable repute and eminence in London. At a proper age he was admitted of Emanuel college in Cambridge, and in 1733 took his degree

of Bachelor in Medicine. Soon after, he was made fellow of the Royal College of Physicians in London, and one of the physicians to Bartholomew's hospital. He died suddenly, after eating a hearty meal, December 30, 1752, being only forty-two years of age, and then in great practice. There is a fine print of him, engraven in mezzotinto by Müller, after a painting by Flaxman. His father, who survived him, died October 17th, 1756, being then senior member of the college of physicians. One author published, in 1737, a translation into English of Aduca's treatise "De Morbo Gallico," London, 2 v. 8vo. Eloy. Dict. Hist.

BARROWISTS, in *Topographical History*. See BROWNISTS.

BARRULET, or BARRULET, in *Heraldry*, signifies a diminution of the bar, consisting of its fourth part.

BARRULY denotes the field of the shield of arms, when it is divided bar-wise into many equal parts.

BARRY, EDWARD, in *Biography*, a native of Dublin, received his medical education at Leyden, and the celebrated Boerhaave, and was created doctor of physic there in 1719. After practising some years at York, he went to Dublin, and was made professor of medicine in the university of that city, first physician to the army there, and fellow of the Royal Society in London. In 1727, he published "a treatise on a consumption of the lungs, with a previous account of nutrition, and of the structure and use of the lungs," 8vo. London, in which he maintains the doctrine of his preceptor. To the third edition of this work, enlarged and improved, published 1759, he gave the title of "A treatise on the three Digestions and Discharges of the Human Body, and the Diseases of their principal Organs." Haller. Bib. Anat. Eloy. Dict. Hist.

BARRY, GERALD, commonly called *Giraldus Cambrensis*, i. e. Girald of Wales, in *Biography*, a writer of the twelfth century, was born near Pembroke in South Wales about the year 1146, and descended from a noble family allied to the princes of the country. After an early education at home, he was sent for further improvement to France, where he obtained great reputation for his proficiency in the rhetoric of the age in which he lived. Upon his return in 1172, he obtained several ecclesiastical preferments, of which the principal were the archdeaconry of Bœchin, and the canonry of Hereford. As he was active in church affairs, he acquired a reputation which induced the chapter of St. David's to elect him bishop of that see at the age of 30 years; but as he had reason for apprehending the jealousy of king Henry II., he declined this ecclesiastical dignity. However, he was mortified by being under a necessity of refusing what was the great object of his ambition; and in order to divert his chagrin, he visited France; and at Paris he pursued his study of civil and canon law, and of divinity, with such success, that he was offered the professorship of canon law in the university; but he thought proper to decline it. In 1180, he returned to his own country; and as great confusion prevailed at St. David's in consequence of the expulsion of the bishop, he was entrusted with the administration of that see for three or four years. In 1184, Henry II. appointed him his chaplain, and availed himself of his advice in the management of Welsh affairs. In the following year he was sent to Ireland with prince John as his privy-counsellor and secretary; and was there offered the united bishoprics of Ferm and Leighlin, which he declined accepting, because he disapproved of the measures pursued by John. During his stay in that country, he was principally employed in collecting materials for two works relating to Ireland

Ireland which he had projected. After his return to Wales, in 1187, he wrote and revised his "Topography of Ireland;" and at Oxford, he publicly recited the three parts of the work on three successive days, feasting on the first day all the poor of the city, on the second the principal doctors and scholars, and on the third scholars of inferior rank, soldiers, and burgesses. In the following year he accompanied Baldwin of Canterbury in a journey through the mountainous parts of Wales, for the purpose of inculcating on the people the necessity of a crusade; and he was thus furnished with materials for his "Itinerary in Wales," which he afterwards published. At this time Girald took the cross; but being otherwise employed at home, he obtained a dispensation from the pope's legate for not pursuing his voyage to the Holy Land in the retinue of king Richard I. Upon some disgust, he retired from court in 1192, and took up his abode for six or seven years at Lincoln, where he pursued his theological studies and composed various writings. In 1198, he was solicited by the chapter of St. David's, and the chief men of the country, to canvass for the vacant see; but in declining it, he made use of a saying which has become memorable; "Virum episcopalem peti, non petere, debere," i. e. a man fit for a bishoprick ought to be sued to, and not sue. However, he soon changed his mind; for being next year unanimously chosen by the chapter, he went over to Ireland to engage his relations in support of his claim. But during his absence, a mandate was issued from the archbishop and judiciary for the election of Geoffroy the prior of Llanthony. Girald appealed to the pope; and after much delay and three journeys to Rome, he only so far prevailed as to annul the election, and to obtain the appointment of a new choice. Geoffroy was at length the successful candidate; upon which Girald resigned his archdeaconry of Brechin to his nephew, and withdrawing from public concerns, devoted himself to his studies. In 1215, he was offered the bishopric of St. David, but the offer was connected with conditions which he did not approve. The time of his death has not been precisely ascertained; but it is known that he was alive after the year 1220.

Giraldus Cambrensis was a voluminous writer; and there were few of the literary topics of his age that did not employ his pen. According to the account given of him by Mr. Thomas Wharton (Hist. of Poetry, diss. ii.), he was an historian, an antiquary, a topographer, a divine, a philosopher, and a poet. Many of his works, he says, are written with some degree of elegance, and he abounds with quotations from the best Latin poets. But his style is in general puerile, affected, diffuse, and full of quibbles and conceits: nevertheless, many of these defects must be attributed to the times in which he lived. Whatever may be thought of the vanity which he manifests in speaking of himself, of his family, and of his performances, he was without doubt in a very great degree credulous, and so much addicted to fables, that his statement of facts is in many cases unworthy of confidence. With the events recited in his "History of the Conquest of Ireland," he has intermixed all the prophecies he could collect of Caledonius, Merlin, and various other impostors; and hence he was led to give to his history the title of "Vaticinal." This work, and also his "Topographia Hibernica," have been charged by the Irish writers with numerous mistakes and falsehoods. They were first printed by Camden, at Frankfort, in 1602. His "Itinerarium Cambrie" was printed with the annotations of David Powel. The purpose of his "Ecclesiæ speculum, sive de monastriis ordinibus, ex ecclesiasticis religionis variis distinctionibus, lib. iv." was to expose the vices of the monks, against whom he had conceived an inveterate hatred, so that he was ac-

cused to add to his litany, "From the malice of the monks, good Lord, deliver us." Biog. Brit.

BARRY Island, in *Geography*, the westernmost of two islands off Cardiff point, on the coast of Wales, in the county of Glamorgan.

BARRY'S P. lat., a projecting head land, on the west side of Little Island, up Cork harbour.

BARRY, in *Her. liby.*, is when the shield is divided into equal parts horizontally, consisting of two colours: or thus, Barry of six, argent and sable.

BARRY Bendy Counterchanged, is when the bars are crossed by lines bendwise. See *Plate of Partition lines*.

BARRY Indented, is when the lines which cross the field to form the bar are indented.

BARRY Wavy and **Barry Nebulé**, are formed in the same manner by the lines being wavy nebulé.

BARRY Lozengie Counterchanged, is when the bars are crossed by lines bendwise, dexter and sinister. See *Plate as above*.

BARRY Pily, is when the bars are charged with piles. See *Plate as above*.

BARRYERAS VERMELLIAS, in *Geography*, is a large bay, with very good anchoring on the coast of Brazil, between St. John's island and Sypomba island, 7 leagues north-east from it; situate in about 2° S. lat. and S. E. of the mouth of the great river Amazons.

BARS, a town of Hungary, and chief place of a county of the same name, eight miles west of Leventz.

BARS, or *Barco. Cape*, lies on the east side of the passage into the White sea, and to Archangel, from the N. W. and is the north point of the gulf of Mezene. N. lat. 66° 30'. E. long. 41° 45'.

BARSA, in *Ancient Geography*, an island near the coast of France, mentioned in the Itinerary of Antonine. See *Isle of Bas*.

BARSAIUM, a town of Asia, seated on the banks of the Euphrates, on the east of Samofata.

BARSELLACH POINT, in *Geography*, a cape of Scotland, on the coast of the county of Wigton, in Luce bay, 8 miles N. W. of Burrowhead.

BARSAI, a kingdom of Africa, bordering on the river Gambia, and inhabited by a tribe of negroes called **JALOFFS**. The government of this kingdom is a despotic monarchy; and the people are in such an abject state of submission, that they fall on their faces whenever any one of the royal family appears. In time of war, every soldier has his share of booty; and the king contents himself with a very moderate portion. The kingdom is divided into a number of provinces, over which the king appoints governors, called "bumeys," who pay him an annual homage and send a certain tribute or revenue to the exchequer. These bumeys, though powerful and absolute within their respective jurisdiction, are subject to the absolute dominion of the sovereign. The king maintains his despotic power so completely, that he admits of no other counsellor besides his prime minister, who is himself in reality his prime slave. This minister is also the general of the king's forces, and the interpreter of his will, from the very letter of which he must never deviate. The king and court profess the Mahometan religion, though they pay little regard to that part of it which forbids the use of wine; for the king cannot live without brandy, nor is he ever more devout than when he is drunk. When he stands in need of a fresh supply of brandy, or of any other necessary, he sends to the governor of James fort, begging that he will dispatch a boat with the merchandize for which he has occasion; and for the payment he plunders the neighbouring towns, and seizes

a certain number of his subjects, whom he sells for slaves, and exchanges for European commodities. The general dress of the people is a kind of callico surplice that hangs down below the knee, and is sometimes plaited about the waist; and they also wear a great number of gold trinkets in their hair, ears, noses, and round their necks, arms, and legs. The king of Barfalli, whom Moore saw in 1732, had a prodigious number of women; but when he went abroad, he was seldom attended by more than two, who seemed to be dressed out in the whole finery and jewels of the seraglio. The presumptive heirs of the crown paid the same servile homage to the sovereign with his lowest subjects: nevertheless it was usual for the king's children to dispute the right of succession with his brethren; and the longest sword generally gained the prize. *Mod. Un. Hist.* vol. 14, p. 164, &c. See JALOFFS.

BARSANIANI, in *Church History*, a sect who held all the errors of the Severians and Theodosians.

BARSANTI, FRANCISCO, in *Biography*, a native of Lucca, born about the year 1690, studied the civil law in the university of Padua; but, after a short residence there, he chose music for his profession. With this view he placed himself under the tuition of some of the ablest masters in Italy; and having attained a considerable knowledge both in the practice and theory of the art, he determined to settle in England, and came hither with Geminiani, who was also a Luchese, in the year 1714. He was a good performer on the hautbois when he first came over, and also on the flute: as a hautbois player, he found employment in the opera band; and derived considerable profit from teaching the flute. He published, with a dedication to the earl of Burlington, six solos for a flute with a thorough base, and afterwards six solos for a German flute and base. He also formed into sonatas for two violins and a base, the first six solos of Geminiani. He continued many years a performer at the opera house. At length having encouragement to remove to Scotland, he went thither; and it may be said of him with greater truth than of David Rizzio, that he meliorated the music of that country by collecting and making bases to a great number of the most popular Scots tunes.

About the year 1750, Barsanti returned to London; but being advanced in years, he was glad to be again employed in the opera band as a performer on the tenor violin; and in the summer season, in that of Vauxhall. At this time he published twelve concertos for violins, and soon after *Sci Antifone*, in which he endeavoured to imitate Palestrina and the old ecclesiastical composers. But the profits arising from these publications were so small, that the sale did not cover the expence of printing them. Barsanti was an excellent harmonist; but his productions were dry and fanciless. He acquired small sums by correcting the productions of young composers, and making bases to those of old pretenders to counterpoint. But towards the end of his life, he subsisted chiefly by the industry and economy of an excellent wife whom he had married in Scotland, and the studies and talents of a worthy and ingenious daughter, who, with the most promising voice and disposition for music, had been bound apprentice to a master who had undertaken to prepare her for a public singer, and with whom she had vanquished all the difficulties of the art in point of execution; but she totally lost her singing voice, on going to Oxford to perform at a choral meeting, by sickness in a stage coach; and never being able afterwards to sing, she was engaged by Colman as a comic actress at his theatre in the Haymarket; and having a great fund of natural humour, and a good figure, acquired great applause. The winter after she went to Ireland, and became a favourite actress in humorous parts, and at length was married to Mr. Da-

ly, the manager of the Dublin theatre; but died soon after to the great regret of all who knew her.

BARSHIRS, in *Geography*. See BASCHKIRS.

BARSCHLING, or BÖRSTLING, in *Ichthyology*, one of the synonymous names of the common perch, *perca fluviatilis*. Vide *Marfigl. Danub.* &c.

BARSE, an English name for the common perch, a well-known fresh-water fish. It is also the name now in use for the same fish in the Saxon language, and is one of the many Saxon words we have yet retained.

BARSERS, in *Geography*, a town of Norway, 50 miles N.E. of Romfald.

BARSIR, a town of Persia, in the province of Kerman, 60 miles N.E. of Sirgian.

BAROUND, lies on the coast of Sweden, in the Baltic, 15 leagues N. by W. from the north end of Oeland island, and nine leagues from the Westerwyk channel, among a labyrinth of rocks, impassable except by direction of pilots at Oeland.

BAKT, a port on the southern coast of Nova Scotia.

BART is also a township of Lancaster county, in the state of Pennsylvania.

BARTAPOUR, a town of India, in the country of Kemaon, on an island in the Ganges, 93 miles east of Bercilly, and 90 north of Lucknow.

BARTAS, WILLIAM DE SALLUSTE DU, in *Biography*, a French poet, was born, in 1544, at Montfort in Armagnac; and having entered into the service of Henry IV. he was employed by him in commissions to England, Denmark, and Scotland, in which last country James VI. would gladly have retained him. He was a Calvinist, and acquired in times of bad taste the reputation of a poet. His works were numerous, written in a style, sometimes mean and barbarous, and sometimes tumid and extravagant, and abounding with ludicrous and disgusting figures. His most famous work was "A Commentary on the Work of the Creation of the World," in 7 books, which was held in high estimation, and passed through 30 editions, was translated into various languages, and formed a part of almost every religious library. Bartas is highly commended by *Monf. de Thou* for his candour, modesty, and simplicity of manners. Towards the close of his life he retired to his small estate of Du Bartas in Armagnac, and devoted himself to study. He celebrated in verse the victory of his master Henry at Ivry in 1590, and died in the following year. His works were collected and published in folio, at Paris, in 1611. *Gen. Dict. Nouv. Dict. Hist.*

BARTAVELLE, in *Ornithology*, among the French naturalists, the same bird which Latham describes under the name of *perdic rufa*; which see.

BARTEN, in *Geography*, a town of Prussia, and capital of a small country called Bartenland, in the province of Natangen, 40 miles S. E. of Königsberg.

BARTENSTEIN, a town of Prussia, in the province of Natangen, seated on the river Aa, 28 miles south of Königsberg. This town was built in 1331, and at first called *Rejntbal*.

BARTENSTEIN is also a town and castle of Germany, in the circle of Franconia and principality of Hohenlohe.

BARTERING, in *Arithmetic* and *Commerce*, the act of trucking or exchanging one commodity for another of like value.

The word comes from the Spanish *baratar*: to derive or circumvent in bargaining; perhaps because those who deal this way usually endeavour to over-reach one another.

This is also called *bartry*, 13 Eliz. cap. 7.

In order to solve all questions that occur under this article, find the value of that commodity, the quantity of which

which is given, and then find how much of the other commodity will amount to that sum at the rate proposed.

Example I.—How many pounds of cotton at 10d. per lb. must be given in barter for 5 C. 3 qrs. 14 lb. of pepper at 3l. 15s. per C.?

First, find the value of the commodity, the quantity of which is given, thus:

	C	Q	lb.	l.	s.	
	5	3	14	at	3	10
3 l.	15					Or, by decimals,
10 "	2	10				5 C. 3 Q. 14 lb. = 5.785
2 q.	1	15				3 l. 10s. = 3.5
1 q.		17	6			And 1 : 3.5 :: 5.785 : 20.5625 =
4 lb.		8	9			20 l. 11 s. 3 d. the value of the
						pepper.
	£	20	11	3		

Secondly, find how much cotton at 10 d. per lb. may be purchased for 20 l. 11 s. 3 d. thus:

d.	lb.	l.	s.	d.
50	:	1	::	20
				11
				3
				:
				493.5
				:
				20
				:
				411
				:
				12
				:
				10
				4935
				:
				493.5

As the values or prices of the goods bartered are always equal, it is evident that the product of the quantities bartered into their respective rates must be equal. Hence we obtain the following rule by which many questions of this nature may be solved; viz.

Multiply the given quantity and rate of one commodity, and the product divided by the rate of the other commodity will give the quantity; or divided by the quantity, will give the rate.

Example II.—How many yards of linen at 4s. per yard may be had in barter for 120 yards of velvet at 15s. 6 d. per yard?

yds. shillings.

$$120 \times 31 = 3720, \text{ and } \frac{3720}{8} = 465 \text{ yards.}$$

See EXCHANGE.

BARTH, JOHN, in *Biography*, a fisherman at Dunkirk, was born in 1651, and rose by his courage and naval skill, first to the command of an armed galliot in 1675, and at length, in 1692, to the rank of commodore of a squadron in the navy of France. By his nautical conduct and intrepid bravery he performed many signal exploits, and rendered himself the terror of the narrow seas. In consequence of one of his gallant actions, he was ennobled by Louis XIV.; but he still retained the rough manners of a tar. "John Barth," said the king to him on one occasion, "I have made you a commodore." John replied, "You have done right." This naval officer, distinguished more by daring and prompt enterprises than by any comprehensive and complicated plan, died in 1702, and was buried in the great church of Dunkirk. *Nouv. Dict. Hist.*

BARTHE, NICHOLAS THOMAS, was the son of a merchant at Marseilles, and born in that city in 1733. He was educated under the fathers of the oratory; and obtaining a prize from the academy of his native place, he afterwards became a member of it. His father had destined him for

the bar; but his talents led him to the cultivation of polite literature and poetry. Removing to Paris, he devoted himself to the theatre; and in 1764, began to write for the stage. His pieces were "L'Amateur," "Fausset Infidelies," "La Mere jalouse," and "L'Homme personnel." The two last were well received, but the last did not possess sufficient energy and vivacity to please the public. Barthe then ceased to write for the stage, and engaged in a translation of Ovid's "Art of Love." He also published a collection of fugitive pieces in verse, in which species of composition he excelled. His epistles are also admired for their philosophical gaiety. Barthe blundered with impetuosity of temper a friendly heart. Attached to social pleasures, he passed his time chiefly at Paris; and after having undergone the operation for an incarcerated hernia, died in this city in 1785. *Nouv. Dict. Hist.*

BARTHE, *De Nihilis (La)*, in *Geography*, a town of France, and principal place of a district, in the department of the higher Pyrennees, 6 leagues south of Tarbes. N. lat. 43° 4'. E. long. 0° 17'.

BARTHELEMY, JOHN JAMES, in *Biography*, a French abbe, distinguished by his literary character, was born in Jan. 1716, at Cassis, a small port in Provence. At the age of twelve years he was sent to Marseilles, and pursued his studies in the college of the oratory under the instructions of father Renaud. As he intended to devote himself to the ecclesiastical profession, he removed to the Jesuit's college for the study of theology and philosophy; but dissatisfied with his masters, he formed a plan of private study, which comprehended the Greek, Hebrew, Chaldean, and Syrian languages, and in the prosecution of which he brought on a dangerous illness. Upon his recovery he entered into the seminary, where he received the clerical tonsure; and by the assistance of a young Maronite, he became a proficient in the Arabic language. From Marseilles he retired to his family at Aubagne, and in this domestic retreat pursued his studies with unabated application. Among his friends at Marseilles, whom he occasionally visited, was M. Cary, who possessed a choice cabinet of medals and an appropriate library, to which he had access; and he was thus led to indulge the predilection for this kind of study, which distinguished his researches and character in the progress of his life. In 1744 he visited Paris, and was introduced by M. de Boze, keeper of the royal medals and secretary of the academy of inscriptions, to the most eminent members of the three academies, and also recommended to be his assistant in the care of the cabinet of medals. In 1747, he succeeded M. Burette as associate to the academy of inscriptions, M. Le Beau declining a competition; and when he was nominated by the minister to the office of secretary to the academy, he waved the nomination in favour of M. Le Beau, as an acknowledgment of his liberality. In return, M. Le Beau, when he resigned this office, gave his interest to Barthelemy, who succeeded him. Thus did these distinguished rivals vie with each other in the exercise of a liberality which reflected equal honour on both. Barthelemy enriched the Memoirs of the academy by many communications relating to ancient monuments, and among others, by a valuable dissertation on the inscriptions found at Palmyra by the English travellers. On the death of M. de Boze, in 1753, Barthelemy succeeded him as principal keeper of the medals. In the following year he followed M. de Stainville, afterwards duke de Choiseul and prime minister, to Rome, and made a tour to Naples, where the subterraneous treasures of Herculaneum and Pompeia engaged his particular attention, and where he exerted himself with peculiar zeal in the preservation of the Greek manuscripts. As he was not allowed to make any transcript,

transcript, it was by some contrivance and with the help of a retentive memory that he was able to bring away a specimen of the most ancient mode of writing practised by the Greeks. On his return to Rome he gained great applause for a new and ingenious explanation of the famous mosaic at Palestrina, the ancient Præneste, which, according to him, related not to Sylla, but to the emperor Adrian. In 1757, Barthelemy returned with his patron M. de Stainville to Paris, who, on his accession to the office of prime minister in 1758, anticipated and more than gratified his wishes, which were moderate, by various pensions, and at length by the place of secretary-general of the Swiss. When his patron Choiseul was banished, in 1771, to his seat of Chanteloup, in order to make way for D'Aiguillon, Barthelemy accompanied him in his exile, and as he determined to resign his secretaryship, an accommodation took place, by which he retained a pension of 10,000 livres on the post. His income was now about 35,000 livres per annum, which he reduced, by several grants to indigent men of letters, to 25,000. This income he enjoyed with liberality; and he devoted a great part of it to the benefit of his family, and to the purchase of an ample and well-selected library. Thus twenty years of his life were spent in literary assiduity; but in advanced age he found himself reduced, by the suppression of places and pensions, to mere necessities: and these he was obliged to procure by parting with his library. This reverse of condition, however, he supported not only without complaint, but even with gaiety. His celebrated work, "The Travels of the younger Anacharsis," had been the labour and amusement of thirty years; its plan was laid in 1757, and it was published in 1788. It was received with universal applause, and in consequence of it he was admitted into the French academy by acclamation. Declining the office of king's librarian, which was offered to him in 1790, he continued to employ himself in the cabinet of medals, which had been augmented under his direction, so as to have doubled its number of ancient medals. It was his wish to have published a catalogue of its treasures, with suitable engravings, for the information of the learned throughout Europe; but though he had obtained, in 1787, the concurrence of the ministry, the embarrassment of the finances, and the critical events that distressed the country, prevented the execution of this favourite project. In 1792, the infirmities of age crowded upon him; and the calamities of the times, which a person of his age and character might have hoped to escape, aggravated his other complaints. Having been denounced under pretence of the crime of aristocracy by a clerk belonging to the library whom he had never seen, he was arrested, and removed from the house of Mad. de Choiseul, on the 2d of September 1793, to the prison of the Madelonnettes. With such singular patience did he submit to his fate, that when he was conducted to the cell that had been prepared for him, he quietly reposed. An order, however, was soon issued for his liberation, and he was awaked out of sleep, and carried back to the house of his kind and liberal patrons. By way of reparation for this unmerited aggression, he was offered the place of chief librarian; but his increasing infirmities were a sufficient apology for declining it. His decay was gradual; but the severity of the winter of 1795 hastened the termination of his life, which happened on the 30th of April, on which day, two hours before his death, he was reading Horace, till the book fell from his cold hands. He then appeared to go to sleep, and in that state expired: having attained to the commencement of his 86th year. His corporeal form is said to have been impressed with an antique

character; and his bust, sculptured by Houdon, and expressive of the simple tranquillity and candour of a great mind, might suitably be placed between those of Plato and Aristotle. The principal work of this truly eminent person is his "Voyage de jeune Anacharsis en Grece," 3 vols. 4to. or 7 vols. 8vo., which details the history, manners, customs, literature, &c. of Greece, under the form of the supposed observations of a traveller Anacharsis, a descendant of the ancient Scythian philosopher of this name. (See ANACHARSIS.) This person (see the author's advertisement prefixed to the work) is represented as visiting Greece in the year 363 B. C. and fixing his residence at Athens, whence he makes excursions, not only to the other Grecian cities, but to Egypt, Asia Minor, Persia, and the islands of the Ægean sea. On this basis of fiction is formed a real and instructive history, supported by the authority of the most approved ancient writers and by citations from their works. The narrative of Anacharsis is addressed to Artamès and Phèdime, a Persian satrap and his lady, whose characters are meant as portraits of the duke and duchess of Choiseul. It is preceded by an introduction, in which is given a rapid but luminous view of the previous history of Greece. The elegance of style, the beauties of narration, and the judiciousness of reflection, render this the first work (says a biographer of approved judgment and taste) in point of entertainment and instruction, that so brilliant a subject has produced. It has added a capital piece to the literary cabinet of Europe, and its value has already been recognised by various editions, and translations into different languages. To the English edition in seven volumes 8vo. is added an eighth in 4to. containing maps, plans, views, and coins, illustrative of the geography and antiquities of ancient Greece. An anonymous writer (see Monthly Review, Appendix to vol. lxxxii.) has suggested, that the learned author of Anacharsis may have taken the hint of his plan from the "Athenian Letters," consisting of the imaginary correspondence of a set of Greek gentlemen, the contemporaries of Socrates, Pericles, and Plato; but in reality the actual correspondence of a society of ingenious persons of the university of Cambridge, who, in this assumed mode, communicated to each other the result of their researches into ancient history, and produced the best commentary on Thucydides that ever was written. However, the abbe Barthelemy having seen this in France, says the English translator, wrote a letter in consequence to M. Deters, a respectable foreign gentleman residing in London, in which he assures him that "it was not till after the publication of his work, that he heard of the Athenian letters; and that chance alone gave him the idea of it." A collection of miscellaneous pieces of the abbe Barthelemy, in 2 vols. 8vo. was published at Paris in 1793. Gen. Diog.

BARTHELEMY, ST. in Geogr. 744, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the district of Lauzun, 2½ leagues north of Tulleins.

BARTHELIUS, GABRIEL, in Biogr. 74, a learned philologist writer of the sixteenth century, was born at Cöthen, in Brandenburg, in 1587, and received his education at Gotha, and in several other academies both in Germany and Italy. His talents and attainments appeared from a very early period. At the age of 12 years he translated David's psalms into verse, and in 1607 he printed a collection of all his Latin poems, written from his 13th to his 19th year. In his 16th year he composed a learned dissertation on the method of reading the Roman authors, and at 18 he wrote a commentary on the Æneis of Virgil. His acquaintance

with the modern languages was extensive, and he made translations from the French and the Spanish. Such was his attachment to literary studies, that he renounced every other employment and retired to Leipzig for the purpose of prosecuting them without interruption; and so numerous were his works, both printed and manuscript, that, according to the account of Mr. Bayle, few clerks in office have transcribed more papers than Barthius. As to his morals they were not very correct, and like many other men of letters he engaged in several literary squabbles. Towards the close of his life, however, he devoted himself wholly to his religious duties: and it appears from his "Silloquies," published in 1654, that he was thus sedulously employed. He died, after having been twice married, in 1658, at the age of 71 years. The chief of his works are his "Adversaria," printed at Frankfort in 1624, fol. comprehended in 60 books, and containing numerous emendations and illustrations of authors, both sacred and profane, to which he added two other such volumes left in MS.; his "Latin version of Æneas Gaza on the immortality of the soul," with an edition of the original joined to the work of "Zachary of Mitylene," Leipf. 4to. 1655; "Notæ in Claudiano," 4to. Frankfort 1650; "Comment. in Statio," 3 vols. 4to. 1664. As he trusted wholly to his memory, and never corrected what he had written, his works abound with mistakes and contradictions. Gen. Dict.

BARTHOLINE, CASPAR, son of a respectable clergyman at Melanoe in Scania, a province of Sweden, and born the 12th of February 1585, gave early signs of an uncommon capacity, which his father took care to cultivate, by giving him the best instruction his circumstances would permit in his own country. Being well grounded in the learned languages, he went, prompted by his thirst for knowledge, to Rostock, Wittenburg, and in succession, to the principal schools in Germany, France, and Italy, travelling generally on foot, his finances not permitting him to use the ordinary conveyances. Having accumulated a vast stock of learning, in languages and philosophy, but particularly in anatomy and medicine, to which his genius peculiarly inclined him, in 1610 he commenced doctor of physic at Basil; and the following year, going to Copenhagen, he was first made professor of the Latin language, and in 1613 of medicine, in the university there. This post he continued to fill until the year 1624, till mindful of a vow he had made, when afflicted with a severe illness, that if he should recover he would dedicate a portion of his life to the study of divinity, he abjured medicine for theology, to which he addicted himself for the remainder of his life; enjoying, with the professorship of theology, to which he was preferred at the university of Copenhagen, a canonry at Roschild. He died July 30, 1629, at Sora, a small town in the island of Zealand, leaving, as we learn from an inscription on his monument at Copenhagen, where he was buried, six sons and one daughter. His publications were numerous; and though not always well chosen as to the subjects, and adopting in them many popular and erroneous opinions since exploded, yet they were of considerable utility by exciting a spirit of inquiry; to which we may attribute some at least of the discoveries in anatomy, and other branches of natural history, made about that time. A complete catalogue of his works is given by Vander Linden, and by Haller, in his Bib. Anatom. & Med. The following will be sufficient to be noticed here. "Anatomicæ institutiones, corporis humani utriusque sexus historiam et declarationem exhibentes." Wittenburg, 1611, 8vo. This work, much improved and enlarged by his son Thomas, has passed through numerous

editions. "Enchyridion physicum, ex prisca et recentioribus philosophis accuratè concinnatum," Argent. 1625, 12mo. "Opuscula quatuor singularia. 1. De unicorni, ejusque affinis et succedaneis. 2. De Lapide Nephritico, et Amulatis. 3. De Pygmæis. 4. De studio medico incloando, continuando, et absolvendo." Hassniæ, 1628, 12mo. "Sentagma Medicum & Chirurgicum, de cauteriis, præsertim potestate agentibus." Hassniæ, 1642, 12mo. Haller. Bib. Med. et Anatom. Eloy. Dict. Lit.

BARTHOLINE, Thomas, the second son of Caspar, was born at Copenhagen in 1616. Equalling, perhaps excelling, his father in genius, learning, and industry, with more ample means for prosecuting his studies, and enjoying a much longer portion of life, his advances in literature and philosophy were proportionably greater. After being well grounded in classical learning at Copenhagen, following the example of his father, he travelled over the greatest part of Europe, conversing with the most learned men in every place he visited, to whom the same acquired by his father gave him ready access. At Leyden, where he commenced his medical studies, he also acquired a knowledge of Arabic under the celebrated Golius. He then went to Paris and Montpellier, and after residing a proper time at those places, to Padua, which he describes in his book "De Peregrinatione Medica" as one of the best anatomical schools in Europe. At Padua he continued three years, imbibing there those stores of knowledge which laid the foundation of his future honours. Returning to Copenhagen, after an absence of eight years, he visited Basil, where he was created doctor in medicine, in 1645. At Copenhagen, he was first made professor of mathematics, and the year following, of anatomy, in which he soon became a shining ornament. But though the science of medicine had engrossed the greatest part of his attention, no small portion of his time had been spent in acquiring knowledge in other branches of philosophy, as well as in philology and antiquities, as appears by his numerous dissertations elucidating those subjects. He very early embraced the doctrine of the circulation of the blood discovered by Harvey, an exposition of which he added to a new edition of the "Institutiones Anatomicæ," published 1651. To the discoveries of Aësius and Pecquet, of the lacteals and thoracic duct, he added that of the lymphatics, of which he published an account in 1653, under the title of "Vasa lymphatica, nuper Hassniæ in animalibus inventa et in homine," Hassniæ apud G. Holst. 4to. These vessels had been seen about the same time by Jolliff and Rudbeck; and Haller, who examined with attention the claims of the several parties, gives to Rudbeck the honour of the invention, but to Bartholine that of having traced and described them with the greatest accuracy. Having filled the chair of professor of anatomy with the highest reputation for fourteen years, he retired in 1661 to his estate at Hogestatt, that he might have more leisure to prosecute his studies. One of his earliest publications from this retreat seems to have been his "Catalogus Operum suorum hæctenus editorum, extat eum observationibus variis de nivis usu medico," Hass. 1661, 8vo. This catalogue, though then very large, was afterwards more than doubled. A complete catalogue of his works was published by Thomas B. one of his sons, in 1681. In 1670, his house, with his large and valuable library, and manuscripts containing embryos of intended works, and large collections for further improving and enlarging those already published, were burnt, and he was again driven into the world. As some compensation for his loss he was made physician and aulic counsellor to the

the king (though it does not appear he was ever much engaged in the practice of medicine), and the university of Copenhagen appointed him chief inspector of their library. Of this accident he gave an account the same year in a small work, intitled, "De Bibliothecæ Incendio, Dissertatio ad Filios," complaining heavily of the malignancy of Vulcan. Among the numerous manuscripts destroyed by the fire, he laments in a particular manner those intended to elucidate his "Antiquitates puerperii variarum gentium, imprimis Romanorum." "Opus (he says in his letter to his sons) varia eruditione, nisi me sefellit opinio, refertum, cuius prima lineamenta duxi annis abhinc triginta et amplius, suafu Cl. Wallæi, qui id argumentum desiderari monuit. Meursius quidem, Græcæ literaturæ interpres celebris, de Græcorum puerperio folia tria olim publici juris fecit, sed nimia brevitate lectorem curiosum fatiare non potest. Ad plura digressus ego, quicquid autorum veterum lectio assidua, quicquid philologorum aliorum observationes, quicquid variarum gentium instituta, mores, ritus, antiquitates suppeditarunt, quicquid ad hoc argumentum illustrandum Ebræi doctores, Græci sapientes, Romani scriptores conferre potuerunt, cum delectu selegi, et suo ordine reddidi, grata et diffusa varietate nascendi tempora percurrens, quid nempe ante nativitatem, quid in puerperio, quid postea actum fuerit. Ornarunt librum iustæ magnitudinis, varæ veterum inscriptiones, et figuræ passim Romæ, Neapoli, Gaëtæ, Florentiæ, in Sicilia magno studio a me collectæ ex rudibus, et doctorum virorum monumentis, si industias exigui temporis fata concessissent, fidem publico exsolvere potuissent. Jam in ipso puerperio fœtus, in partu laborans, extrinectus, Lucinam inimicam nunquam sollicitabit, nec profam nec postvertam. Abiit enim illuc, unde negant redire quenquam." His son Caspar, who had turned his attention to the same subject, and probably copied many of the notes made by his father, in some small degree repaired the accident by adding them with some observations of his own to a new edition of his father's works, which he published in 1676. On which occasion the father writes (see epistle affixed to the work), "eripuit mihi Vulcanus argumentum bene de publico mendi, ut tibi occasionem præberet caligine profundæ vetustatis obductam materiam propulandi. Ex meo infortunio, tibi gloria relicta videtur. Quemadmodum Saturnus in cælo Paganorum cedere coactus est filio Jovi, &c." The respect, however, that was every where paid him, and the letters of condolence he received from his numerous and learned correspondents, seem to have soon consoled him; as there scarce appears to have been any intermission in his labours, every year almost to the end of his life producing some new publication. The titles of a few of his dissertations, in addition to those already named, are here given; for the rest, the reader is referred to Vander Linden de Scriptis Medicis, but particularly to Haller's Biblioth. Anatom. the Bib. Med. Pract. et Chirurg. in which ample lists of the titles of the works, of the different editions they passed through, and analyses of the contents of the most valuable of them, will be found. "Anatomica Aneurismatis dissecti historia," Panormi, 1644, 8vo. "De Angina Puerorum Campaniæ, Siciliæque epidemica," Neapoli, 1646, 8vo. "De Luce Hominiæ et Brutorum," Leidæ, 1647, attempting to account for the emission of light by putrid flesh. In a later edition he adds, "et de raris et admirandis herbis, quæ noctu lucent." "Domus Anatomica Hassniensis," containing a catalogue of the anatomical preparations, machines, &c. contained in his cabinet, 1662, 8vo. "Centuria quatuor epistolarum medicarum," containing his correspondence with the most celebrated men of the age in which he lived. This valuable collection has been completed, and republished at the

Hague in 1740, in five volumes, 8vo. "De insulitis partibus humani visus," Hassniæ, 1664, 8vo. "A collection of histories of fœtuses voided by the navel, manus, et peros etiam, si diis placet." "Historiæ Anatomiciæ, Cent. vi." Two centuries, forming two small volumes, were published at a time. Though some of the observations, taken on the credit of other relaters, are apocryphal, and should not have been admitted, the number of authentic and curious articles contained in these volumes have stamped a value on them which time is not likely to obliterate. The last work we shall mention is the "Acta Medica et Philosophica Hassniensis," of which four volumes in 4to. were published by him, the fifth and last volume by his son. He began making this collection, which contains many of his own productions but a much larger proportion from correspondents, soon after his return to Copenhagen, driven there by the destruction of his library. As in all similar collections, amidst some very valuable articles many insignificant and useless pieces will be here found. He died in 1680, leaving five sons and three daughters. Two of the sons, Caspar and Thomas, treading in the steps of their father, "at haud passibus equis," contributed to the collection last named, and left other anatomical and medical works. Of the others we have no account. Haller. Bib. Anat. et Bib. Med. Pract. Eloy. Dict. Hist.

BARTHOLINE, *Erasmus*, a younger brother of Thomas, born at Roschild, August 13, 1625. Following the steps of his father and brother, he travelled through England, France, Germany, and the Low Countries; and having acquired much valuable knowledge in natural philosophy and in medicine, went to Leyden to perfect himself in those studies, where he continued three years. In 1654 he went to Padua, where he received the degree of doctor in medicine. On his return to Copenhagen, he was appointed professor in mathematics, and was rewarded with a seat in the grand council of Denmark. These honourable offices he continued to fill with great credit to the time of his death, Nov. 5 1698. In the Acta Hass. vol. v. he gives an account of a quartan fever, epidemic at Copenhagen in the year 1679, which he cured in himself, as well as in many others, by giving a single drachm of the Peruvian bark on the accession of the fever. In 1661, he published "De Figura Nivis Dissertatio," with the observations of his brother Thomas on the use of snow in medicine; in 1664, "De Cometis," 4to. Hassniæ; in 1674, "De Natura Mirabilibus," also 4to.; and in 1679, "De Aere Hassniensis," Frank. 8vo. Albert, another of the sons of Caspar Bartholine, left behind him a work, "De Scriptis Danorum," which was published by Thomas, at Copenhagen, 1666, 4to.

BARTHOLINE, *Caspar*, eldest son of Thomas, was born at Copenhagen in 1650; and treading in the steps of his father and grandfather, acquired almost equal reputation with them. Though accused of plagiarism, and of assuming to himself the honour of discoveries made by others, yet the merit of possessing genius and industry cannot be denied him. Indeed Haller, who had spoken lightly of him at first, on the authority of Swammerdam and Drelinecourt, treats him some years after (Bib. Med. Pract. v. 3. p. 34.) with more respect, calling him, "Vir acuti ingenii, qui dum ad magnos honores, et locum honoratum in regio ministerio emerit." The early part of his life was passed in travelling over foreign countries for the acquisition of knowledge; and he had the happiness of associating with Ruyth, Swammerdam, Duvency, and other celebrated anatomists, all eagerly engaged in the same pursuit. Being at Rome on his travels, at the age of 22 he published in Latin, a learned and accurate treatise on the flutes, or rather on the wind-instruments in general,

of the ancients, under the title, "De Tibiis veterum, et earum antiquo usu, libri tres." This work first appeared at Rome in 1677, dedicated to cardinal Sigismond-Chigi. The second and best edition was published at Amsterdam, 1679, 12mo. with double the number of copper-plates with which the Roman edition had been ornamented, representing ancient musical instruments from drawings chiefly made from ancient sculpture, which are well executed; and illustrated with quotations from the classics where their use is mentioned. No book of the kind seems to have been written since of equal authority; as recourse has chiefly been had to this little tract, by Pianchini, Bonanni, and others who have written expressly on the subject of ancient musical instruments. In 1678, he was received doctor in medicine at Paris. Returning thence to Copenhagen, he was made professor in medicine at the university there, and was in such high estimation as to be raised by the king, in the latter part of his life, to considerable offices in the state. Besides re-publishing several of the works of his father, and contributing largely to the *Acta Hassniensia*, his own distinct treatises are sufficiently numerous and valuable to entitle him to rank with the celebrated authors of that age. The titles of a few of them follow; the remainder will be found in the *Bib. Anat. and Med. Pract. of Haller*. "Exercitationes medicinalium varii generis, imprimis Anatomiarum," Leid. 1675, 8vo. In the seventh, he gives an account of a styptic efficacious in stopping hemorrhages, taken inwardly. An experiment was tried with it successfully before the king. "De Diaphragmatis structura nova," Paris, 1676, 8vo. Drelincourt claims the honour of this discovery; and, as Caspar B. was only twenty-two years of age when he published this account, Haller seems to decide in favour of the claim of Drelincourt. "De Formatione et Nutritione Fœtus in Utero," Hassnia, 1687, 4to. "Specimen Historiæ Anatomicae Partium Corporis Humani," Hassnia, 1701, 4to. He died early in the last century, but in what year is not known. His brother Thomas was appointed to the professorship of law and history. One work of merit is attributed to him, "De Caulis Mortis a Danis gentilibus contemptæ;" and a dissertation published in the fifth volume of the *Acta Hassniensia*, "De Vermibus Aeti, et de Vermiculis feminalibus." The rest of the family of Thomas are said to have distinguished themselves so as to be appointed to honourable situations; but these perhaps were rather the homage paid to the virtues and talents of their ancestors than to their own merit, as none of their works have been noticed by bibliographers. Vander. Linden. Haller. *Bib. Anat. et Med. Pract.*

BARTHOLOMÆUS DE GLANVILLE, an English writer who flourished about the middle of the 14th century, wrote "De proprietatibus rerum," which was first printed in fol. by Caxton, 1480. It was translated into English by Trevisa, and printed by Wynkin de Worde in 1507, and again by Barthol. fol. 1555. The original has passed through many editions. In the seventh chapter, he treats of all diseases a capite ad calcem; taken, Friend says, principally from Constantine. Haller. *Bib. Med. Pract.*

BARTHOLOMÆ, ST. in *Geography*, a town of Germany, in the circle of Bavaria and provostship of Berchtesgaden, near the Königsee, 13 miles south of Reichenhall.

BARTHOLOMEO DE XONGOPANI, ST. a town of in North America, in the province of New-Mexico.

BARTHOLOMEO, ST. a town of North America, in Mexico and province of Chiapa, chiefly peopled with Indians.—Also, a town of Italy, in the kingdom of Naples, and province of Otranto, 19 miles E.S.E. of Matera.—Also, a

town of Italy, in the kingdom of Naples, and province of Capitanata, 6 miles south of Volturara.

BARTHOLOMEW, ST. in *Biography*, one of the 12 apostles, whose native country was Galilee, is supposed by some writers to have been the same with Nathaniel, one of our Lord's first disciples. It has been generally thought, that he preached the gospel in India; and that he carried thither the gospel of St. Matthew in Hebrew, where Pantænus found it towards the close of the second century on occasion of his peregrination into that country for the same benevolent and laudable purpose. St. Jerome adds, that Pantænus brought this gospel home with him to Alexandria; but this fact is disputed; and St. Jerome is supposed to have mistaken the words of Eusebius, who only says that the Christians of India had preserved that Hebrew gospel till the time of Pantænus. (See Euseb. H. E. lib. v. c. 10. Hieron. de Vir. Illust. c. 36.) It has been also said, that Bartholomew preached in Arabia Felix and Persia; and that, returning by way of the more northern and western parts of Asia, he preached at Hierapolis and in Lycœonia; and that he died at Albana, probably Albana in Albania, on the Caspian sea and confines of Armenia. At this latter place, it is said, that he was flayed alive by Aslyages, brother to Polemon, king of Armenia, from hatred to the Christian religion, which the apostle had induced Polemon to embrace. But the time, place, and manner of his death have not been satisfactorily ascertained. Dionysius the Areopagite cites the writings of Bartholomew; and Jerome (ubi supra, and Pref. in Comment. in Matth.) mentions a "gospel of St. Bartholomew," which pope Gelasius, in his decree, refers to the class of apocryphal books. Of this book there are not any fragments extant; unless, as Mr. Jones (Method of Settling the Canon, &c. vol. i. p. 211.) inclines to think, it was the same with the gospel of St. Matthew, which was used by the Hebrews or Nazarenes. This learned writer infers from the relations of Eusebius and Jerome, that this gospel was that which had been found in India; but that it had undergone many interpolations and additions: for, says he, it cannot be thought improbable that those who heard St. Bartholomew preach and explain this gospel to them, should after his departure rather call it by his name, whom they knew, than the name of Matthew, whom they did not know. Besides, Nicephorus assures us (Hist. Eccles. l. iv. c. 32.), that Bartholomew dictated the gospel of St. Matthew to them from his memory, and did not bring it along with him.

BARTHOLOMÆW, of the Martyrs, a Dominican monk, and archbishop of Braga, was born at Lisbon in 1514, and entered into the Dominican order at the age of 14; on which occasion he renounced his family name of Fernandez, and assumed that of the church in which he had been baptized. Having taught theology for 20 years, he at length, with great reluctance, accepted the charge of the archbishopric of Braga to which he was appointed by queen Catharine. Soon after his appointment, he was deputed, in 1561, to attend the council of Trent, in which he strongly insisted on commencing all reforms with that of the clergy. On his return from the council, he devoted his whole time and revenue to exercises of benevolence. Accordingly, he used to say, "I am first physician to 1400 hospitals, which are the parishes of my diocese." During the famine which afflicted Portugal in 1567, and lasted seven years, the poor of Braga were liberally supplied by the archbishop; and he even extended his donations to those of superior condition who felt the severity of the times. The famine was succeeded by a plague; and on this occasion the archbishop, who remained at Braga and obliged the parish priests to do so likewise,

likewise, contributed in no small degree to the relief and comfort of the distressed. Having, after repeated solicitations for the purpose, obtained leave to resign his archbishopric, he retired to a monastery of his order at Viana, where he spent the eight last years of his life in study and religious exercises; and here he died in 1590. In 1733 he was beatified by Clement XIV. The writings which he left were collected and published at Rome in 2 vols. folio. 1744. *Nouv. Dict. Hist.*

BARTHOLOMEW'S Day, St. in the *Calendar*, a festival of the Christian church, celebrated on the 24th of August. On this day, in the year 1662, the act of uniformity which obtained the royal assent on the 19th of May, took place; in consequence of which about 2000 ministers relinquished their preferments in the church, or refused to accept of any upon the terms of this act. See *UNIFORMITY*.

It was also on the eve of St. Bartholomew in the year 1572, that orders were issued for extending the horrid massacre which had been begun at Paris; in consequence of which the matins of Paris, as this massacre was styled in allusion to the Sicilian vespers, were repeated in Meaux, Orleans, Troyes, Angiers, Toulouse, Rouen, and Lyons: so that in the space of two months, 30,000 protestants were butchered in cold blood; if that expression may be used, in speaking of people influenced by the most detestable passions.

BARTHOLOMEW'S Hospital. See *HOSPITAL*.

BARTHOLOMEW, St. in *Geography*, one of the Caribbee islands in the West Indies, about 25 miles north of St. Christopher's, and in circumference about 24 miles. It was peopled in 1648 by Poincy, the French governor of St. Christopher's; and enjoyed by the French without molestation till the year 1689, when a descent was made upon it by Sir Timothy Thornhill, who ravaged the country, and carried off about 700 of its inhabitants, with their cattle and effects. The English government, however, disapproved of this conduct, and allowed the inhabitants to repossess their island, as subjects of Great Britain. At the peace of Ryswick, it was restored to France; but as long as it continued in their possession, it was a nest of privateers, and it has had fifty English prizes in its harbour at the same time. It was ceded by France, in 1785, to the Swedes. The shores of this island are dangerous, and cannot be approached without a good pilot. The only port in the island is "Le Carenage;" near which stands "Gustavia," the chief town in the colony. This port is situated on the western side, and has excellent moorings; but it cannot admit vessels that draw more than nine feet of water. However, it will contain 100 such vessels; in which respect it is superior both to St. Eustatia and St. Christopher. The bay of "Colombier" is deep enough for large ships, but it has no town on its banks; nor had "Le Carenage" any town belonging to it before the island became the possession of Sweden. Its soil is but indifferent, and only a small part of it admits of cultivation; and yet it produces tobacco, cotton, and cassava, and abounds with woods of various sorts. The plantations that most abound are those of cotton, which succeed very well. The practice of the planters is to sow four or five grains of the seed in a hole, and when the plants appear they pluck up all but the strongest. After the first crop, they cut down the branches, and the plant pushes out new shoots, which bear like the original stem; but after the second crop, the seeds must be again sown. The fences of these plantations are aloe trees, which are placed in a straight line, and as close together as possible; and when they arrive at maturity, they are impenetrable either by men or animals. St. Bartholomew also furnishes the neighbouring islands with a peculiar kind of limestone; and its birds

are very numerous. The climate is in general healthy; though at certain times of the year the weather is variable. For nine months in the year it is pleasant; for, though the heat is scorching, the air is cooled and purified by a breeze, which is very refreshing. Hurricanes prevail from the middle of July till the middle of October. The population of this island is much increased since it has belonged to Sweden. At Gustavia are Swedes, English, French, Danes, Americans, and Jews; but the planters are chiefly French. The natives generally live, without being subject to much illness, to an old age. The men are robust, but the women are slight, feeble, and indolent; and are usually attended by slaves, who are employed in keeping off the insects that would incommode them. The houses are made of wood; and some of them are raised upon stone pillars, so that the wind can pass under them. Their windows are mere openings in the sides, with window-shutters or lattices. The inhabitants are supplied with fresh provisions, flour, dried fish, and salted meat from the continent of America. Although this island abounds with mountains, it is destitute not only of lakes and rivers, but even of springs. The fresh water is supplied merely by the rain, and is kept in cisterns; and it is sometimes procured from St. Christopher's, and often at the charge of twelve livres per ton. The chief products for exportation are drugs, cotton, lignum vitæ, and iron-wood. The coins used in this island are the moidore and the piastre; and they have also a fictitious money called the pistovett, worth something more than $\frac{2}{3}$ of a piastre, and a small silver coin called a dogg, and another coin called a bett, of the value of 6 doggs. See "A Voyage to the Islands of St. Martin, St. Eustatia, and St. Christopher, undertaken at the expense of the Academy of Sciences at Stockholm." N. lat. $17^{\circ} 56'$. W. long. $63^{\circ} 11'$.

BARTHOLOMEW, St. an island in the Southern Pacific ocean, being one of the cluster of islands, called the New Hebrides. S. lat. $15^{\circ} 42'$. E. long. $167^{\circ} 17' 30''$.

BARTHOLOMEW'S Island, lies in the straits of Magellan, half a league E.N.E. from Elizabeth island. S. lat. $52^{\circ} 56'$. W. long. $71^{\circ} 4'$.

BARTHOLOMEW'S Island, or *WHERMOYSEN*, is situated on or near the coast of New Guinea. S. lat. $8^{\circ} 13'$. E. long. $138^{\circ} 35'$.

BARTHOLOMEW, St. a parish in Charleston district, in South Carolina, which, by the census of 1790, contained 12,606 inhabitants, of whom 10,338 were slaves. It sends three representatives and one senator to the late legislature.

BARTHOLOMEW, Cape, St. is the southernmost point of Staten land, in the straits of Le Maire, at the south end of South America. To the W.N.W. lies Middl cape, and between them is a bay. To the east of it is a small island.

BARTHOLOMEW is the name of a ledge of rocks, nearly west from the S.W. extremity of St. Mary's island, the largest of the Scilly islands: between which and St. Mary's island, is a channel called St. Mary's sound.

BARTHOLOMITES, in *Religious History*, a religious order founded at Genoa in 1307; but on account of the regular lives of the monks, the order was suppressed by pope Innocent X. in 1650, and their effects were confiscated. In the church of the monastery of this order at Genoa is preserved the image which, it is pretended, Christ sent to Abgarus.

BARTISCH, GEORGE, in *Biography*, surgeon and oculist at Dresden, born at Königsberg about the middle of the 16th century, is said to have invented a speculum to fix the eyelids while performing an operation on that organ: which was improved by Verduyn, and still further by Ruyssch or Rau, for they contended for the honour attached to it.

He wrote a treatise on the diseases of the eyes, in the German language, published at Drefden in fol. 1583. It has since been translated into Latin, and passed through several editions. There are many plates: those representing the different parts of the eye are taken from Vesalius. Infected with the superstition of the age in which he lived, he attributes some of the disorders of the eye to witchcraft. Hal. Bib. Chr. Eloy. Dict. Hist.

BARTLEMEW BAY, in *Geography*, lies on the coast of Kent, without the North Foreland, between that and Ramsgate.

BARTLET, a plantation of America, in Hillsborough county, New Hampshire, containing 248 inhabitants.

BARTMEISE, in *Ornithology*, the name of the bearded titmouse, *parus biarmicus* in Frisch. Hist. Birds.

BARTOLET, in *Biography*. See **FLAMEEL**.

BARTOLI, DANIEL, a learned Jesuit, born at Ferrara in 1608; author of many profound and useful works, written in Italian, with a precision and purity of style which have inclined his countrymen to rank him among the first scientific writers in their language. The great historical work of Bartoli appeared in 6 vols. folio, printed at Rome in succession from 1650 to 1673. After the life of St. Ignatius, he begins with the establishments and labours of the Society in Asia, comprised in 3 vols. and divided into those of the East Indies, Japan, and China. In two other volumes he treats of England and Italy. This performance was translated from the Italian into Latin by father Giannini, and printed at Lyons. He published at Bologna, in 1680, a work in 4to. intitled, "Del suono de tremori armonici e dell' udito" (of harmonical vibrations of sound and of the ear). In this truly scientific and ingenious work are to be found several discoveries in harmonies, that were pursued by posterior writers on the subject. It contains four dissertations; the first treats of the similarity between the circular undulations occasioned in still water when a stone is thrown into it, and the propagation and motion of sound. The second, of the motion of sound compared with that of light: of echoes, or reflection of sound, and of its augmentation in a whispering room or gallery. Third, of harmonic vibrations, and ratios of sound; of sympathetic sounds; of the breaking a glass with the voice. Fourth, of the mixture of sounds; of consonance; harmonics; and the immense increase of sounds in a vessel, or inclosed place, by repercussion. With many other curious enquiries; and ends with the anatomy of the ear.

BARTOLI, Pietro Sante, called *Perugino*, an engraver of reputation, was born at Perugia about the year 1635, and resided chiefly at Rome, where he died in 1700. He is mentioned as a painter, but his character as an engraver is more established. He drew in a correct, agreeable style; and his plates, which are chiefly etched, are executed in a free, masterly manner. His distinguishing excellence consisted in copying the bas-relief, and other works of the ancients. His manner is original; and though his name is not always marked at full length upon his plates, they are easily distinguished by persons acquainted with his works, as the freedom and lightness of his pencil cannot easily be counterfeited. Among his detached prints are: "St. Charles kneeling, accompanied by an Angel," from Antonio Caracci; and the "Adoration of the Shepherds," from Annibale Caracci. Stutt.

BARTOLO, a lawyer of the 14th century, was born in 1313 at Sassoferrato, the ancient Sentinum, in the marches of Ancona, pursued the study of the law at Perugia and Bologna, and attained to such eminence, that he was distinguished by the pompous titles of "Light and

Star of Jurisconsults," "Master of Truth," "Lamp of Right," "Guide of the Blind," &c. In 1339, he was elected professor of laws at Pisa; and after remaining 11 years in the exercise of this office, he removed to Perugia, where he opened a school of law, celebrated through Italy, and frequented by a great number of students. When Charles IV. visited Perugia, in 1355, Bartolo secured his favour to such a degree, that he obtained for Perugia all the privileges usually granted to universities, and for himself the titles of counsellor, and domestic counsellor of the emperor, with permission to bear the family arms of the king of Bohemia. Bartolo is said to have acquired great wealth, and to have died at Perugia in the year 1359; but the time of his death is not precisely ascertained. He was of a feeble constitution, and his temperance was such that he is said to have weighed his food. His learning and researches were extended beyond his own profession, and his regard for the scriptures induced him to make the Hebrew language the object of his particular attention. His works, comprehended in 10 vols. folio, were printed at Lyons in 1545. Nouv. Dict. Hist.

BARTOLOCCI, JULIUS, a Cistercian monk, was born at Cellano in Abruzzo, in the year 1613, and became famous for Hebrew and Rabbinical learning. Having been 36 years professor of Hebrew in the college of Neophytes at Rome, and also Hebrew writer in the Vatican, he died in 1687. His great work is intitled, "Bibliotheca Magna Rabbinica de Scriptoribus et Scriptis Hebraicis," 4 vols. folio. It was printed by the college "Propaganda," and the volumes appeared successively in 1675, 1678, 1683, and 1693. The fourth volume was completed by his scholar Imbonati, who, in 1694, added a fifth, intitled, "Bibliotheca Latino-Hebraica." This work furnishes valuable materials for assisting the interpreters of the Hebrew scriptures. Bartolucci left also annotations on the book of Tobit. Moreri.

BARTOLOMEO, BACCIO. See **BACCIO**.

BARTOLOMEO, Breenberg. See **BREENBERG**.

BARTON, ELIZABETH, called commonly "The Maid of Kent," was an enthusiastic impostor, first known in 1525, as a servant at Aldington in Kent. Being subject to hysterical fits, which were attended with a variety of agitations and distortions, the superstitions of the age led the common people to believe that she was supernaturally inspired. Masters, the parson of the parish, thought that she was a fit person to be employed in order to support the declining cause of Rome, or to give celebrity to his own chapel, and accordingly resolved to exhibit her as a prophetess. With this view, he and some of his friends took her under their tuition; and taught her to act her part so well, that she not only deluded the common people, but imposed on the credulity of several persons of rank and learning; among whom were sir Thomas More, Fisher bishop of Rochester, and Warham archbishop of Canterbury. The monk and ecclesiastics, who were appointed by the latter to investigate this business, made a favourable report, and encouraged the imposture. The nun, for such was the character she had now assumed, was conducted in triumphal procession, and attended by a mob, to the chapel of the Virgin at "Court of Street;" and when she appeared before the image of our lady, she fell prostrate in one of her trances, delivering rhymes, speeches, &c. all of which tended to the honour of that saint, and of the Popish religion. Having for some time performed in this way, very much to the honour and profit of her employers, she was further instructed to denounce menaces against the king on account of his divorce from queen Catharine, and his marriage of Ann Boleyn, and also his enmity to the church, and to declare his subjects ab-

lolved.

solved from their allegiance. Henry, who had for some time despised the imposture and its abettors, being at last jully incensed, issued an order that, in November 1533, the maid and her accomplices should be apprehended, and brought into the star-chamber; all of whom, upon their examination, confessed the imposture, and afterwards publicly confirmed their confession before the people at St. Paul's cross. Some attempts having been made to induce the nun to retract her confession, measures of severity were adopted, and an act of parliament was passed (25 Hen. VIII. c. 12.) which attainted them of high treason, for a conspiracy against the crown and life of the king. Accordingly Elizabeth Barton, and five of her accomplices, were beheaded at Tyburn in April 1534; the deluded nun, who was a simple and ignorant woman, having made a previous acknowledgement of her crime and the justice of her sentence. *Biog. Brit.*

BARTON-upon-Humber, in *Geography*, a large market-town in Yarborough hundred, Lincolnshire, England, 34 miles from Lincoln, and 167 north from London. It consists of several streets irregularly built, and has two large churches. By an ancient register this appears to have been a much more considerable and extensive place than at present; but the destructive plague which infested it in the reign of queen Elizabeth, may, in a great measure, have caused its declension. The most easy passage to Hull is from Barton-Ferry. The market is held on Monday; and it has a fair for horses, oxen, and sheep. At Horklow, in this neighbourhood, was lately discovered a curious Roman tessellated pavement, which is particularly described by Mr. Lysons, in the first part of "*Reliquiæ Romanæ*." This town includes 412 houses, inhabited by 1709 persons. N. lat. 53° 40'. W. long. 0° 22'.

BARTON, a township of Orleans county, in the state of Vermont, America, formerly in that of Orange, lies S.W. of Brownington; 6 miles S.W. by W. from Willoughby lake, and 140 N. easterly from Bennington.

BARTON, in Devonshire, and the west of England, is used for the demesne lands of a manor. Also for the manor-house. And, in some places, for out-houses, fold-yards, &c.

BARTRACH, in *Geography*, an island in the bay of Killala, at the mouth of the river Moy, about 2 miles long, and half a mile broad; 2 miles N.E. of Killala.

BARTRAMIA, in *Botany*. See **TRIUMFETTA**.

BARTSA, in *Geography*, a town of Hungary, 14 miles N.N.E. of Szeben.

BARTSENLU, a town of Asiatic Turkey, in the province of Natolia, 32 miles S. of Kutaia.

BARTSIA, in *Botany*, a genus of plants so named by Linnæus, in memory of his friend Dr. Bartsch. It is an intermediate genus between *rhinanthus*, *euphrasia*, *melampyrum*, and *pedicularis*; distinguished by its coloured calyx. *Lin. gen.* 739. *Schreb.* 996. *Juss.* 100. Class, *dichnami angiospermia*. Gen. char. *Cal.* perianth one-leafed, tubular, permanent; mouth obtuse, two-lobed; lobes emarginate, coloured at the top. *Cor.* monopetalous, ringent; upper lip erect, slender, entire, longest; lower, reflex, trisid, obtuse, very small. *Stom.* filaments four, brittle-shaped, the length of the upper lip; two somewhat shorter. *Anthers*, oblong, approximating under the top of the upper lip. *Pist.* germ ovate. *Style*, filiform, longer than the stamens. *Stigma*, obtuse, nodding. *Per.* capsule ovate, compressed, acuminate, two-celled, two-valved; partition contrary to the valves. *Seeds*, numerous, angular, small.

Ess. Gen. Char. *Cal.* two-lobed, emarginate, coloured. *Cor.* coloured less than the calyx; upper lip longest. *Capf.* two-celled.

Species, 1. *B. coccinea*, red bartsia. *Kalm It.* 3. 100. *Hort. Cliff.* 325. 1. *Amæn.* 1. 160. *Pedicularis*, *Pluk.* *Horminum*, *Morris.* "Leaves alternate linear, two-toothed on each side." This is a very beautiful plant, with a stem entirely simple. Leaves divided, crowded towards the top into a spike, having a single flower on each leaf. Calyx tinged towards the tip of a very deep red, as are also the trisid bractes. Capsule clastic. The fructification is not yet well ascertained. It has been found in Virginia, Maryland, and New York.—2. *B. alpina*, alpine bartsia. *Hudf. With.* *Smith Eng. Pot.* t. 361. *Flor. Dan.* 43. *Euphrasia rubra*, &c. *Ray Syn.* 285. "Leaves opposite, heart-shaped, bluntly serrated; anthers hairy." *Smith.* Root perennial, creeping; stems from four to eight inches high, erect, simple, square, hairy; leaves opposite, sessile, ovate or cordate, serrate, rugose, hairy on the under side, those near the top coloured: spike terminal, purple, leafy; calyx viscid, hairy, purple, its segments nearly equal, acute; corolla of a violet purple, thrice as long as the calyx, compressed, clothed with glandular viscid hairs; lower lip reflexed; anthers prominent, very hairy; style hairfute, projecting beyond the stamens; capsule ovate, downy, of two valves, with a transverse partition arising from each; seeds numerous, angular, small. This rare plant prefers a moist stony soil in alpine situations; it has been found in Westmorland, Durlham, and in the highlands of Scotland.—3. *B. viscosa*, yellow viscid bartsia. *Hudf. With.* *Light. Smith.* *Dickf. D.* p. 72. *Euphrasia major lutea*, &c. *Ray Syn.* 285. "Leaves serrate, uppermost alternate; flowers distant, lateral." Root annual, fibrous; stem about a foot high, commonly simple, unless very luxuriant; erect, smooth, downy, leafy; leaves sessile, ovate-lanceolate, serrate, nerved, scabrous, lower ones only opposite; flowers axillary, subsessile, solitary; calyx tubular, hairy, regular, white at the base; corolla twice the length of the calyx, yellow, divisions of the lip obtuse, nearly equal; anthers hairy; style hairy; capsule ovate, roundish, rough at the apex, the two valves furnished with transverse partitions; seeds numerous, very small, subangular. The whole of this plant is viscid or clammy. It has been found in Cornwall, Devonshire, Lancashire, and in Argyleshire, in marshy soils, flowering in July and August.—4. *B. pallida*, pale-flowered bartsia. *Amæn.* 2. 356. *Gmel. Sib.* 3. 201. n. 11. t. 42. "Leaves alternate lanceolate, quite entire; floral leaves ovate, toothed." Root fibrous; stem round, simple, somewhat streaked; downy towards the top; leaves sessile, linear-lanceolate, three-nerved, longer than the internodes; the lower ones smaller, undivided; the upper longer, broader, with an oblong tooth on each side; floral leaves involving the calyxes, not longer than the flowers, but broader, coloured, more obtuse, trisid or quinquesid; spike terminating leafy, a little inclining to one side; flowers alternate, sessile; corolla purple. A native of Siberia and Hudson's bay, from whence it was introduced into the Kew garden in 1782.—5. *B. gymnandra*, lagotis glauca. *Gartn. in Nov. Com. Petrop.* 14. p. 534. t. 18. f. 2. *G. borealis*, *Pall. It.* 3. 710. t. A. f. 1. *Veronica*, *Gmel. Sib.* 3. 219. n. 33. "Two-stamened; leaves radical, twofold, petioled; stem mostly two-leaved, one-spiked; spike linear, obtuse; whorls bracted, collected." Stem four inches high, smooth, round, simple; root-leaves succulent, oval, entire, or serrate, very smooth; in the middle of the stem they are alternate, ovate, sessile; spike of collected whorls; bractes ovate, bluish; calyx compressed, three-toothed; corolla pale blue, lower lip bisid or trisid; capsule four-toothed. This species, which is very variable in the size and form of the leaves, grows within the arctic circle, on the north side of the frozen rocks

in Kamtschatka, where there is no other vegetation.—
6. *B. Odontites*, red bartha. Hudf. 268. Smith. Brit. 648.
Euphrasia odontites, Sp. Pl. With. Balt. Curt. Lond. f. 1.
t. 44. "Leaves lanceolate, ferrate, the upper alternate;
flowers in racemes, inclining to one side; anthers smooth;
root fibrous, annual." Stems branched, square; leaves
ferrate, lanceolate, ferrate, scabrous, inferior ones opposite;
racemes terminal, many flowered, leafy; flowers all on the
same side; calyx purple, hairy, sometimes quinquefid; co-
rolla rose-coloured; helmet entire, lips cut into obtuse
equal parts; anthers smooth; capsule somewhat compressed,
hairy; seeds numerous, small, striated. Common in mead-
ows and pastures, flowering in July and August.

BARTUS, in *Geography*, a town of Hungary, 16 miles
N. W. of Palotza.

BARUCH, in *Scripture Biography*, was the son of Neriah,
of the tribe of Judah, and the faithful disciple and servant
of the prophet Jeremiah, who employed him as his secretary
or amanuensis. This prophet, having received orders, in
the reign of Jehoiachin king of Judah, whilst he was in
prison, to write all his prophecies till that time, dictated
them to Baruch, by whom they were read to the people
assembled in the temple on occasion of the feast of expiation,
B. C. 605. Baruch, terrified by the threats contained in
the roll which he had read to the people, was encouraged
by an assurance, that, notwithstanding all the calamities
which would befall Judah and Jerusalem, he should obtain
a deliverance. (Jer. xlv.) Archbishop Usher and Dr.
Prideaux are of opinion, that this roll was read a second
time to the people, in the fifth year of Jehoiachin, B. C.
604.; after which it was committed to the flames by the
king himself; and the Jews keep an annual fast, even to
this day, in commemoration of the burning of the roll:
the day marked for it in their calendar is the 29th day of
Cisleu, the ninth month of the Jewish year, and correspond-
ing to our November. After the burning of this roll, an-
other was immediately written, by God's special command,
from the mouth of the prophet, by the hand of Baruch;
and to this were added many other words, and particularly
that prophecy with respect to Jehoiachin and his house,
which is denounced against them for this impious fact, in
the 30th and 31st verses of the 36th chapter of Jeremiah.
In the fourth year of Zedekiah (B. C. 594.), Baruch went
to Babylon with his brother Seraiah, and carried thither a
written account of the prophecies contained in the 50th and
51st chapters of Jeremiah, which denounced the judgments
that were to be executed upon Chaldaea and Babylon by the
Medes and Persians. Baruch, having read these prophecies
to Jehoiachin and the other captives, threw the roll that con-
tained them into the Euphrates, as the prophet had com-
manded him. Baruch accompanied Jeremiah into Egypt,
and after the death of the prophet, he retired to Babylon,
where, according to the rabbins, he died in the 12th year
of the captivity. The book of Baruch, contained in the Apo-
crypha, is an epistle sent, or feigned to be sent, by king Je-
hoiachin and the Jews in captivity with him at Babylon, to
their brethren that were still left in Judah and Jerusalem;
with an historical preface, in which it is related, that Bar-
uch being then at Babylon, drew up this epistle in the name
of the king and the people, by their appointment, and read
it to them for their consolation; and that a collection hav-
ing been made, the epistle with the money was sent to Jeru-
salem. No Hebrew copy of this book is extant; but there
are three other copies, one in Greek and the other two in
Syriac. The Jews have not received this book into their
canon; nor is it found in the ancient catalogues of the scrip-
tures, cited by the fathers and the councils. In the later

catalogues, it is annexed to the book of Jeremiah, and cited
by some of the fathers as a part of Jeremiah. St. Jerome
(Præf. in Jerem.) expressly rejects it out of the canon;
nor does he translate it, because it was not in Hebrew, nor
received by the Hebrews. On the other hand, St. Cyril of
Jerusalem, and the Laodicean council held A. D. 364,
mention Baruch among the canonical books of scripture.
In both the catalogues which they have given, these words
occur: "Jeremias cum Baruch Lamentationibus et Epistola."
But it has been alleged, that by these words they
meant to express no more than Jeremiah's prophecies and
lamentation; that by the epistle, is meant merely the epistle
in the 29th chapter of Jeremiah; and that the name of
Baruch is added, only because he had collected these toge-
ther, and annexed the last chapter, which is supposed to be
Baruch's, the prophecies of Jeremiah ending with the 51st
chapter, as it is positively said in the last words of it; and
it must be acknowledged, says Dr. Prideaux, that as neither
in St. Cyril, nor in the Laodicean council, any of the other
apocryphal books are named, it is very unlikely that by the
name of Baruch, in either of them, should be meant the apo-
cryphal book under this title, which has the least pretence
of any of them to be canonical. Although the church of
Rome has admitted it, and its authority has been sanctioned,
after some hesitation and difficulty, by the canon of the
council of Trent, it is confessed by Protestants to the class
of apocryphal books. Fid. Conn. pt. i. b. i. vol. i.
p. 87, &c. Dupin's Eccl. Hist. vol. i. p. 28.

BARUCO, or **BARICA**, **CAPP**, in *Geography*, is the west-
ern point of Golfo Dulce, or Fresh-water bay, and distant
from it about 4 leagues, on the S. W. side of the isthmus
of Panama, in the Northern Pacific ocean, S. S. E. from
Cabo island, and S. E. from the gulf of Salinas. N. lat.
8° 20'.

BARUD, the name of several small places of Egypt,
on the east and west side of the Nile, situate not far from
Manfalout, Siout, and Dendera.

BARVER, a town of Germany, in the circle of West-
phalia, and county of Diepholz, 6 miles E. N. E. of Die-
pholz.

BARVILISKI, a town of Lithuania, in the palatinate
of Troki, 28 miles S. W. of Troki.

BARULES, in *Church History*, a sect which maintained
that the Son of God had only a phantom of a body; that
souls were created before the world, and that they lived all at
one time.

BARUM, in *Geography*, a town of Germany, in the
circle of Lower Saxony, and principality of Lüneburg;
10 miles south of Lüneburg.

BARUTH, in *Commerce*, an Indian measure containing
17 gauntans; it ought to weigh about three pounds and a
half avoirdupois.

BARUTH, in *Geography*. See **BAIROUT**, and **BERY-
TUS**.

BARUTH, a town of Germany, in the circle of Upper
Saxony, 22 miles S. S. E. of Potsdam, and 34 N. E. of
Wittenberg.

BARWICK, **PETER**, in *Biography*, of a respectable fam-
ily of Wiltshire in Westmorland, was at a proper age
admitted of St. John's college in Cambridge, where, in
1642, he took his degree of Bachelor in Arts. Quitting that
seminary during the troubles which at that time disturbed
the country, he was entertained at the house of Mr. Sache-
verel of Leicester-shire, as tutor to his son. In 1665, he took
his degree of Doctor in Medicine, and soon after was made
physician in ordinary to king Charles II.; which occa-
sioned him to come to London, where he soon acquired
consider-

considerable reputation for his skill in his profession. He is said to have excelled particularly in his treatment of the small pox, and of putrid and malignant fevers; perhaps following the method recommended by Sydenham in those complaints: but he has left no publications on these subjects. He wrote very ably in defence of Harvey's doctrine of the circulation, at that time much agitated; and M. Carrera attributes to him a treatise, published in London, 1671, 4to. "De iis quæ Medicorum Animum exagitant." But the work by which he is principally known, is the Life of his brother John Barwick, late dean of St. Paul's, written in elegant Latin. It was published in 1721, in large 8vo. by Hilkiah Bedford, and an elegant portrait of the doctor, engraved by Vertue, affixed to it. His defence of the "Eikon Basilike," against Dr. Walker, which was written in the 74th year of his age, "does not only shew," Granger says, "the warmth of his loyalty, but discovers not a little of the peevishness of old age." He died August 1705, in the 85th year of his age, highly honoured and respected by all who knew him. Granger's Biog. Hist. of England. Eloy. Dict. Hist.

BARWICK, JOHN, an eminent English divine of the 17th century, and dean of St. Paul's, was born at Wetherlack, a little village of Westmoreland, in 1612; and being designed for the church, he was sent to school at Sedberg in Yorkshire, where he manifested early indications of genius and piety. In 1631, he was admitted into St. John's college in the university of Cambridge, where he became so distinguished, that he was chosen, at the age of twenty, to manage a dispute relating to the election of a master, which was heard before the privy council; and by his conduct in this business, he acquired celebrity in the university, and was also taken notice of at court, and by the ministry. Having taken several degrees at the university, he bore an active part in the civil war, and made one of a party of horse which conveyed the college plate and a small supply of money to Nottingham, where the king had set up his standard. He also published a tract against the covenant, which was so offensive to persons in power, that he was obliged to retire to London, where he rendered all the service in his power to the royal cause. As he possessed talents that justified confidence, he was employed on various occasions of importance by the king and his friends; and he seems to have been successful in his endeavours to reclaim some persons who had been induced to abandon the cause to which he was devoted. During his majesty's confinement in Carisbrook castle, Mr. Barwick contrived to preserve for him a free intercourse with his friends; and he also concerted a plan for his escape, which however did not succeed. After the king's death, and when the royal cause seemed to be desperate, Mr. Barwick, though in a very weak state, exerted himself in maintaining a daily correspondence with the ministers of king Charles II. This office he was at length obliged to devolve, first on his brother Dr. Peter Barwick, and then on another of his brothers, whom he endeavoured to rescue, at the hazard of his own life, from the danger to which he was exposed in consequence of a treacherous discovery. When Mr. Barwick was threatened with torture if he did not immediately disclose the names of the persons who were concerned with him, he kept the secret with invincible firmness; upon which he was committed to the Tower by an order of council, dated April 9th, 1650. Here he was confined in a close dungeon, and debarred the use of pen, ink, and paper, and of all books except the bible. In this situation he remained many months, during which his diet was herbs or fruit, and water-gruel made of oatmeal or barley, with currants boiled in it, and sweetened with a

little sugar; and yet such was the benefit which he derived from this slender diet, that though he was afflicted with a phthisis, atrophy, and dyscrasy, when he was committed, he recovered beyond all expectation, and grew plump and fat. This fact has been mentioned by many physicians, as a proof of the advantage of temperance even in the most inveterate diseases. After two years' confinement, he was discharged in 1652, upon giving security to appear at any time within a twelvemonth before the council of state. At the expiration of the year, being satisfied by president Bradshaw, who had been dismissed by Cromwell, that neither he nor his friends would be exposed to any danger from the recognition into which they had entered, he again engaged with ardour in public business, and conferred with several persons whom he had drawn over to the king's service, on various schemes for restoring monarchy. He was also employed in conducting the king's correspondence, which he did with secrecy and success; and when a restoration was likely to take place, he was sent over by the bishops to represent to the king the state of ecclesiastical affairs. On this occasion, he was received with expressions of cordial esteem by his majesty, and appointed one of his chaplains. Upon his return he visited the university of Cambridge, and took the degree of Doctor in Divinity. Upon the king's restoration, he was offered a bishopric, which he declined accepting, that the world might not imagine that his extraordinary zeal for episcopacy was owing to any secret hope he might indulge of being made a bishop. Upon this he was promoted to the deanery of Durham, with which he kept the rectory of Houghton-le-Spring, four miles distant from the city. The revenue which he thus acquired, he liberally employed in repairing public buildings, relieving the poor, and maintaining hospitality. In 1661, he took possession of the deanery of St. Paul's; and by his interest with his majesty he obtained two royal grants; one for the repair of the cathedral, to which he himself contributed; and the other for securing its privileges. The king also appointed him one of the nine assistants to the twelve bishops employed in the Savoy conference; and he was unanimously chosen by the clergy in convocation, their prolocutor. His various engagements brought on his old complaint, which was aggravated by renewed application after a temporary recess, and which terminated in his death, Oct. 22, 1664. By his will he bequeathed the greatest part of his estate to charitable uses. As his time was so much devoted to political and public matters, we may well imagine that his writings were not numerous: they consisted only of three sermons; the piece against the covenant, already mentioned; and the life of the bishop of Durham, annexed to his funeral sermon. Many of his letters to chancellor Hyde may be found in Thurloe's Collection of State Papers. Biog. Brit.

BARYGAZA, in *Ancient Geography*. See BAROACH.

BARYGAZENUM PROMONTORIUM, a promontory of India, placed by M. D'Anville at the south entrance of the "Barygazeus Sinus," or the present gulf of Cambaya.

BARYPYCNI, in *Greek Music*. The ancients gave this epithet to five of the eight stable or fixed sounds of their diatrem; namely, the hypate hypaton, the hypate-meson, the mese, the paramese, and the nete diezeugmenon. These four terms, barypycne, mesopycne, oxypycne, and apycne imply the lower fifths or dense sounds; that is to say, the fifths or close intervals, the mean of the fifths, the acute of the fifths, and the widest of the fifths, meaning in the Greek music the hypate, the parhypate, the licanos, and the nete of the tetrachords of the fifths kind. By fifths or close, the intervals of the semitones in the chromatic and quarter tones in the enharmonic, are implied. See *GREEK SYSTEM*.

BARYTES, or ponderous earth; terra ponderosa, *schwererde* Germ. *baryte* Fr.

The English and French names of this earth are derived from the Greek βαρυς, heavy, on account of the high specific gravity of the Ponderous Spar or native sulphat of barytes, which is the commonest form in which this earth appears.

§ 1. Historical notices respecting barytes.

It is to Scheele that Chemistry is indebted for the discovery of this substance in 1774. In his valuable essay on manganese, he informs us that the nitric and muriatic solutions prepared from the native black oxyd of this metal contain besides, an earth differing from all those hitherto known by its strong affinity for sulphuric acid, &c. In 1775 Galin made his analysis of the ponderous spar, and found it to consist of the earth newly discovered by Scheele, and sulphuric acid. Bergman repeated and confirmed the experiments of these chemists, and named the earth terra ponderosa. Morveau proposed the term barote derived from the Greek, which Mr. Kirwan softened into barytes. In this appellation Bergman acquiesced; and it is now adopted by all except the German chemists, who in conformity with their general custom prefer the term schwererde, which is a literal translation in their own language of terra ponderosa. Wiegand and Afzelius contributed to enlarge our acquaintance with this substance; and in 1793, Dr. Hope published his valuable experiments in the Edinburgh Transactions. In 1796, Klaproth augmented our knowledge by his masterly analysis of the native sulphats and carbonats of barytes; and in 1797 Pelletier and Vauquelin gave to the world their able memoirs, confirming the facts already admitted and adding to them many new ones.

§ 2. Method of obtaining pure barytes.

The only way of procuring this earth in a state of sufficient purity for chemical experiment, is to expose crystallized nitrat of barytes in a platina crucible to a moderate red heat till it becomes quite dry and has ceased to give out any vapours: the nitric acid will be wholly decomposed and volatilized, leaving the barytes behind in the form of a greyish white porous mass more or less adherent to the crucible. The nitrat of barytes is obtained either by dissolving the native carbonat of barytes in very dilute nitrous acid; or by heating the native sulphat of barytes in a close crucible with charcoal, and thus converting it into sulphuret of barytes and then treating this with nitric acid, which will dissolve the earth and leave the sulphur behind. A much more economical way however of preparing this earth, is mentioned by Dartigues. (Ann. de Chimie, vol. 40.) Take sulphat of barytes, pulverise it together with charcoal, and expose it for half an hour to a full red heat: by this means the greater part will be converted into sulphuret of barytes. Pour boiling water on the mass, and a clear yellow liquor will be obtained by filtration: add to this, carbonat of soda; and a copious white precipitate of carbonated barytes, four times the weight of the soda employed, will be deposited. This being separated from the solution of sulphuret of soda and washed repeatedly, is to be mixed with charcoal and again heated for about half an hour; the carbonic acid will be for the most part converted into gaseous oxyd of carbon, and the barytes will remain in a caustic state. By a short digestion in boiling water and subsequent filtration, a clear supersaturated solution of barytes is obtained; from which, by evaporation and gently heating in a silver crucible, the pure barytes is readily procured.

§ 3. Chemical and physical properties.

Barytes obtained by the methods mentioned in the preceding section, is a porous mass of a greyish white colour and ea-

sily reducible to powder: its sp. gr. in this state cannot be ascertained with much accuracy: Fourcroy states it at 4, Haassenfritz only at 2.374. It is the most active of the alkaline earths; and from its ready solubility, has been arranged by some modern chemists among the proper alkalis. It has a harsh caustic taste, and acts upon the animal economy as a violent poison. It is destitute of smell. It changes syrup of violets green, and the lemon yellow of turmeric to a brownish orange.

By a strong heat it becomes harder, denser, and acquires internally a blueish green tinge. When strongly urged by the blowpipe or a stream of oxygen gas upon a piece of charcoal, it fuses and is partly imbibed by the charcoal and partly volatilized, communicating a yellow colour to the flame.

Its affinity for water is very considerable. When exposed to the air, it gradually imbibes moisture, swells, and falls to pieces; attracting at the same time the carbonic acid of the atmosphere and becoming mild; hence the necessity of keeping it in dry well-stopped vials. When sprinkled with a little water, it exhibits the same appearances as quicklime, but with greater energy; the mass becomes white, is remarkably increased in bulk, and a large quantity of heat is evolved. If stirred up while hot with an additional portion of water to the consistence of a thin paste, it assumes, as it cools, the state of a solid, made up of confused needle-form crystals; but this by exposure to the air becomes carbonated and falls into powder.

Water boiled upon pure barytes, is capable of taking up half its weight of this earth; the greater part of which it deposits by cooling, in slender delicate crystals implanted into each other, or, by carrying on the process very slowly, in the form of compressed hexahedral prisms terminated by a four-sided pyramid, and of a brilliant satiny lustre. These crystals appear to be composed of 53 parts of water and 47 of barytes. By a boiling heat, they completely liquefy; and at length the water being evaporated a white powder remains behind, which is pure barytes. By mere exposure to the air they become efflorescent, and the earth is found to be carbonated. They are soluble in about 17½ parts of water at the temperature of 60°. The fluid that remains after the deposition of the crystals of barytes retains $\frac{1}{5}$ of the earth in permanent solution, and is called barytic water; improperly, barytic lime water. This solution is perfectly limpid and colourless, has an acid taste, and possesses properties very analogous to lime water. By exposure to the air it becomes covered with a crust of carbonated barytes; and this being removed or falling to the bottom, a fresh crust begins to be formed till the whole of the earth is thus separated from the water.

Barytes, like the other alkaline earths, combines with all the known acids; and the barytic salts thus produced are for the most part readily crystallizable, and are distinguished by the strong mutual affinity of their elements: sulphuric acid in particular is distinguished by it from every other combination.

Among the simple inflammables, phosphorus and sulphur appear to be the only ones capable of uniting with barytes. If alternate portions of phosphorus and pure barytes are put into a strong glass tube closed at one end and exposed to a red heat, the phosphorus melts, sublimes, and combines with the barytes that is in contact with it into a brown fusible mass of a metallic lustre, the phosphuret of barytes. This substance when breathed upon exhales a strong fetid odour, is luminous in the dark, changes gradually by exposure to the air into phosphat of barytes, and immediately decomposes water giving out phosphorated hydrogen gas.

The

The affinity between sulphur and barytes is very considerable. Pure barytes digested in warm water with sulphur will take up more than a quarter of its weight of this substance; being then evaporated to dryness and heated red hot in a crucible, the result is a reddish yellow inodorous mass, sulphuret of barytes. Its properties have been very little examined into, on account of the great ease with which it is decomposed. Sulphuret of barytes has a remarkably powerful attraction for water, is very soluble in this fluid even when cold, but is still more so in hot water. In these cases however a decomposition of part of the water is effected; the hydrogen uniting with a portion of the sulphur, and the oxygen with another portion. The new combinations that take place in this process are very interesting, and having been ably investigated by Berthollet we shall treat of them somewhat at length.

When sulphuret of barytes is thrown into hot water it immediately dissolves, the liquid becomes of a yellow colour and exhales a strong smell of sulphurated hydrogen; a white earthy sediment is deposited, and as the liquor cools a considerable quantity of crystals either acicular, prismatic, or in plates, make their appearance: which being dried by pressure between filtering paper become perfectly white. Thus sulphuret of barytes by the action of water furnishes three distinct products. 1. The earthy sediment is regenerated sulphat of barytes; being produced by the oxygen of the water combining with part of the sulphur into sulphuric acid, and this as soon as formed saturating itself with barytes. 2. The crystals are hydrosulphuret of barytes, a salt remarkable for being the only one of the earthy or alkaline hydrosulphurets that is capable of being crystallized. It is very little alterable by exposure to the air, is easily soluble in water, and is decomposable by the mineral acids with extrication of sulphurated hydrogen gas. Besides being produced in the decomposition of sulphuret of barytes, it may be made in the direct way by passing sulphurated hydrogen gas through a Woulfe's apparatus containing barytes dissolved in water. 3. Besides the sulphat and hydrosulphuret of barytes, there remains from the decomposition of the sulphuret of barytes, a yellow liquor which by the addition of muriatic acid gives out a large quantity of sulphurated hydrogen, and yields at the same time a copious precipitate of sulphur; hence it appears to be sulphuret of barytes, intimately mixed or more probably combined with sulphurated hydrogen.

There are therefore three modes in which sulphur can combine with barytes: the first is simple dry sulphuret of barytes, incapable of uniting with water without decomposition; the second is hydrosulphuret of barytes, crystallizable, soluble in water, and decomposable by muriatic acid without depositing sulphur; the third is hydrosulphurated sulphuret of barytes, soluble in water, not crystallizable, and when decomposed by muriatic acid giving out both sulphur and sulphurated hydrogen.

Barytes, in consequence of its alkaline properties, acts on vegetable and animal matter with great energy; it forms insoluble soaps with oils, corrodes and dissolves muscular fibre, &c.

In the dry way, barytes dissolves flex in the same manner as potash does: three parts of barytes and one of flex being intimately mixed and fused together, produce a yellowish green mass entirely soluble in nitric, muriatic, or acetic acid; from which the flex may be separated in the usual way. In the moist way barytes being mixed with newly precipitated alumine forms a compound insoluble in water, but which is readily taken up by an excess of barytes.

Barytes dissolves certain metallic oxyds, especially those of lead; but these combinations have not been much attended to.

Barytes was for a long time supposed to be a very refractory metallic oxyd. Bergman, Lavoisier, and other eminent chemists adopted this opinion from its great specific gravity, from the greenish hue that it communicates by fusion with the other earths, and from its being precipitable from its solutions in acids by prussiat of potash. But in answer to these surmises it may be remarked, that metals in proportion as they become oxygenated approach to the state of acids; whereas barytes possesses alkali properties in a very eminent degree: and that prussiat of potash when quite pure does not precipitate barytes; this appearance being always occasioned by the presence of sulphat of potash, with which the prussiat is generally contaminated.

Barytes is an active poison to animals; as are most of its salts. It is not made use of in the large way, but is of considerable importance in the laboratory as a test for sulphuric acid and an effectual reagent to separate this substance from all its other combinations.

The order of the affinities to which barytes is subject, as far as they have been investigated, appears to be: in the moist way,—sulphuric acid, oxalic, succinic, fluoric, phosphoric, saccharic, nitric, muriatic, citric, tartarous, arsenic, formic, lactic, benzoic, acetic, boracic, sulphureous, carbonic, and prussic acids, water, fat oil, sulphur, alumine, flex; in the dry way,—phosphoric acid, boracic, arsenic, sulphuric, fluoric, and muriatic acids, sulphur, oxyd of lead, flex, and alumine.

BARYTONO, in *Musik*. See BARITONO.

BARYTONUM, from *βαρυς*, grave, and *τονος*, accent, in the Greek *Grammar*, denotes a verb, which having no accent marked on the last syllable, a grave accent is to be understood.

BARZAURA, in *Ancient Geography*, a town of Asia, in the Paropamisus. Ptolemy.

BARZETO, a town of Italy, in the duchy of Parma, 17 miles S. S. W. of Parma.

BARZIZIIS, CHRISTOPHER DE, in *Biography*, professor of medicine at Padua in the beginning of the sixteenth century, published in 1517, "De Febrium Cognitione et Cura Liber," 4to. Lugduni; "Introductorium, sive Janua ad omne Opus praeiticum Medicinæ," Augusta-Vindeli, fol. 1594; with other works of less note. Haller. Bib. Med. Pract.

BARZOD, in *Geography*, a town of Hungary, and capital of a county to which it gives name, seated on the Hernach, between Cassovia and Agria.

BAS, JAMES PHILIP LE, in *Biography*, a moderate French artist, flourished about the year 1754, by whom we have some excellent prints. His great force seems to lie in landscapes and small figures, which he executed in a superior manner. His style of engraving is extremely neat; and yet he proves the freedom of the etching, and harmonizes the whole with the graver and dry point. We have also a variety of pretty vignettes by this artist; among which are most of those that adorn the Svo. edition of Rollin's ancient history in English, published by the Knaptons in 1754. Of his most esteemed works, the following may be enumerated: viz. "The Works of Mercy," a set of several "Dutch Merry-Makings, Fairs, &c." both from Tenier; "The Italian chase," and the "Milk pot," and also the "Wild boar," from P. Wouvermans; several plates of "Hunting, &c." from Van Falens; the "Sea-ports of France," after Ver-

net; the "Environs de Groningue" and the "Environs de Gueldres," from Ruyssdaal. Strutt.

BAS, JOHN LE, a surgeon and accoucheur of considerable eminence, born at Orleans, was admitted at the academy of surgeons of Paris, in 1756, where he resided. Called upon in 1764 to give an opinion as to the legitimacy of a child born ten months and seventeen days after the death of the supposed father, he decided in its favour; but the cause being referred to another court, the assistance and opinion of Bouvart, Ant. Lewis, Petit, and several other physicians and surgeons, were demanded, who unanimously declared against the decision of Le Bas. This gave rise to a furious literary dispute, in the course of which several pamphlets were written on each side. Le Bas defended the part he had taken, by the authority of Aristotle and Pliny, supported by Schenknius and other modern recorders of extraordinary events, as well as by the decisions of the courts of law in various parts of Europe, which had been sometimes given in favour of births protracted to even more than twelve months, which Le Bas thinks might, and, he had no doubt, had happened. Bouvart and Louis, on the contrary, contending against the authority of these pretended cases of protracted gestation brought by their antagonist, which they do not admit to have been completely proved in any one instance, fix the time of parturition in women to nine calendar months from the time of conception; allowing it may be extended beyond that time ten or twenty days, and denying that in any one well-authenticated case, proof had been produced of a woman's being delivered of a living child later than that period. This opinion is now, we believe, universally established. The following are the titles of the books written by Le Bas on the subject: "Question importante: Peut on déterminer le tems de l'accouchement," Paris 1764, 8vo. "Nouvelles observations sur les naissances tardives," 1765, 8vo.; written in answer to Louis, who had confuted his arguments, and denied the authenticity of the cases brought in support of them. "Lettre à M. Bouvart, au sujet de sa dernière consultation," 1765, 8vo. Bouvart had taken the same side with Louis. "Replique à un ouvrage de M. Bouvart," 1767, 8vo. This is written with much acrimony; the last resource, when defending a bad cause. Haller. Bib. Chirurg.

BAS, in *Geography*, a small island in the English channel, near the coast of France, which has a fort to defend the road, and contains about fifty inhabitants. N. lat. 48° 50'. W. long. 4°.

BAS, *Point de*, is the southern cape of a bay which runs in eastward from Quiberon bay on the south of Vilacer river, on the west coast of France.

BAS en Bassin, a town of France, in the department of the Upper Loire, and chief place of a canton in the district of Monistrol; one league north west of Monistrol.

BAS Relief. See *Basso relieveo*.

BASAL, in *Botany*, the name of an Indian tree, growing about Cochin. Ray's Hill.

BASAG, in *Ancient Geography*, an island of the Indian ocean, near Arabia Felix, according to Pliny.

BASALT, *artificial*, or *black porcelain*, a composition having nearly the same properties with the natural basalt, invented by Messrs. Wedgwood and Bentley, and applied to various purposes in their manufactures.

BASALT, in *Mineralogy*. *Argilla basaltica*, Werner; *figurata trap* of Kirwan.

The colour of this mineral is generally greyish black, more rarely bluish or brownish black; its surface is usually reddish brown, from a partial decomposition. It is found in large masses, composing entire insulated mountains of a somewhat

conical form. Of itself it is destitute of lustre, but not unfrequently contains shining particles of olivin or basaltic hornblende. Its fracture is uneven, passing into fine splintery, sometimes approaching to the even or flat conchoidal. It flies, when broken, into indeterminate rather sharp-edged fragments.

The most usual form of basalt is that of columns, straight or curved, perpendicular or inclined, from three inches to three feet in diameter. These pillars are divided either by simple sections at right angles to their axes, or by articulations formed by the convex end of one piece inserted into the concave extremity of the adjoining one. The forms of the columns are pentangular, hexangular, octangular, rarely triangular or quadrangular. Basalt also sometimes occurs in tables, or in globular or elliptical concentric masses, called by the French *basalte en boules*.

It gives a clear ash-grey streak, is almost hard enough to give fire with steel, and is very difficultly broken. It is generally opaque, though sometimes slightly translucent on the edges. It is remarkably sonorous when struck with the hammer. Sp. gr. according to Bergman, 3; Briffon, 2.864. It is sometimes magnetic.

Before the blowpipe, basalt fuses without addition into a black opaque glass, attractable by the magnet. When heated in a charcoal crucible, according to Klapproth, it fuses into an ash-grey mass, of a dull earthy fracture, and minutely spongy texture, overlaid with grains of iron: it loses in this process 9 per cent. of its weight. In a clay crucible, it fuses into a dense glass, opaque in mass, but transparent, and of a clove-brown colour, in thin splinters.

Its constituent parts, according to Bergman, are;

Silex	—	50
Alumine	—	15
Lime	—	8
Magnesia	—	2
Iron	—	25
		100

The geological characters of basalt, and the various controversies with regard to its origin, and that of the other *Rocks of Secondary Transformation*, will be treated of at large in their proper place. It will be sufficient to mention here, that basalt belongs to the stratified mountains, and that it very rarely contains any petrifications. When in mass, it never incloses any metallic veins; and when it occurs in the form of dykes, in coal strata or metalliferous rocks, it produces a total separation of the ore or coal on each side of the dyke.

It is seldom if ever quite pure, being generally mixed with basaltic hornblende, common hornblende, and olivin; more rarely with zeolite, feldspar, quartz, schorl, and calcareous spar. Mica is sometimes found on its surface, though very seldom penetrating its substance. When mingled with these in considerable proportion, it is easily decomposable into a remarkably fertile clayey loam.

The north-east coast of Ireland presents the most perfect and magnificent ranges of basaltic columns in the world: the celebrated Giants' causeway is an assemblage of many thousand articulated pillars projecting into the sea, at the foot of a lofty basaltic promontory, exhibiting a polygonal pavement somewhat resembling a solid honeycomb. The promontory at Fairhead is a vast colonnade of upright basaltic pillars, the shafts of which are 250 feet in length. Scotland also contains many beautiful specimens of columnar basalt: the little island of Staffa in particular almost entirely consists of basaltic pillars, both vertical and bending. The central district of Auvergne in France, and the northern

parts

parts of Italy at the foot of the Alps, as well as Saxony and Hesse in Germany, are also remarkable for their basaltic columns.

Besides the use of basalt as a material for building and paving, it has of late been employed as an ingredient in the manufacture of glass bottles; it serves instead of more costly substances, and the glass, though black and opaque, has the advantage of being considerably stronger than the common green kind. When calcined and pulverized, basalt is an excellent substitute for puzzolana in the composition of mortar, to which it gives the property of hardening under water. Emmerling. Brochant. Kirwan. Ann. de Chimie.

BASAN, or BASHAN, in *Ancient Geography*, otherwise called *Batanea*, lay north of the tribes of Gad and Reuben, and in the half tribe of Manasseh, and was bounded by Gilead and the Ammonites on the east, by the brook Jabbok on the south, by mount Hermon on the north, and by Jordan on the west. Og was king of Bashan, when the Israelites conquered it. After the Babylonish captivity, it was subdivided; so that only a part was called Batanea or Basan, another part Trabanitis, a third Aurunitis or Ituræa, and some part of it Gaulonitis. It was a country famous for its pastures, and its breed of large cattle.

BASANITE of Kirwan, in *Mineralogy*. See SILICEOUS SCHISTUS.

BASANITES, in *Natural History*, a name given by many authors to the touchstone, used for trying gold, &c. Pliay speaks of a basinites which yielded a bloody juice, and was good against diseases of the liver.

BASANITUS *Lapis*, in *Ancient Geography*, the name of a mountain in Egypt, according to Ptolemy.

BASARUS, in *Natural History*. See TOUCHSTONE.

BASARA, in *Ancient Geography*, a town of Palestine, in Galilee, 20 stadia from Gaba, in the vicinity of Ptolemais. Josephus.

BASARTSCHIK, in *Geography*, a considerable town of Romania, in Turkey of Europe. It is tolerably well built, has broad and clean streets and good trade, and is seated on the river Masitz. N. lat. $41^{\circ} 49'$. E. long. $24^{\circ} 30'$.

BASARUCO, in *Commerce*, a small base coin in the East Indies, being made only of very bad tin. Of this coin there are two sorts, good and bad; the value of the base sort is $\frac{1}{5}$ lower than that of the good. Three basarucos are equal to two rees of Portugal.

BASCANIA, in *Antiquity*, ridiculous or grotesque figures hung up by the ancient smiths before their furnaces, to divert envy.

BASCARA, in *Geography*, a town of Africa, in Biledulgerid. The soil in its vicinity is fertile in grain and fruits, particularly dates, which are excellent.

BASCINNO, a town of Italy, in the kingdom of Naples, and province of Abruzzo Ultra, 4 miles S. S. E. of Teramo.

BASCULUMBAI, a town of Asiatic Turkey, in the province of Natolia; 36 miles east of Pergamo.

BASE, BASIS, in *Architecture*, denotes an assemblage of mouldings constituting the lower part of a column, of a pier, or of a pedestal.

In the Grecian remains of the Ionic order, the lower torus, astragal, or fillet of the base, rests immediately on the upper step of the building; but in those of the Corinthian order, a square plinth is added to the base. This practice is observed in all the Roman works, with the exception of the temples of Veita at Tivoli and at Rome; small circular buildings, in which a plinth radiating to the centre would have had an unightly diminution. Modern architects have universally given plinths to their bases; and the following rules

may be stated from their works: the height of the bases of columns to be half a diameter, those of pedestals, two ninths of the height of the respective column and pedestal; the plinths of the Tuscan and Doric orders, one half the height of the base; and one third in the Ionic and Corinthian. For the particular proportions of the mouldings, we refer to the plates.

The *Attic* or *Atticurgic Base* consists of two torusses and fillets, with an intermediate scotia. (See *Plate XVI.* of *Architecture*; and *Plate I. fig. 1.* from the temple of Jupiter Olympius at Athens; and *fig. 2.* from the temple of Minerva Poha, of the same place.) This base, probably the most ancient of any, is employed in all the Athenian remains of the Ionic and Corinthian orders; in Roman antiquities, it is frequently used in the Corinthian order, and constantly in the Ionic; and it has been adopted in every order by modern architects. It may be observed in this place, that, of the Grecian Ionic bases, the upper torus is frequently fluted. See *Plate I. fig. 2.* and *Plate XXVIII.*

The *Tuscan Base*. The remains of antiquity do not furnish any complete specimen of the Tuscan order; and modern architects have accordingly varied in this order more than in any other: the base, however, has been determined by all to consist of a fillet and torus. See *Plate XIV.* of *Architecture*.

The *Doric Base*. It has been the practice of antiquity to execute the Doric order without a base. The massive strength of this dignified order required no additional stability from a base, the projecting mouldings of which would have embarrassed the comparative narrowness of the mono-triglyph intercolumniation. But modern architects having adopted a column modelled rather on Roman than Grecian proportions, have for the most part, with great propriety, added a base to their slender order. The Doric base invented by Vignola (see *Plate I. fig. 3.*) consists of a fillet, astragal, and torus; all other architects have used the Attic base.

The *Ionic Base*. The base peculiar to this order, as described by Vitruvius (see *Plate I. fig. 4.*), consists of a torus and fillet resting upon two scotias, divided by astragals and fillets. Of this base there is an example in the remains of the temple of Minerva Polias at Priene. (See *Plate XXVIII.*) However, the practice of ancient and modern artists, with few exceptions, has given the Attic base to this order.

The *Corinthian Base* (see *Plate XXIX.*) differs from the Attic, in having two scotias with astragals between the torusses. This base is found in the Pantheon, and in the three columns of the Campo Vaccino. In the other Roman and in the Grecian antiquities of this order, the Attic base is employed.

The *Composite Base*. The composite order has no peculiar base, and uses the Attic and Corinthian bases indifferently. Vitruvius. Stuart's Athens. Desgodetz Edif. de Rome. Arch. di A. Palladio. Regola di J. B. da Vignola.

BASE, *Rudentée*, is that which has its toes cut like cables. BASE, in *Fortification*, denotes the external side of the polygon; or that imaginary line which is drawn from the flanked angle of a bastion to that which is opposite to it.

BASE of a *Figure*, in *Geometry*, denotes the lowest part of its perimeter: in which sense, the base stands opposed to the *vertex*, which denotes the highest part.

BASE of a *Triangle*, is properly the lowest side, or that which lies parallel to the horizon.

Thus, the line AB is the base of the triangle ABC, *Plate III. Com. fig. 38.* Not but, on other occasions, the

the lines, AC, or BC in the triangle, may be made the base.

In a right-angled triangle, the base is properly that side opposite to the right angle, i. e. the hypotenuse.

BASE of a *solid figure*, is its lowest side, or that whereon it stands. Thus, the circular plane DUE is the base of the cylinder ABDE. *Plat. III. Geom. fig. 39.*

BASE of a *conic Section*, i. a right line in the hyperbola and parabola, formed by the common intersection of the secant plane, and the base of the cone.

BASE, *Altern.* See ALTERN.

BASE, in *Gunpow.* See CANNON.

BASE, in *Hydroly*, signifies the bottom of the fluid; and the charge thereon is said to be in base.

BASE, *Diplos.*, in *Optics*. See DISTINCT.

BASE of the *Heart*, in *Anatomy*, denotes the broader or upper part of that vessel, to the sides of which the two auricles are affixed. This is sometimes also called the vertex or head, *caput*; in opposition to which, the lesser or narrower part is called *apex* or *muco*, the point or tip of the heart.

Some also give the denomination *lypi* to the root of the *os hyalis*.

BASE, or BASIS, in *Chemistry*, a term which was applied, by the old chemists, to designate those substances of a fixed, inert, passive nature, which combined with, and were acted upon, by more volatile or active menstria. Thus the alkalis, earths, and metallic oxyds, which form compound salts by uniting with acids, were called the bases of these salts. Modern chemists, though they maintain that in every combination the influx or force of affinity between two ingredients is mutual and equal, have yet retained the term, for the sake of precision, to express either species or families of salts, which differ with regard to the acid, but agree as to the alkali, earth, or metallic oxyd which they contain. Thus salts with a base of potash, include all those species which are formed by the combination of the various acids with the particular alkali potash. Again, salts with an alkaline base comprehend the three families of salts with bases of potash, soda, or ammonia, as distinguished from the other salts with earthy or metallic bases. The utility, therefore, of this mode of expression is evident; for though the compound salts are usually divided into genera, according to their acids, as sulphats, nitrats, muriats, &c. yet it is often desirable to arrange them according to their other element or base, for which the Lavoisierian nomenclature has not particularly provided.

The term base is also used on other occasions as a method of denoting species; as when we say, sulphuric acid is composed of oxygen united with a base of sulphur; the vegetable acids of oxygen and a compound base of hydrogen and carbon. Sometimes also the word base is applied in a more indefinite manner; as in the expression, phosphat of lime is the base of animal bone, azot is the base of muscular fibre: where it means merely the characteristic or principal part.

BASE, Engl. BASSE, Fr. BASSO, Ital. in *Music*, the lowest part in the harmony of a musical composition. We prefer the derivation of the word from *basis*, Lat. to baffle or basso; as the word basis is already naturalized in the use that is made of it in architecture, the base of a pillar. Sir Francis Bacon uses it musically for a deep or grave sound: "In pipes the lower the note-holes be, and the further from the mouth of the pipe, the more base sounds they yield." *Nat. Hist.* N^o 178. And Dryden thus expresses the string of an instrument that gives a base sound:

"At thy well-sharpen'd thumb, from shore to shore,
The trebles squeak for fear, the bases roar."

Dr. Johnson says, base is applied to deep, grave sounds; it is frequently written bass, though the comparative baser seems to require base.

The base is the most important of all the parts of poliphonic compositions, being the foundation upon which all the other parts are built; and it has long been a maxim among musicians, that "if the base be good, the harmony and modulation are seldom defective."

The word base is applied to various purposes in music; as base-viol, principal base, continued base, ripieno base, ground base, thorough base, &c. most of which explain themselves: the rest will be further noticed in their places. But the base to any common chord or part of a chord, called by the Italians *basso principale*, and by the French *basse fondamentale*, is what chiefly belongs to this article, and requires a clear explanation of its use.

A principal or fundamental base, in practice, is that base which carries the common chord of $\frac{3}{4}$, or the chord of the 7th, $\frac{7}{4}$.

In the *Encyclopedie Methodique*, there are rules given of M. Sulzer, for arranging the parts to a low base, which

M. Framery says are excellent; yet he has something to object to every one of them. We shall not dispute with either of those able musical critics, their rules or exceptions; we fear that both will be unintelligible to young composers, and that an experienced composer will hardly consult a dictionary for the arrangement of the several parts in his compositions. All we shall recommend to the young harmonist, or juvenile organist, is to accompany low notes in the base by wide intervals. In common chords, when the base is low in the scale, thirds have a very growling bad effect, particularly on the organ. In filling up the parts with the left hand, when the right hand has common chords or divisions derived from common chords, the left hand should only give the fifth and eighth to the base. For the fundamental and supposed base to the treble scale, major, minor, and chromatic, see COUNTERPOINT, COMPOSITION, SCORE, COMMON CHORDS, and THOROUGH-BASE.

BASSE *Fondamental*. The general acceptance of the term base, in practical music, has been given in the preceding article. We shall now endeavour to trace the history of the fundamental base in theory; which Rameau and his adherents regard as a discovery in music, equal to Newton's doctrine of gravitation in astronomy.

The earliest notice in England of the phenomenon upon which the fundamental base of Rameau has been built, was in the Royal Society, in a paper written by Dr. Wallis "on the trembling of consonant strings," Mar. 1677. N^o 134. p. 839. *Abridg.* vol. i. p. 606.

"It hath long been observed, that if a viol string, or lute-string, be touched with the bow or hand, another string on the same or another instrument not far from it (if in unison to it, or an octave, or the like) will at the same time tremble of its own accord. But I can now add, that not the whole of that other string doth thus tremble, but the several parts severally, according as they are unisons to the whole or the parts of that string so struck." (Here he gives the several divisions into which a string, when caused to sound, divides itself, and a delineation of the forms of the several consonances on a plate; but of these we shall have further occasion to speak hereafter.)

"This was first of all (that I know of) discovered by Mr. William Noble, M.A. of Merton college; and by him shewed to some of our musicians about three years since: and after him by Mr. Thomas Pigot, A.B. of Wadham college,

college, without knowing that Mr. Noble had discovered it before." As we are now only proving a claim, we need cite no more of this paper; at the end of which another paper is referred to (N^o 135. p. 879.), which reference says: "Concerning these phenomena, an exquisite solution is given by Dr. Narcissus Marsh, in Dr. Plot's-Natural History of Oxfordshire."

D'Alembert (*Elémens de Musique*) speaks of Rameau as the discoverer of the harmonics, as well as author of the system built upon them. In the preface to the second edition of his *Elements of Music*, in which he has abridged and methodized the musical tracts of Rameau, he says; "it was Rameau who first began to reduce chaos into order, and throw a light upon the principles of harmony."

"He found in the resonance of a single string or sounding body, the most probable origin of harmony, and of the pleasure which it affords us: he developed this principle, and shewed whence the phenomena of music were derived," &c.

And Rousseau, *Diét. de Mus. art. Harmonic*, says, that "Pere Merfenne and M. Sauveur having found that every sound, though seemingly a simple unison, was always accompanied by other sounds less distinguishable, which formed with it the common chord major; and M. Rameau, setting off from this experiment, made it the basis of his harmonical system, which M. D'Alembert at length took the trouble of explaining to the public."

Rameau himself, in his *Nouveau Système de Musique*, published 1726, says "we have in our nature the germ of harmony, without knowing it. It is however easy to perceive it in the sound of a string, a pipe, &c. in the tone of which there are three different sounds at once." In a note he adds, "this experiment is cited by different authors." But he does not seem to know their names. Rameau's account seems to have been taken from our *Phil. Trans.* quoted above, where it was supposed to be an English discovery. But in p. 17 of his treatise, he refers to Merfenne's *Harm. Universelle*, chap. des Instrumens, p. 209. for the invention; but Merfenne, in the very title of the chapter alluded to, relinquishes all claim to the discovery, by merely promising his readers "to explain many circumstances and properties of motion, natural or forced, oblique or perpendicular, where the ideas and experiments of Galileo are examined."

This puts it out of all doubt who was the first discoverer of this musical phenomenon. But the name of the true claimant does not seem to have been mentioned by any writer in England before the year 1748, when Dr. Smith first published his *Harmonics*; who begins the first section of that scientific work in the following manner. "Sound is caused by the vibrations of elastic bodies, which communicate the like vibrations to the air, and these the like again to our organs of hearing."

"Philosophers are agreed in this, because sounding bodies communicate tremors to distant bodies. For instance, the vibrating motion of a musical string puts others in motion, whose tension and quantity of matter dispose their vibrations to keep time with the pulses of air propagated from the string which was struck. Galileo explains this phenomenon by observing, that a heavy pendulum may be put in motion by the least breath of the mouth, provided the blasts be frequently repeated, and keep time exactly with the vibrations of the pendulum; and also by the like art in raising a large bell; and probably he was the first that rightly explained that phenomenon."

And now, having traced this curious discovery to the fountain-head, we shall draw all further information from that source.

The admirable Galileo, perhaps the most acute and useful experimental philosopher of any age or country, in his first dialogue (*Opera del Galileo*, vol. ii. Bologna 1655.), after discussing the vibrations of pendulums, which he first applied to the measuring of time, proceeds with his friend Sagredo, an intelligent enquirer into mechanical powers, who asks questions of difficult solution; and Simplicius, a young philosopher, curious concerning the causes of common effects. Galileo, under the name of Salviati, after discussing the doctrine of motion, and the range of cannon-balls, says; "vengo ora da i quesiti di V. S. dirvi qualche mio pensiero sopra alcuni problemi attenenti alla musica; and now, at your request, gentlemen, I shall give you my thoughts on some musical problems, a noble subject, on which so many great men have written, and, among the rest, Aristotle himself; concerning which he has left us many curious problems; so that if by such easy and intelligible experiments I shall be able to account for the wonderful phenomena of sound, I may perhaps hope that my reflections would amuse you."

"Sagredo. They will not only amuse me, but are what I most particularly wish for, being extremely delighted with all musical instruments; and though I bestowed much meditation on harmonical consonances, I have always remained perplexed and unable to account for one of these intervals pleasing me more than another. For some not only give me no pleasure, but are extremely offensive to my ear; and that common problem of two strings tuned in unison, when one of them is caused to sound, the other not only vibrates but actually sounds, I still am unable to solve; nor do I clearly understand the forms of consonances, or many other particulars concerning them."

"Salviati. Let us try whether from our doctrine of pendulums we cannot acquire some information concerning these difficulties. And as to the first doubt, which is, whether it be true that the same pendulum performs all its oscillations, whether its swing be the greatest, the mean, or the least, exactly in equal times? I shall depend on what our professor told us, who has clearly demonstrated that a pendulum subtending any arcs whatever, passes them all in equal times, i. e. whether of 180°, or 60, 10, 2, $\frac{1}{2}$ a degree, or of four minutes, supposing them all to terminate in the lowest point, which touches the horizontal plane—all is performed in equal times." This accounts for the tone of a string not sinking or changing as the vibrations become more feeble. Here too he gives the ratio of vibrations; and afterwards the history of his discovering in a church, from the swing of a lamp, the laws of a pendulum, and that all its oscillations were isochronous: This doctrine he applied to the vibrations of musical strings, upon the number of which the gravity and acuteness of sounds more depend than on their length, tension, or thickness. It seems as if few discoveries had been made in the philosophy of sound since this dialogue was written. Galileo has demonstrated that if a string sounding C, for example, be divided by a moveable bridge into half, each half would be an octave to the whole; if divided into three parts, each would be a fifth to the octave; divided into four parts, each would be a fifteenth or double octave to the whole; if into five parts, each would be a major seventeenth (commonly called a tierce or sharp third) to the fifteenth or double octave.

Though these divisions are the same as the ratios ascribed to Pythagoras, and those of Euclid in the section of the canon; and though long before Galileo's time, the chorus of a full organ had been constructed on the principle of the harmonics to a fundamental base, there can be no doubt but that this great philosopher first caught nature in the fact of producing

produced & modified, and without human aid, the sweetest chord in the whole system of harmony.

Here all the phenomena are represented and explained, of kindred things being caused to tremble and found merely by the tremors occasioned in the medium by the tone of a neighbouring string or sounding body.

Here too the theory of tuning strings, not only by tension but by weight, is explained; from which proportions, Doubtless, the lychord of Plinius was tuned by weights instead of tension, some fifty years ago.

Having justly returned to Galileo the discovery of the harmonic proportions into which every single string and sounding body descends itself when caused to sound, it seems unnecessary further to explain this phenomenon here. We shall therefore proceed to the system built on this foundation by Rameau, under the title of *Basse Fondamentale*; concerning which, not only the author, but the French nation, have gloried as much as if he had discovered and conquered a new world in the celestial regions of harmony.

Basse Fondamentale, or *Fundamental Base*, was first formed into a system by Rameau, and though the Italians meant the same thing by *basso principale*, so early as the time of Zarlino, it was not so clearly explained; nor were

its derivation or derivatives, from a physical experiment, then generally known in Italy.

The natural harmony or common chord to every base, consists of the third, fifth, and eighth above the base; or their octaves, which the Germans call the triad: or rather the unison, or any given sound, with its third and fifth, constitute their triad, without the octave. If instead of the fundamental or lowest sound (which Rameau calls the generator) the base takes the third or fifth of that chord instead of the lowest sound or principal base, the harmony is said to be inverted; and the lowest part, carrying the chord of the sixth, or 9, is called the supposed base, and sometimes the *basso continuo*. (See *SUPPOSED Base*, and *BASSO Continuo*.) If any sound is added to the common chord, except the seventh, the base is no longer fundamental.

The fundamental base should move by consonant intervals; as 3d, 4th, 5th, or 6th: never rising or falling one note or degree with perfect and similar harmony to both; as it would occasion a violation of the rule against 5ths and 8ths in succession, and preclude all relation and connection of chord to chord. Common chords may be given to the following fundamental bases in succession.

In a regular ascent or descent of the scale in modern harmony, the rule for accompanying the octave (see *REGLE DE L'OCTAVE*) allows only common chords to the key note and the 5th of the key; which are consequently fundamental

bases: the chords of the 6th and 9th are given to the rest. Rameau (*Traité de l'Harmonie*, p. 190.) has made all the following bases fundamental, by accompanying them with common chords.

By contrary motion, however, the principal base may have, and often has had, common chords with good effect, when ascending diatonically.

nor modes, or keys with flat 3ds. From whatever grave sound the harmonies have been observed to arise, they are all component parts of major chords, or keys with sharp 3ds. In Rameau's *Génération harmonique*, chap. xii. *origine du mode mineur*, where we expected all would be cleared up, we found his derivation of this mode more perplexed and perplexing than any part of his book. He tells us that we are to find indications given by nature of the minor mode below the principal sound, which causes the 12th and major 17th below it to vibrate though not to sound. And M. D'Alembert in the first edition of his "Elements" seems satisfied with this solution. When, after telling us that the 12th and 17th major are produced by every sound immediately after it has been heard in its totality: that is, the tone of the whole string or sounding body. That the 12th and 17th arising from this string or principal sound, are called its harmonics, and form, when approximated for the convenience of the hand, the common chord major or triad of unison 3d and 5th. But to acquire a natural origin of the minor mode, if we tune the 12th and major 17th below any sound, below C for example, which will be an octave below the 5th and a double octave below the inferior major 3d, to C, we shall find when C is struck, that its lower 12th and

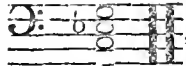

And if the seventh were added to many of these chords, they would be still more interstalling, without diverting the base of the title of fundamental.

Of all the experiments that have been made in physical harmony, there has been no satisfactory origin found of mi-

major 17th will vibrate but not sound . But this

this origin neither satisfied theorists nor practical musicians. And in M. D'Alembert's second edition of his "Elements" he changed his ground, and instead of the chord minor of F,

he adopted that of C: , in which G is an

harmonic of C as well as of Eb. But this solution of the difficulty, fetched from far, and by no means satisfactory, was changed in the article Fondamentale of the 7th volume of the Encyclopedie, to ACE, without succeeding in proving it to be the work of nature.

The abbé Feytaud, in the new Encycl. methodique, says, that F is the fundamental base of A minor. But though among the harmonics of a single base note there is, at the top of the chord, a sound something resembling a 7th, it is not a major 7th; nor can F, or any grave sound, produce a major 7th. All the harmonics produced by F, are the following, and in the following arithmetic order:

1 8 12 15 17 19 21 22.
F f c f a c eb f.
1 2 3 4 5 6 7 8.

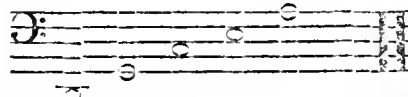

A major 7th may be joined to the common chord of F in practice, without taking from it the title of fundamental; but it is not one of its harmonics; ergo, F is not the fundamental base to A minor. Nor does nature give any indication of a minor chord either in the harmonics, or 3d found produced by two trebles. See TERZA SUONA.

BASE-VIOL. This instrument is now often confounded with the violoncello, though not of the same kind. In the 17th century every musical family had a chest of viols; all with six strings, and the finger-board fretted. The base-viol was the largest of these instruments, and called in England the six-stringed base; but in Italy, viol da gamba, on account of its resting on the leg of the performer. The tenor viol, the next in size of that class, is called viol da braccia, from its resting on the arm or shoulder when played on. The smallest and highest of these instruments is called the treble viol.

A complete chest of viols contained 8 instruments; 2 first trebles, two second trebles, two tenors, and two bases; all strung and tuned alike, by 4ths and 3ds, and the necks fretted. The accordatura of the open strings is as follows.

Treble Viol. 

Tenor Viol;
or, Viol da Braccia. 

Base Viol;
or, Viol da Gamba. 

From the time of queen Elizabeth till that of Charles II., in all private concerts (we had none that were public then) these, except the common flute, were the only instruments that were admitted into a gentleman's house; and indeed from the feebleness of the tone they may very properly be called stromenti da camera, chamber instruments. At first where voices could not be procured the several parts of full anthems, services, and other choral mu-

fic were adapted to viols. The first music that was composed expressly for them was fantasias; the title for which was brought from Italy previous to sonatas and concertos. The passages given to these viols, at this time, discover no kind of knowledge of the expressive power of the bow; and even Orlando Gibbons, who composed so well for voices in the church, seems very little superior to his contemporaries in his productions for instruments. Indeed, his madrigals of five parts, as well as those of many others, are said in the title page to be apt for viols and voices; a proof that with us, as well as the ancient Greeks and other nations, there was at first no music expressly composed for instruments; consequently, the powers of these instruments must have been circumscribed; and when this music was merely played, without the assistance of human voices and of poetry, capable of no great effects. The subjects of Orlando Gibbons' madrigals are so simple and unmarked, that if they were now to be executed by instruments alone, they would afford very little pleasure to the greatest friends of his productions and those of the same period. At the time they were published, however, there was nothing better with which to compare them; and the best music which good ears can obtain, is always delightful till better is produced. Air, accent, grace, and expression, were now equally unknown to the composer, performer, and hearer; and whatever notes of one instrument were in harmony with another were welcome to the player, provided he found himself honoured from time to time with a share of the subject, or principal melody; which happening more frequently in canons and fugues than in any other species of composition, contributed to keep them so long in favour with performers of limited powers, however tiresome they may have been to the hearers when constructed on dull and barren themes. See FANTASIA, SONATA, and CONCERTO.

BASE, in Law.—Base estate is that estate which base tenants have in their lands.—Base fee denotes a tenure in fee at the will of the lord; by which it stands distinguished from socage, or free tenure. (See FEE.)—Base court, is any court not of record. Such, e. gr. is the court-baron.—Base tenure, bassa tenura, denotes holding by villenage, or other customary service; as distinguished from the higher tenures in capite, or the military service.

BASE rocket, veseda, in Botany. See RESEDA.

BASE Knights, bas chevaliers, denote the inferior order of knights as distinguished from barons and bannerets, who were the chief or superior knights.

BASE Point, in Heraldry. See POINT, and ESCUTCHEON.

BASE Ring of a Cannon, is the great ring next behind the touch-hole.

BASEDOW, JOHN BERNARD, in Biography, was born at Hamburg in 1723; and though the early part of his education was neglected by reason of the severity of his father, which obliged him to abscond, and to live almost a year as a domestic with a land surveyor at Holstein, he afterwards returned to his native place, and successfully pursued his studies in the Gymnasium from the year 1741 to 1744, under professor Reimarus. Here his proficiency was such, that he was enabled to subsist at the age of 16 years, independently of his parents. As it was his father's ambition to make his son a clergyman, he went to Leipzig in 1744 for the purpose of studying theology. Here he continued two years, and attended the lectures of professor Crusius. These lectures and the writings of Wolff, which he also perused, unsettled his mind with respect to many doctrines which he had imbibed, and excited some doubts in his mind concerning the truth of the Christian revelation;

but by further examination of this interesting controversy, he became a firm believer of the truth of the divine mission of Christ, though he denied many of those doctrines which some Christians deem to be essential articles of the Christian faith. In 1749, he was appointed private tutor to the son of a gentleman in Hessein; in this situation he had an opportunity of submitting to the test of experience the plan of an improved method of education, which he had for some time held in contemplation. The attempt succeeded to his wish; and though his pupil was only seven years of age, when he undertook the charge of him, he was able in the space of three years not only to read Latin authors, but to translate from the German into that language, and to speak and write it with a degree of fluency. He had also made considerable progress in the principles of religion and morals, in history, geography, and arithmetic. This success advanced his reputation; so that in 1752 he was admitted to the degree of master of arts at Kiel, and in the following year he was chosen professor of moral philosophy and the belles lettres in the academy at Soroe in Denmark. Here he published several works, which were well received; particularly his "Practical Morality for all conditions," containing hints of his improved plan of school education. His lectures on morality and religion were much frequented; but as he spoke with freedom on some points of theology that were generally received, he was removed by the Danish court to the gymnasium at Altona, and allowed the salary which he had enjoyed as professor. In the 40th year of his age he began, in opposition to the advice and remonstrance of his friends, to attack publicly many received tenets of the church, and he published his "Philalcthy," in which he suggests doubts concerning the eternity of future punishment; his "Methodical Instruction in Natural and Revealed Religion," in which he avows his dissent from the common doctrine concerning Jesus Christ, the Holy Ghost, inspiration, baptism, the Lord's supper, &c.; his "Theoretic Syllern of Sound Reason;" and some other works of a similar kind. In consequence of these publications he was represented by Gotze, Winkler, and Zimmermann, clergymen of Hamburg, as holding opinions hostile to revelation, as a man void of principle, and as an enemy to religion. The populace likewise were incensed, and threatened to stone him. He was preserved, however, from becoming a victim to intolerance, by the protection of count Bernhoff and some other friends at Copenhagen. In these circumstances he directed his attention to an improvement of the usual method of school-education; and for his encouragement in the prosecution of it, he was released by the Danish court from attendance at the gymnasium of Altona, and allowed a pension of 800 dollars. Having solicited and obtained considerable subscriptions, he published in 1769 the heads of his "Elementary Book;" which he submitted to the inspection of many respectable and learned friends, by whom it was approved. In 1771, the sum which he had collected amounted to 15,000 rix-dollars; of which a thousand had been contributed by the empress of Russia, who read his plan and invited him to Peterburgh. Although he met with some opposition, he obtained very considerable encouragement; and he was invited by the prince of Dessau, with the promise of a pension of 1100 rix-dollars, to establish the school which he had projected in his territories. Accordingly, he removed to Dessau, which afterwards became the chief place of his residence. Having published several detached parts of his work, he determined in 1772 to continue it. In the following year he published the principles of "Arithmetic and the Mathematics," and in 1774 his grand treatise in four volumes, with 100 copper-plates, under the title of "Ele-

mentary Work," by way of distinction from his "Elementary Book" which he had published in 1770. This publication was favourably received, and was soon translated into Latin and into French. As he had bestowed six years' labour on the completion of this work, his health declined; and in this state he wrote his "Legacy for the Conscience," being a work on the principles of natural and revealed religion. The prince of Dessau, having permitted him to establish his school in any place which he found most convenient, he travelled to Frankfort on the Mayne; and on his 51st birth day, he determined to put his plan in execution, and, on account of its humane object, to give his seminary the name of the "Philanthropinum." "This school was intended to be a seminary for rearing up young teachers and professors, and a pattern for all the other schools of Germany. The children of wealthy parents were to be admitted for the sum of 250 rix-dollars per annum; all the former errors in education were to be carefully guarded against; and the children of poor people were to be educated in it also, either to render them fit for becoming teachers themselves in schools of lower rank, or for being useful servants in respectable families." At Dessau, whither Bafedow returned from Frankfort, on the 27th of December 1774, the 6th birth-day of the hereditary prince of Dessau, he opened his "Philanthropinum," appointing Wolke as head master, and undertaking the direction of it for seven years, promising to read lectures, and to give a few hours' instruction daily to the pupils without any emolument. The plan, however, was not encouraged agreeably to Bafedow's expectations, and he therefore relinquished it. His disappointment and other circumstances led him to seek relief from drinking, by which he impaired his health and injured his reputation. In the melancholy period that elapsed from 1778 to 1783, he employed himself in examining the nature of pure Christianity; and whatever may be thought of his peculiar opinions with regard to some of its doctrines, he appears to have been a friend to truth, and a zealous advocate for religion and virtue. In 1785 he published a plan by which children might be more easily taught to read, and distributed 500 copies of it in various schools. His plan was introduced by himself in two schools at Magdeburg, and it succeeded to his wishes. Having experienced great friendship at Magdeburg, he removed to this city towards the close of his life, and died there in 1790 in the 67th year of his age. Bafedow is represented by his biographers as a man of acute judgement and penetration, and possessed of great sensibility and a lively imagination. His works, which relate chiefly to religious subjects or to education, amount to upwards of 50 different treatises. *Beitraege zur Labersgeschichte, &c.* or Biographical Anecdotes of Joh. Beruh. Bafedow, taken from his own works, and from other authentic sources. 8vo. Magdeburg, 1791.

BASILECE, in *Geography*, a town of Italy, in the kingdom of Naples and province of Capitanata, 7 miles S.S.W. of Volturara.

BASELS, BASELLI, in our *Old Writers*, a kind of coin abolished by king Henry II. 1158.

BASELLIA, in *Botany*. *Lin. gen.* 382. *Reich.* 413. *Schreb.* 520. *Juss.* 84. *Gen. n.* 125. *Class* and order, *pentandria trigynia*. *Nat. Order of Heboracee; Anemifles* *Juss.* *Gen. Char.* *Calyx* none. *Cor.* seven-lobed, pitcher-shaped; two outer divisions broader, one within the rest, converging above, fleshy at the base. *Stam.* filaments five, tubulate, equal, flattened to the corolla, and shorter than it; anthers roundish. *Pist.* germ superior, subglobular; styles three, filiform, of the length of the filaments; stigmas oblong, on one side of the tops of the styles. *Per.* corolla permanent,

manent, closed, fleshy, counterfeiting a berry. *Seed*, single, roundish.

Ess. Char. *Cal.* none. *Cor.* seven-cleft; two opposite divisions shorter, at length berried. *Seed*, one.

Species, 1. *B. rubra*, red Malabar night-shade, *ensis* Lin. hort. Cliff. 39. *Gandola rubra*, Rumph. Amb. t. 154. f. 2. "Leaves flat; peduncles simple." It has thick, strong, succulent stalks and leaves, of a deep purple colour; climbing to the height of eight or ten feet, and producing many side-branches; in the bark-stove living through the winter, and producing great quantities of flowers and seeds. The fruit is a sort of spurious berry, of a very dark red colour, a little flattened, furrowed cross-wise at top, and containing a single nut. A native of the East Indies, Amboina, Japan, &c.; and cultivated, in 1730, by Miller. From the berries a beautiful colour is drawn, but when used for painting, it changes to a pale colour; the juice is said to be used for staining calicoes in India. 2. *B. alba*, white Malabar night-shade, *Gandola alba*, Rumph. Amb. Pluk. Alm. t. 63. f. 1. *Murafakki*. Kæmpf. Amæn. 734. The stalk smaller, the leaves oblong and flaccid, and the flowers and fruit smaller than in the foregoing. Miller raised from seeds, sent by Jussieu, two varieties; one with purple leaves and stalks, the other having leaves variegated with white. Cultivated by bishop Compton in 1691. A native of China and Amboina. 3. *B. lucida*, shining Malabar night-shade; "leaves subcordate; peduncles crowded, branching." A native of the East Indies. 4. *B. nigra*, black Malabar night-shade; "leaves round-ovate; spikes lateral." Stem perennial, twining, slender, round, succulent, branched; leaves thick, smooth, entire, alternate, petioled; flowers purple and white, lateral, few, in long, solitary spikes. Calyx three, roundish, acuminate, very small scales; corolla one-petalled, with a short swelling tube, and a six-cleft border; germ four-lobed; styles shorter than the stamens; berry roundish, deep black, small, four-lobed, with four blunt concave clefts at top. Loureiro apprehends, that the berry is formed from the germ, and not from the corolla. He thinks that this plant is the same with the "*Gandola alba*" of Rumphius; but different from the *B. alba* of Linnæus. Perhaps none of these are specifically distinct. A native of China and Cochin, in the hedges and fences of their gardens.

Propagation. These plants are propagated by seeds, sown on a hot-bed in the spring, and planted, when fit to remove, each in a separate pot, filled with rich earth, and plunged in a tan-bed, where they must be treated like other exotics. They may be also propagated by cuttings, which should be laid to dry for a day or two after being separated from the plant, before they are planted, that the wound may heal; otherwise they will rot. These should be treated in the same manner with the seedling plants. These plants flower from June to autumn, and the seeds ripen in September and December. Martyn's Miller's Dict.

BASELLI, BENNET, in *Biography*, son of Mark Baselli, physician of Bergamo, a town in the Venetian territories, studied anatomy and medicine at Padua, assisted by Fabricius ab aqua pendente, and other celebrated masters, under whom he is said to have made great proficiency in the knowledge of his profession. Returning to Venice in 1594, he was refused admission into the college of physicians there, on account of his practising surgery jointly with medicine. Irritated by the injustice, as he thought it, of the law by which he was rejected, he published at Bergamo, in 1604, a defence of surgery, under the title of "*Apologie, qua pro chirurgiæ nobilitate strenue pugnatur, libri tres*, 4to. Floy. Dict. Hist.

BASEMENT, in *Architecture*. Stereobata. Stylobata.

Soubassement, Fr. The lower part or story of a building when it is in the form of a pedestal, with a base or plinth die, and cornice or plat-band.

In the Roman antiquities, the temples are generally raised on a basement which has exactly the members and proportions of a pedestal to the columns of the portico; but in modern architecture, the basement constituting the lower story of a habitation has its proportions regulated by the nature of the apartments which it contains. The Italian palaces have frequently the summer habitations on the basement, which in that case is often as high as the principal story; but when it only contains offices, it sometimes does not exceed one half of that height. These proportions may be considered as extremes, which it will not be proper to exceed; for the principal story loses its importance when too much elevated, while a very low basement will not admit any tolerable proportions of windows and doors.

Basements are commonly decorated with rustics of various kinds; they are crowned with a cornice or plat-band, and supported on a base or socle. The height of the rustics, including the joint, should never be less than one module of the order of the principal story, neither should it much exceed this measure; the plat-band should be the same height as a rustic, and the socle or plinth rather more. When the basement is finished with a cornice, it should also have a regular moulded base; the height of the cornice may be about one seventeenth of the whole basement, and the base about twice as much. Chamber's Civil Architecture. Desgodetz. edif. de Rome.

BASENTELE, in *Geography*, a town of Italy, in Calabria, where the emperor Otho II. was vanquished and made prisoner.

BASHARIANS, a sect of Mahometans, being a branch or subdivision of the Motazalites.

The Basharians are those who maintain the tenets of Bahar Ebn Motamer, a principal man among the Motazalites, who varied, in some points, from the general tenets of the sect, as extending man's free agency to a great length, even to the making him independent. He asserted, that God is not always obliged to do that which is best; for that, if he pleased, he could make all men true believers. Accordingly he taught, that God might doom an infant to eternal punishment; but taught at the same time, that he would be unjust in so doing. These sectaries also held, that if a man repent of a mortal sin and afterwards return to it, he will be liable to suffer the punishment due to the former transgression. Vide Sale's Prelim. Disc. to the Koran, p. 162.

BASHAW, PASCHA, or PACHA, a Turkish governor of a province, city, or other district. The Arabs pronounce it Bashaw; but the word is Turkish, and properly Pashaw, denoting viceroy; whence is derived Pacha. As some of the provinces of the Turkish empire are too extensive for the government of the Pacha, this officer has a variety of sub-delegates; but it is in reality the sultan who dictates and commands, under the varied names of Pacha, Motfallam, Kaiem-Makam, and Aga; nor is there one in this descending scale, even to the lowest Delibashe, who does not represent him.

All Egypt is, on the part of the grand seignior, governed by a bashaw; who has in reality but little power, but seems principally to be meant for the means of communicating to his divan of *beys*, and to the divans of the several military *agians* (that is, their bodies), the orders of the grand seignior, and to see that they be executed by the proper officers.

When Selim, sultan of the Ottomans, put a period to the duasty of the Mamlouks in 1517, he was sensible that

if he established a pacha in Egypt with the same authority which was possessed by the pachas in other provinces, the distance from the capital would be a strong temptation to revolt. For preventing this inconvenience, he projected such a form of government, that the power being distributed among the different members of the state, should preserve such an equilibrium as should keep them all dependent upon himself. The remnant of the Mamlouks who had escaped his first massacre, appeared proper for this purpose; and he next established a divan or council of regency, composed of the pacha and the chiefs of the seven military corps. The office of the pacha was, as we have observed, to notify to this council the orders of the Porte, to expedite the tribute to Constantinople, to watch over the safety of the country against foreign enemies, and to counteract the ambitious views of the different parties. On the other hand, the members of the council possessed the right of rejecting the orders of the pacha on assigning their reasons, and even of deposing him; and it was necessary that they should ratify all civil or political ordinances. It was also agreed, that the 24 governors or beys of the provinces, should be chosen from the Mamlouks. This form of government has not ill corresponded with the views of Selim, since it has subsisted about two centuries; but within the last 50 years, the porte having relaxed its vigilance, innovations have taken place, and the power of the Mamlouks has superseded and almost annihilated that of the Turks. In order to restrain the pachas, the porte had suffered the divan to extend its power, till the chiefs of the Janizaries and Azabs were left without control. Hence Ibrahim, one of the Kiayas, or veteran colonels of the Janizaries, about the year 1746, rendered himself in reality master of Egypt; and the orders of the sultan vanished before those of Ibrahim. About the year 1766, Ali Bey (see ALI BEY) rendered himself absolute master of the country. Since the revolution of Ibrahim Kiaya, and the revolt of Ali Bey, the Ottoman power has become more precarious in Egypt than in any other province; so that though the porte still retains there a pacha, this pacha, confined and watched in the castle of Cairo, is rather the prisoner of the Mamlouks than the representative of the sultan. He is deposed, exiled, or expelled at pleasure; and on the mere summons of a herald clothed in black, called "Caracoulouk," he must descend from his high station, or be deposed. Some pachas, chosen expressly for that purpose by the porte, have endeavoured by secret intrigues to recover the power formerly annexed to their title; but the beys have rendered all such attempts so dangerous, that they now submit quietly to their three years' captivity, and confine themselves to the peaceable enjoyment of their salary and emoluments.

After sultan Selim I. had taken Syria from the Mamlouks, he subjected that province, like the rest of the empire, to the government of pachas, or viceroys, as the term signifies. (See SYRIA.) In each province the pacha, being the image of the sultan, is, like him, an absolute despot. All power is united in his person; he is chief both of the military and of the finances, of the police and of the criminal justice. He has the power of life and death; he has the power of making peace and war; and in a word, he can do every thing. These powers in their unlimited extent belong only to the pacha with three tails. The power of the pacha with two tails is not so considerable, nor his department so extensive; he cannot put any one to death without a legal trial; he is, like another, chief of the armed force of his department; but when he takes the field, he is obliged to unite his standards to those of the pacha with three tails, and to march under his orders. The main object of such power vested with the pacha, is to

collect the tribute and to transmit the revenue to their master. This duty fulfilled, no other is required from him; the means employed by the agent to accomplish it is a matter of no concern: those means are left to his discretion; and such is the nature of his situation, that he cannot be delicate in his choice of them; for he can neither advance, nor even maintain himself, but in proportion as he can procure money. The place he holds depends on the favour of the visier, or some other great officer; and this can only be obtained and secured by bidding higher than his competitors. He must therefore raise money to pay the tribute, and also to indemnify himself for all he has paid, support his dignity, and make a provision in case of accidents. Accordingly, the first care of a pacha, on entering on his government, is to devise methods to procure money, and the quickest are invariably the best. The established mode of collecting the miri and the customs, is to appoint one or more principal farmers, for the current year, who, in order to facilitate the collection, divide it into lesser farms, which are again subdivided, even to the smallest villages. The pacha lets these employments to the best bidder, wishing to draw as much money from them as possible. The farmers, who, on their side, have no object in taking them but gain, strain every nerve to augment their receipt. Hence an avidity in these delegates always bordering on dishonesty; hence those extortions to which they are the more easily inclined as they are sure of being supported by authority; and hence, in the very heart of the people, a faction of men interested in multiplying impositions. The pacha may applaud himself for penetrating into the most hidden sources of private profits, by the clear-sighted rapacity of his subalterns; but what is the consequence? The people, denied the enjoyment of the fruit of their labour, restrain their industry to the supply of their necessary wants. The husbandman only sows to preserve himself from starving: the artist labours only to support his family; if he has any surplus, he carefully conceals it. Thus the arbitrary power of the sultan, transmitted to the pacha, and to all his subdelegates, by giving a free course to extortion, becomes the main spring of a tyranny which circulates through every class, whilst its effects, by a reciprocal re-action, are every where fatal to agriculture, the arts, commerce, population; in a word, to every thing which constitutes the power of the state, or, which is the same thing, the power of the sultan himself.

This power is not subject to less abuses in the army. Perpetually urged by the necessity of obtaining money, on which his safety and tranquillity depend, the pacha has retrenched, as far as possible, the usual military establishment. He diminishes the number of his troops, lessens their pay, winks at their disorders; and discipline is no more.

It sometimes happens that the pachas, who are sultans in their provinces, have personal hatreds against each other. To gratify these, they avail themselves of their power, and wage secret or open war; the ruinous consequences of which are sure to be felt by the subjects of the sultan.

It also happens that these pachas are tempted to appropriate to themselves the power of which they are the depositaries. The porte, in order to counteract their ambitious views, often changes the residence of the pachas, that they may not have time to form connections in the country; but as all the consequences of a bad form of government have a mischievous tendency, the pachas, uncertain of to-morrow, treat their provinces as mere transient possessions, and take care to make no improvement for the benefit of their successors. On the contrary, they hasten to exhaust them of the produce, and to reap in one day, if possible, the fruit

of many years. It is true, these irregularities, every now and then, are punished by the bow-string, one of the practices of the porte which best displays the spirit of his government. The ostensible reason is always for having oppressed the subjects of the sultan: but the porte, by taking possession of the wealth of the extortioner, and restoring nothing to the people, leaves sufficient room to think that the government is far from disapproving a system of robbery and plunder which it finds so profitable. Every day, therefore, affords fresh examples of oppressive and rebellious pachas; and if none of them have hitherto succeeded in forming a stable and independent government, it is less owing to these wise measures of the divan, and the vigilance of the Capidjis, than their own ignorance in the art of governing. The pachas regard nothing but money; nor has repeated experience been able to make them sensible that this, so far from being the pledge of their security, becomes the certain cause of their destruction. They are wholly devoted to amassing wealth, as if friends were to be purchased. As the pacha possesses the power of life and death, he exercises it without formality and without appeal. Wherever he meets with an offence, he orders the criminal to be seized; and the executioner, by whom he is accompanied, strangles him, or takes off his head upon the spot: nay, sometimes he himself does not disdain this office. This duty he frequently commits to a deputy, called WALLI. The administration of justice in civil suits is the only species of authority which the sultans have withheld from the executive power of the pachas. The officers appointed for this purpose are, by a wise regulation, all independent of the pachas. See CADÏ.

To the governors of provinces were formerly given indifferently the names of pacha and of beglerbeg, or beylerbey: the latter at this day is reserved for the pachas of Manastir and of Cutayé: they have the pre-eminence over the other pachas, and generally command the troops which are brought into the field. The beyler-bey of Manastir has under his orders the European troops, and the beyler-bey of Cutayé those of Asia. They are nevertheless subordinate to the grand visier, when the latter takes the general command of the armies. Formerly, the name bashaw, or pacha, was appropriated to such as had two ensigns or horse-tails carried before them; those who had the honour of three tails, called visier-bashaws, were denominated begler-begs; and those who had only one, fenchiacbegs.

The appellation of bashaw is also given by way of courtesy at Constantinople, to the lords about the grand seignor's court, the officers in the army, and almost every person of any figure.

A bashaw is made with the solemnity of carrying a flag or banner before him, accompanied with music and songs by the mirialem, an officer on purpose for the invelliture of bashaws.

Bashaw, used absolutely, denotes the prime visier; the rest of the denomination being distinguished by the addition of the province, city, or the like, which they have the command of; as the bashaw of Egypt, of Palestine, &c. The bashaws are the emperor's sponges. We find loud complaints among Christians of their avarice and extortions. As they buy their governments, every thing is venal with them. Volney's Travels into Egypt and Syria, vol. i. ch. 10. vol. ii. ch. 33. Olivier's Travels in the Ottoman Empire, ch. 17. Russell's Aleppo, vol. i. p. 135, &c.

There are also sub-bashaws, or deputy governors under the first. Phil. Trans. N° 218.

BASHAW, *Captain*, is the title of the Turkish high-admiral, who commands the naval forces of the Ottoman empire,

and is at the head of all the maritime establishments. He usually commands in person the fleets and all the naval forces of the empire; he nominates to all places and employments; he orders the building and repairing of ships; but the "Terfana-eminî" is properly the naval minister, since he has the administration of the funds appropriated to the navy, the direction of supply of stores to the arsenal, the care of the equipment of ships, and the superintendance of all the works. He has under him chiefs, deputies, and different harbour masters, as well for the execution of his orders and for private superintendance, as for the police.

BASHEE ISLANDS, in *Geography*, a group of five islands situated in the Chinese seas, north of the Philippine islands, and south of Formosa. They are said to be so called by Dampier from the name of a liquor made of the juice of the sugar cane and a small black grain, and used by the inhabitants. This name was given to the most easterly of the group, and at length was applied to them all. The productions of these islands are plantains, bananas, pine-apples, sugar-canes, potatoes, yams, and cotton; their quadrupeds are goats and hogs. The people, according to Dampier, are kind and hospitable. The names of the islands are Orange, Grafton, Monmouth, Isle of Goats, and Bashee. This group is represented in the "Missionary Voyage," p. 308. as consisting of six or seven islands; the northernmost of which lies in N. lat. 21°. E. long. 122° 6'. The two to the south-east are high; some of the others are of moderate height; the most northern except one is high and craggy at top; and between these two lie two small rocks above water. Between these islands and those of Botol Tabaco-Xima, is a channel about 16 miles wide.

BASHEE, or *Bachi*, the most easterly island of the preceding group, appearing of a circular form, and being about 2 leagues in diameter. It has a town of the same name. N. lat. 21° 45'. E. long. 122° 15'.

BASHKIRS, or *Baschkirs*, a people of the Russian empire. They call themselves Bashkourt; and derive their origin partly from the Nogay-tartars, and partly from the Bulgarians. Probably they are Nogays, whom the Bulgars adopted among them: their country at least is a part of the ancient Bulgaria. They formerly roamed about the southern Siberia under the conduct of their own princes: to avoid the molestations of the Siberian khans, they settled in their present possessions, spread themselves about the rivers Volga and Ural, and were subject to the Kazanian khanate. On the overthrow of that state by tzar Ivan II. they voluntarily took refuge under the Russian sceptre: they afterwards, however, frequently revolted against the government, whereby their prosperity as well as their population have been considerably diminished. In the year 1770, they consisted of twenty-seven thousand families, having their homeland in the governments of Ufa and Perme. The Bashkirs have been long without khans; and all their nobility have been gradually destroyed in the civil wars. At present every tribe or wolost chooses for itself one or more ancients, or starschinis; and the whole nation composes 34 wolosts. The butts or houses, which they inhabit during winter, are built after the Russian fashion; the principal part, which the family commonly possesses, is furnished with large benches, which serve for beds; the chimney, of a conical form, and of the height of an ordinary man, is in the middle of this division, and so ill constructed, that they are very liable to smoke: on this account the Bashkirs are very subject to various complaints of the eyes. In summer this people inhabit what the Russians call Jurtes; they are tents or covers of felt, which, like the huts, have several divisions and a chimney in the centre. A winter vil-
lage

lute contains from ten to fifty huts; but the summer encampment never exceeds twenty juttes. These juttes are a kind of barracks.

The Bashkirs have some knowledge of the art of writing, and have schools; but as it is from their own nation that they elect their priests and the instructors of youth, they remain in the profoundest ignorance. With some knowledge of tillage, they retain a liking to the pastoral life; which spoils them for agriculture. They sow but little grain; consequently their harvests afford them only a few resources for the winter, being far from sufficient for their whole consumption. They apply with greater success to the cultivation of bees; making hollows in the trees to serve the purposes of hives; which to secure from the attacks of the bears, they have invented a variety of ingenious contrivances both as weapons and traps. One man, in frequent instances, is known to possess at least five hundred hives. They have the art of finding out the mountains that contain mines; but, like the Tartars, they would think themselves disgraced by working them themselves. It must be owned, however, that they have not the strength of body which that labour requires. Their practice is to let them out for a term of sixty years to Russian contractors, assigning to them at the same time a tract of forest necessary for the forges. The poorest of them serve for wages in transporting the ore.

The women understand the art of weaving, fulling, and dyeing narrow coarse cloths; they likewise make the clothes for the whole family. They make a small quantity of linen of hemp; but they prefer weaving the filaments of the common nettle, as that plant requires no culture, and the linen they make of it is extremely coarse. They have not the unwholesome practice of steeping their hemp or their nettles in water, but leave them to dry in the air on the top of their huts during the autumn and winter; then stripping off the bark, they pound them in wooden mortars. The men follow the more difficult business of making felt and of tanning leather. Both sexes wear shirts of the cloth made of nettles; they also wear wide drawers, which descend to the ankle-bone, and a sort of slippers, like people in the East. Both men and women wear a long gown, that of the men being generally of red cloth bordered with fur; this they bind round their middle with a girdle, or with the belt to which they fix their scymitar. The poor have a winter pelisse of sheep skin, and the rich wear a horse skin in such a manner that the mane covers their back and waves in the wind. The cap is of cloth, like the frustum of a cone, and 10 inches high; and that of the rich is usually ornamented with valuable furs. The gown of the wives is made of fine cloth or silk, buttoned before as high as the neck, and fastened by a broad girdle, which the richer classes have made of steel. Their necks and throats are covered with a sort of shawl, on which are several rows of coins, or a string of shells.

The principal wealth of this people consists in their flocks; it is especially from their horses that they derive the necessities of life; meat, milk, vessels, garments. They have nearly as many and even rather more sheep than horses; and their horned cattle are about half as numerous: they likewise bring up some goats, and only the rich have camels. A man of the ordinary class has seldom fewer than between thirty and fifty horses, many possess five hundred, and some a thousand, two thousand, and more. Their sheep are of the broad-tailed species; they esteem the others for the fineness of their wool.

The most opulent of the Bashkirs are those who dwell to the east of the Ural, and in the province of Iset. Some of them are owners of not less than four thousand horses,

who fatten in the richest pastures: the wasps and gnats oblige them in the month of June to quit these fine meadows, and retreat to the mountains; the horses then lose their flesh and pine away; but regain their pristine vigour on coming down again to the plains in the month of July.

Though the Bashkirs experience a long and very severe winter, yet they abandon their flocks and droves to the inclemencies of the season. They have neither granaries nor barns; they only lay up a little hay, which they range in circles round the trees, reserving it for the distempered cattle. Those that are healthy pick up a little grass or moss from beneath the snow, and are often reduced to the necessity of feeding on the bark of the young elms. No farther attention is paid to the emuls, than to wrap them in some wretched coverings of felt which they sew about their body. The cattle towards the end of the winter are become lean, weak, and emaciated. Though the females are never kept apart from the males, they rarely bring forth out of season; because the exhausted state of the flocks and herds during the winter, is unfavourable to generation. Neither the Bashkirs nor the Kabruks suffer the colts and the calves to suck their dams except during the night, their practice being to milk them in the day-time for their own advantage; kumis, prepared from mare's milk, being their favourite liquor. (See Kuzniss.) They are also fond of a mixture of four milk and bread, called *chigas*. In the spring they drink the sap of the birch, which they collect by means of deep incisions in the trees.

Their arms are the bow, the lance, the helmet, and coat of mail; from the Russians they obtain sabres, musquets, and pistols. A Bashkirian army presents a truly curious spectacle; observing no order in marching, they only form into ranks when they halt. Every one leads a horse in his hand, which carries all his provisions: the load however is not heavy; consisting only of cheese, some corn dried in the kiln, and a hand-mill to grind it to meal. With the meal they form a ball which they swallow, and which serves them for bread. Each warrior, dressed in his long gown, equips himself as he chuses or as he can. One has procured for himself the various kinds of arms, and carries a whole arsenal with him; the other scarcely possesses more than one ill-conditioned weapon. Such troops as these rendered the armies of the ancient Persians at once so numerous and so little formidable.

They are all well mounted, are skilful in drawing the bow, and dexterously manage their horses. A small number of Bashkirs are easily victorious over a numerous Squadron of Kirghises; sometimes one of their regiments will traverse a whole horde of Kirghises, put to flight by their very looks all the enemies they meet, and return triumphant without having sustained the slightest loss. The military service which they are bound to perform, and the only point in which they are galled by the Russian yoke, consists in furnishing, in time of war, 3000 cavalry, which form 30 troops of 100 men each. The Bashkirians are the most negligent and slovenly of the Tartars. In commerce they are the least intelligent; but, at the same time, they are the most hospitable, the most lively, and the most brave. Their diversions at any religious festival, or at a marriage, consist in numerous libations of four milk, singing, dancing, wrestling, and horse racing, in which they excel. In their songs they enumerate the achievements of their ancestors, or their own, and sometimes their amorous adventures. Their songs are always accompanied with gestures, which render them very theatrical. Among them old age meets with the greatest respect. In their entertainments, it occupies the place of honour; and the stranger, to whom compliments are paid,

is always set among the old men. The language of these people is a Tartar dialect, very different from that spoken at Kafan. The Bahkirians are, like most of the Tartars, Mahometans; but though they have their mosques, their molaks, and their schools, they are much addicted to superstition and foreery. Their foreerers challenge even the devil, and pretend to engage with him in combat; and thus they delude the credulous vulgar, who consult them in their distress, and particularly when they lose any of their mares. Took's View of Russia, vol. i. p. 473. Chantreau's Travels, vol. i. p. 281.

BASHLI, or **BASCATI**, in *Geography*, a small town on a brook of the same name, at the distance of 4 German miles from the Caspian sea.

BASHUYSEN, **HENRY JAMES VAN**, in *Biography*, a learned divine, was born at Hanau, in Germany, in 1679, and educated at Bremen, Leyden, and Francker. In 1701, he was appointed professor of the oriental languages and ecclesiastical history in the gymnasium of Hanau, afterwards professor of theology; and in 1712, he was elected member of the Royal Society of Berlin. He was afterwards professor of theology, the oriental languages, and history, in the gymnasium at Zerbitz, where he died in 1758. About the year 1709, he established in his own house a printing-office, in which he printed many Hebrew and Rabbinical works. Among his writings are "Obierv. Sac. lib. i. de integritate Sac. Script." Frankf. 1708, 8vo; "Comment. R. if Ababun, in pentateuchum Moïsis, &c." Hanov. 1710, fol. "Disput. iii. de Kabbala vera & falsa," Hanov. 1710, 1711, 1712, 1713, 4to.; "Systema Antiq. Hebr. minus," Hanov. 1715, 8vo.; "Miscellanea Sacra, &c." Witteb. 1719, 4to.; "Diff. de Hilde, &c." Serv. 1719, 4to.; "Clavis Talmudica, &c." Hanau, 1740, 4to. Gen. Biog.

BASIA ULTIMA. See **ULTIMA**.

BASIATRAHAGI, in *Botany*, a name used by some for the common *polygonum*, or knot-grass.

BASIENTO, in *Geography*, a river of Naples, which rises near Potenza, in the province of Basilicata, traverses this province, and runs into the gulf of Tarento. This is the ancient Metapontus, or Casertum, on which Octavius Cesar and Mark Antony had an interview, brought about by the mediation of Octavia.

BASIL, **St.**, denominated the *Great*, in *Biography*, was born in Cappadocia, in the year 328 or 329. Having received instruction from his father in polite literature, he pursued his studies at Antioch under Libanius, at Casarea in Palestine, at Constantinople, and at Athens; in which latter place he formed an intimate acquaintance with Gregory Nazianzen, and was introduced to Julian, afterwards emperor. In 355, he returned to his native country, and became a professor of rhetoric, and a pleader. His religious zeal, however, soon induced him to visit the monasteries in the deserts of Egypt and Lybia; and here his imagination was so impressed with the austerities of the devout solitaries in these sequestered mansions, that he withdrew to a retired spot in the province of Pontus, and embraced the monastic life. He was soon joined by his brother and several friends, to whom he gave a set of ascetic rules; and he is regarded as the founder of all similar institutions in Pontus and Cappadocia. His monastic life continued, but not without some interruption by other avocations, for twelve years. Having been ordained priest by Eusebius bishop of Casarea, he again withdrew to his solitude; but as his fame increased, he was elected to this see on the death of Eusebius in 369, 370, or 371. Here he succeeded Athanasius in the conduct of the Trinitarian controversy. Many attempts were made by the emperor Valens, who was an Arian, partly by friendly solicitations and partly by angry menaces, to induce him to com-

municate with Eudoxus, the Arian bishop of Constantinople; but altogether without effect. Basil however, remaining firm and inflexible, was left in the free possession of his conference and his throne. The emperor himself assisted at the solemn service of the cathedral, and subscribed the donation of a valuable estate for the use of an hospital which Basil had lately founded in the neighbourhood of Casarea. The bishop employed himself with much assiduity in endeavouring to recover the eastern and western churches, which had differed on account of the two rival bishops of Antioch; and he also attempted to terminate the disputes between the two churches respecting the hypostases: but his endeavours were unavailing. He was likewise engaged in disputes more personally interesting to himself; for the emperor having divided his province of Cappadocia into two parts, Anthimus bishop of Tyana, the metropolitan of the new moiety, attempted to enlarge his limits. Basil resisted this usurpation; and, erecting the little border town of Sasima into a bishopric, with a view of securing his boundaries, he appointed his friend Gregory Nazianzen to this see. Gregory submitted with reluctance to this humiliating exile, and embraced the first opportunity that offered of withdrawing from it to the government of his native church of Nazianzus, of which his father had been bishop above 45 years. After some other theological contentions, Basil closed his life in 378, or 379, or 380, after having been bishop somewhat more than eight years. The talents and accomplishments of this prelate have been highly extolled; and, allowing for some alloy of spiritual pride, not without justice. Few of the fathers occupied a higher rank. His style is pure, elegant, and dignified; so that Erasmus makes no scruple in equalling or even preferring his eloquence to that of Demosthenes and the most celebrated orators of ancient Greece. His erudition was extensive; his reasonings more close and forcible, and his illustrations of scripture more natural than those of many of the fathers. Many writings have been ascribed to Basil without sufficient reason; and, therefore, many learned moderns, among whom we may reckon Cave, Fabricius, Tillemont, Dupin, and especially Garnier, have taken laudable pains in distinguishing the spurious from the genuine. Of the various editions of his works that have been published, the first in Greek was that of Frobenius at Basil in 1532, under the inspection of Erasmus; and the best modern edition of all his works, consisting of "Homilies, Epistles, Commentaries, and Moral Treatises," is that of the learned Benedictines, D. Garnier and D. Prudent Morand, at Paris, 3 vols. folio, from 1721 to 1730, with a Greek text: this edition contains a faithful and elegant Latin version, and valuable notes. The "Life of St. Basil" was written at large by M. Hermant, in 2 vols. 4to. 1674. Cave, H. L. vol. i. p. 238, &c. Dupin, Bib. t. ii. p. 154, &c. Dupin, Eccl. Hist. vol. i. p. 122, &c. Fabr. Bib. Græc. t. vii. p. 60, 69. Lardner's Works, vol. iv. p. 400. Gibson's Hist. vol. iv. p. 260, vol. v. p. 19.

BASIL, bishop of Ancyra, was placed in that see in 339, by the council of Constantinople which deposed Marcellus, and he himself was deposed at the council of Sardica in 347, though by the favour of the emperor he retained his see. In 351, he was present at the council of Sirmium, and had a dispute with Photinus. Epiphanius reckons him among the chief of the Semi-Arians, who held the Son to be of like substance to the Father; Sozomen says he was in esteem for eloquence and learning; and Theodoret observes, that he was in great favour with the emperor Constantine for his piety. His peculiar opinion with regard to the identity of the substance of the Father and the Son was, by his influence, established in the council of Ancyra held A. D. 358; and he maintained it in several disputes with the Eudoxians and

Acacians, in the presence of Constantius. However, the Acacians prevailed against him in the council of Constantinople, A. D. 560, and procured his deposition; nevertheless he kept possession of his see, and was acknowledged as bishop by the orthodox prelates. Basil is supposed to have died, either at the end of Jovian's reign, or the beginning of that of Valens. Cave, *Hist.* tom. i. p. 210. Lardner's Works, vol. iv. p. 125.

BASIL *Stem, and Herb*. See THYMUS.

BASIL, *Order of St.*, in *Ecclesiastical History*, is the most ancient of all the religious orders. It takes its name from St. Basil, bishop of Caesarea, in Cappadocia, about the middle of the fourth century; who is supposed to have been the author of the rules observed by this order, though some dispute it. The order of St. Basil was anciently very famous in the East, and still continues in Greece. The habit of the monks is black, and plain, consisting of a long cassock, and a great gown with large sleeves; on their head, they wear a hood, which reaches to the shoulders; they wear no linen; sleep without sheets, on straw; eat no flesh; fast often; and till the ground with their own hands. The historians of this order inform us, that it has produced 1805 bishops, and beatified, or acknowledged as saints, 3010 abbots, 11,805 martyrs, and an infinite number of confessors and virgins. They likewise place among the religious of this order of St. Basil 14 popes, several cardinals, and many patriarchs, archbishops, and bishops. It likewise boasts of several emperors and empresses, kings and queens, princes and princesses, who have embraced the rule of St. Basil.

This order was introduced in the West in 1057, and was reformed in 1579 by pope Gregory XIII. who united the religious of this order in Italy, Spain, and Sicily, into one congregation; of which the monastery of St. Saviour, at Messina, is the chief, and enjoys pre-eminence over the rest. Each community has its particular rule, besides the rule of St. Basil; which is very general, and prescribes little more than the common duties of a Christian life.

BASILE, *Basle, or Bâle*, in *Geography*, one of the new cantons of Switzerland, which joined the Helvetic confederacy in 1501. It is bounded on the south-west and south by the canton of Soleure, on the east by Lower Argow and the canton of Baden, on the north-east by the territory of Rheinfelden, one of the forest towns, and on the north-west by Alsace, and on the west by the bishopric of Basle. Its extent is about 160 square miles, and its population is estimated at 40,000 persons. The lower parts of this canton are fertile in corn and wine, and also fit for pasture; but the mountains are extremely barren. It has many medicinal springs and baths, and the air is temperate and salubrious. The religion of this canton is the reformed, or Protestant. As to its ancient government, the bishops of Basle once possessed the sovereignty over the city and canton; but when they quitted this town in 1501, and retired, first to Friburg in Brisgau, and afterwards established their residence at Porrentru, they lost the inconsiderable authority and few prerogatives that belonged to them. Upon the introduction of the reformation in 1525, the constitution was in some measure changed, and the power of the aristocracy limited. Before the late revolution, the government was aristocratic, inclining towards a democracy. The supreme legislative power resided in the great and little councils, consisting of about 300 members, and the authority of these two councils was without controul; they enacted laws, declared war and

peace, contracted alliances, and imposed taxes; they elected the several magistrates, appointed their own members, nominated to all employments, and conferred the right of burghership. The general administration of government was committed, by the great council, to the senate or little council; that is, to a part of its own body. This senate, composed of sixty members, together with the four chiefs of the republic, two burgomasters, and two great tribunes, was divided into two bodies, which acted by rotation; the acting division continued in office one year, decided finally in all criminal causes, superintended the police, and exercised several other powers subordinate to the sovereign council. The collective body of citizens assembled only once a year, when the magistrates publicly took an oath to maintain the constitution, and to preserve the liberties and immunities of the people inviolate. The reciprocal oath of obedience to the laws was administered to the citizens in their respective tribes. But, notwithstanding the boundless prerogatives of the great council, the meanest citizen was legally capable of being admitted into that body, and, by the singular method of election, might possibly be chosen; for the vacancies in the two councils were supplied from all ranks of citizens, the members of the university only excepted. These citizens were divided into eighteen tribes, fifteen of which belonged to the larger towns, and three to the smaller; each of the fifteen tribes returned four members to the senate, and each of the eighteen sent twelve to the great council. As these elections were formerly determined by a plurality of voices, the richest person was always almost certain of being chosen; to prevent which, a regulation, called a "ternaire," was established; that is, three candidates were nominated, and from these the successor was appointed by lot. In 1740, an act was passed, by which the "ternaire" was changed into a "fenaire," by which six candidates were put in nomination, and drew lots for the charge; six tickets, containing the names of the respective candidates, and separately placed in silver eggs, were put into one bag, and the same number of tickets, five being blanks, and one marked with the vacant employment, were put into another bag: the reigning burgomaster and the great tribune, appointed to be the drawers of this official lottery, both at the same instant took a ticket from each bag, and the candidate whose name came out with the ticket on which the employment was written, obtained the post.—But it is now needless to pursue the detail.—In 1798, the Helvetic confederacy was dissolved by the invading power of France, and, according to the distribution of that year, Basle was constituted one of the eighteen departments into which Switzerland was divided: but according to the constitution of 1801, Basle was made one of the departments, with the addition of the lower part of the Frickthal to Seckingen, with the right of deputing three representatives to the diet.

Basle was the first canton which separated from the old Helvetic confederacy, and adopted the new constitution fabricated in France. Its situation near the frontiers, exposed it to the intrigues of the French agents, and without foreign support, rendered it incapable of resistance. The peasants of the canton were likewise dissatisfied with the monopoly of power and commerce vested in the burghers of the town. Encouraged by the French, and excited by their own turbulent demagogues, they peremptorily required emancipation and independence. The progress of the revolution in this canton was almost instantaneous; the magistrates were incapable of resistance, and obliged to resign their authority; and sixty delegates, appointed by the people, were invested with a provisional government, until the new constitution should be consolidated. Coxe's Travels in Switzerland,

vol. i. What other changes await the Swiss cantons, time must develop. See SWISSERLAND.

BASIL, or BASLE, the capital of the canton of the same name, is the largest, and seems formerly to have been one of the most populous towns in Swisserland. Its extent is capable of containing above 100,000 inhabitants, and it is said to have 220 streets, and six market-places or squares; whereas it can now scarcely number more than 14,000. Among the causes which have contributed to its decrease, Mr. Coxe mentions the jealousy of the citizens with regard to the burgherhip, which they seldom deign to confer upon foreigners; and, on this account, no supply can be obtained to balance that gradual waste of people which takes place in great cities, from an influx of strangers, who are not permitted to carry on commerce, or to follow any trades. The late law that allows the freedom of the town and the right of burgherhip to be conferred upon strangers, is clogged with so many restrictions, that it by no means answers the purpose for which it was intended.

Basle is beautifully situated on the banks of the Rhine, near the point where the river, which is here broad, deep, and rapid, after flowing for some way from east to west, turns suddenly to the north. It consists of two towns, joined together by a long bridge; the large town lying on the side of Swisserland, and the small town on the opposite bank of the river. Its environs are very beautiful, consisting of a fine level tract of fields and meadows. It was anciently called Basilea, as we learn from Ammianus Marcellinus; and in the middle ages, Basula; and it appears in history, soon after the reign of Charlemagne; having succeeded AUGUST, or the Augusta Rauracorum. Basle is very favourably situated for commerce; and of this advantage the inhabitants have availed themselves, by establishing a great variety of manufactures, particularly of ribbands and cottons; and by the extensive trade that is carried on by the principal merchants. The cathedral is an elegant Gothic building, and contains the marble tomb of the famous Erasmus, who chose this city as his favourite place of residence, and published from hence the greatest part of his valuable works. Basle has, besides the cathedral, six parochial churches, and several other public buildings; such as a public granary and an arsenal, a town-house, and a stately palace belonging to the margrave of Baden Dourlach, a chamber of curiosities, several hospitals, &c. In the town-house is an exquisite piece of the sufferings of Christ, by Holbein, who was a native of this place; and a statue of Munatius Plancus, the Roman general, who founded Augusta Rauracorum. In the arsenal is shewn the armour in which Charles the Bald lost his life, with the furniture of his horse, and the kettle drums and trumpets of his army. On the stair-case of the council-house is a picture of the last judgment, in which, though painted before the reformation, popes, cardinals, monks, and priests, are represented in the torments of hell. Upon a wall that incloses the burial-ground of the church of the Protestants in the suburbs of St. John, is painted, in oil colours, the "dance of death," erroneously attributed to Holbein, as it was painted before he was born, in which the king of terrors is represented as mixing with all ranks and ages, and complimenting them in German verses on their arrival at the grave. From this ancient painting, it is thought, that Holbein took the first hint towards composing his famous drawings on the "dance of death." Prints were taken from some of these drawings, by Hollar, which are now very scarce. The university of Basle, founded by pope Pius II. in 1459 or 1460, was formerly eminent in the literary history of Europe. It was honoured by the celebrated names of Oecolampadius, Amerbach, the three Baulins, Grynxæus, Buxtorf,

Wetstein, Idlin, the Bernouillis, and Euler; and it still boasts of several members who are ornaments to their native town by their learning and talents. The public library contains a small collection of books, remarkable for several rare and valuable editions, particularly of those printed in the 15th century. Besides books, this library contains some valuable MSS. In a suite of rooms belonging to it, are a cabinet of petrifications, some ancient medals and gems, a few antiquities found at Augst, a large number of prints, and some fine drawings and paintings, consisting chiefly of originals by Holbein, most of which are in the highest preservation. Basle is famous for the excellence of its police, and the strictness of its sumptuary laws. Although the use of coaches is not prohibited, yet no citizen or inhabitant is allowed to have a servant behind his carriage. No person, it is said, without the city, must wear lace of gold or silver; and all young women are prohibited from wearing silks. By such regulations, a distinguishing simplicity of manners prevails even in the richest families. It was formerly a singularity belonging to this town, that all its clocks were an hour faster than the real time, which, according to some, was introduced during the council of Basle, in order to summon the cardinals and bishops in due season for the dispatch of business; others say that they were put forward, in order to defeat a conspiracy, by one of the burgomasters, who had notice of the design; by which the conspirators, thinking that they had missed the time and were too late, were induced to retire: others say, that the sundial on the cathedral, which regulates the clocks, declines somewhat from the east, and this circumstance, according to Bernouilli, occasions a variation from the true time of about 45 minutes. The inhabitants have long tenaciously maintained this ancient custom, and resisted every change; till in the late new order of things, a revolutionary change has taken place with regard to the clocks as well as the government, and they have been altered to the true time. Basle was formerly the see of a bishop; but though there is one that now bears the title, he lives at Porentru near Alface, and has no jurisdiction in this city.

The famous council of Basle began its sittings in 1431, continued its deliberations, and proceeded in enacting laws and publishing edicts, until the year 1443, notwithstanding the efforts of pope Eugenius, who had been deposed from the papacy by the council in 1429, and his adherents, to put a stop to their proceedings. And though in that year the members of the council retired to their respective places of abode, yet they declared publicly that the council was not dissolved, but would resume its deliberations at Basle, Lyons, or Lausanne, as soon as a proper opportunity occurred. Accordingly, in the year 1449, when Felix V. resigned the papal chair, the fathers of the council of Basle assembled at Lausanne, ratified his voluntary abdication, and, by a solemn decree, ordered the universal church to submit to the jurisdiction of Nicholas as their lawful pontiff. Nicholas set the seal of his approbation and authority to the acts and decrees of the council of Basle. The two grand points that were proposed to the deliberation of the famous council of Basle, were the union of the Greek and Latin churches, and the reformation of the church universal, both in its head and in its members, according to the resolution that had been taken at the council of Constance. In 1435, this council publicly abolished the "annats;" and in 1436, a confession of faith was read, which every pontiff was to subscribe on the day of his election; the number of cardinals was reduced to twenty-four; and the papal impositions called "expectatives," "reservations," and "provisions," were annulled. *Mosh. Eccl. Hist. vol. iii. p. 420, &c. N. lat. 47° 35'. E. long. 7° 20' 30".*

BASIL, or **BASLE**, *Bishopric of*, a principality of Germany, in the circle of the Upper Rhine, may be classed under two general divisions: the first lies to the south of Pierre Pertuis, and forms a part of Switzerland; the second, to the north of the same boundary, includes that district which is properly situated within the German empire. The sovereign, that is the bishop of Basle, or, as he is called by the Protestant, the prince of Porcraur, whose principal residence is Porentru, the capital of his dominions, was formerly chosen by the chapter of eighteen cantons, resident at Arelshain, and confirmed by the pope. He was a prince of the German empire, and did homage to the emperor for that part of his territory which lies in the circle of the Upper Rhine. He was always considered as an ally of the Swiss, by his union with the Catholic cantons, first formed in 1576, and renewed at different intervals, particularly in 1671 and 1697, and by being included in the treaty which those cantons contracted with France in 1715; but as he was not comprized among the allies of the Swiss, in the league between the thirteen cantons and Louis the XVth, in 1777, he was not deemed a member of the Helvetic confederacy. The first particular alliance with France was concluded in 1739, between the bishop and Louis the XVth, and was renewed in 1780. The population of that part of the bishopric of Basle that was allied to the cantons amounted to 24,000. The form of government was a limited sovereignty, the bishop being bound, on all important occasions, to consult his chapter; and his prerogative being confined, by the great immunities enjoyed by his subjects in general, and particularly by those of the reformed communion. He nominated to all employments both civil and military, and appointed the bailiffs or governors; criminal justice was administered in his name, and he had the power of pardoning. In civil proceedings, he received an appeal from the inferior courts; but in his German dominions, when the cause exceeded the value of a stipulated sum, it might be carried to the chambers of Wetzlar or Vienna. The subjects of the bishop are partly Protestants and partly Catholics: the Protestants inhabit the greater part of the valley of Munsler, and the whole district to the south of Pierre Pertuis, and are about 15,000; the Catholics amount to 35,000. The French and German languages are both spoken in the bishop's dominions. The whole bishopric of Basle is now annexed to France. In 1792, their troops overran the country of Porentru on the German part, under the pretence of delivering the natives from slavery, and took possession of the famous pass of Pierre Pertuis. This district was ceded to France by the treaty of Campo Formio, and is formed into the department of Mont Terrible. In 1798, the Helvetic part of the territory was taken possession of, in the name of the republic, by general de Cyr, under a declaration that France succeeded to the property, dominions, rights, and prerogatives of the bishop. This district was also annexed to the department of Mont Terrible. The bishopric of Basle is a fertile country, and many forges are employed in the manufactures of iron and steel.

BASIL, among *Joiners*, denotes the angle to which the edge of an iron tool is ground. To work on soft wood, they usually make their basil 12 degree; for hard wood 18; it being observed that the more acute or thin the basil is, the better and knoother it cuts; and the more obtuse, the stronger and fitter it is for service.

BASILAN, or **BASSELAN**, in *Geography*, one of the Philippines islands; 12 leagues in circumference, very fertile, especially in fruit and rice; 6 leagues S. W. of Mindanao. N. lat. 5° 51'. E. long. 121° 30'.

BASLARE Or, in *Anatomy*, a barbarous denomination

given to the *os sphenoides*, on account of its being situated at the bottom or basis of the skull; or because a great part of the brain rests upon it, as on its basis.

BASILARIS Arteria. See **ARTERY**.

BASILE, **ST.** in *Geography*, a town of Italy, in the kingdom of Naples, and province of Otranto, 18 miles east of Matera.

BASILE, **ST.** is also a town of the kingdom of Naples, in the province of Basilicata; 11 miles N. E. of Turin.

BASILEUS, *Basilis*, a title assumed by the emperors of Constantinople, exclusive of all other princes; to whom they give the title *rex, king*. The same quality was afterwards given by them to the kings of Bulgaria, and to Charlemagne; from the successors of which last they endeavoured to wrest it back again.

The title *basileus* has been since assumed by other kings, particularly the kings of England; "*Ego Edgar totius Anglie basileus confirmavi.*"

Hence also the queen of England was intitled *basilica*, and *basilissa*.

BASILEUS, in *Ornithology*, a name by which many of the old authors called the *Regulus Cristatus* of Aldrovand, the **MOTACILLA REGULUS** of the Linnæan system, or the golden-crested wren.

BASILII, in *Geography*, a river of European Turkey, which runs into the gulf of Colokitia, 4 miles N. N. E. of Colokitia.

BASILIA, **ST.** a town of European Turkey, in the Morea; 8 miles S. of Coriuth.

BASILIA, a town of Poland, in the palatinate of Volhynia; 32 miles W. S. W. of Constantinow.

BASILIA, or **BASILICO**, a fortified town north of Coriuth, situate upon the coast of the gulf of Lepanto.

BASILIANI. See **BOGOMILI**.

BASILIC, **BASILICA**, is used, in *Ecclesiastical Writers*, for a church. In which sense this name frequently occurs in St. Ambrose, St. Austin, St. Jerom, Sidonius Apollinaris, and other writers of the fourth and fifth centuries.

M. Perrault says, that basilics differed from temples, in that the columns of temples were without side, and those of basilics within.

Some will have the ancient churches to have been called basilicæ, because generally built in the fashion of the Roman halls called by that name; others, because divers churches were formed of those halls. Some have supposed that, on the conversion of Constantine, many of the ancient basilicæ were given to the church, and turned to another use, viz. for Christian assemblies to meet in; and they refer to that passage in Ausonius, where speaking to the emperor Gratian, he tells him, the basilicæ, which heretofore were wont to be filled with men of business, were now thronged with votaries praying for his safety; by which it is apprehended he must mean, that the Roman halls or courts were turned into Christian churches; and hence it has been conceived, that the name basilicæ came to be a general name for churches in after-ages. See **BASILICA**.

BASIC is chiefly applied, in modern times, to churches of royal foundation; as those of St. John de Lateran, and St. Peter of the Vatican, at Rome, founded by the emperor Constantine.

BASIC appears also to have been given, in later ages, to churches before consecration.

BASILICS were also little chapels built by the ancient Franks over the tombs of their great men; so called, as resembling the figure of the sacred basilicæ or churches.

Persons of inferior condition had only tumbæ, or porticuli, erected over them. By an article in the Salic law, he

that robbed a tumba or porticulus, was to be fined fifteen *folidi*; but he that robbed a basilica, thirty *folidi*.

BASILICA, or **BASILICUS**, in *Anatomy*, the name of a vein, arising from the axillary branch, and running the whole length of the arm. The basilica is one of the veins opened in bleeding in the arm. See **VEIN**.

BASILICA, in *Architecture*. This word, which has successively received very different acceptations, is derived from *basileus*, king, and *axis*, house: it means therefore, etymologically, royal house. Perhaps the halls of justice acquired this name in early antiquity, when the judging the people might be regarded as the peculiar regal prerogative; and it was natural that they should retain this appellation, when justice was no longer administered by kings. Among the public edifices composed of a single building, the basilica appears to have been one of the largest. It was, among the Romans, an ample hall adjoining to the Forum, in which the magistrates judged under cover; which distinguished it from the fora, where they held their sittings in the open air. Here the tribunes and centumvirs administered justice, and the juriconsulti and legati in the pay of the republic, advised those who came to consult them. Young orators declaimed in separate apartments, and the porticoes were occupied by merchants and traders. Thus these edifices were at the same time applied to the purposes of commerce and judicature.

It is to be lamented that the antique basilicas have so entirely perished, that the construction and disposition of them are involved in great doubt and obscurity. Vitruvius, the only ancient architect whose writings have descended to us, gives the following description of the Roman basilica.

“The basilica should be adjoined to the forum on the warmest side, that the merchants may confer together without being incommoded by the weather. The breadth is not made less than the third, nor more than the half of the length, unless the nature of the place opposes the proportion, and obliges the symmetry to be different. But if the basilica has too much length, chalcidicæ are made at the ends, as they are in the basilica of Julia Aquiliana. The columns of the basilica are made as high as the portico is broad. The portico is the third part of the space in the middle; the upper columns are a fourth part less than the lower. The pluteum, which is between the upper columns, should also be made a fourth part less than the same columns, that those who walk in the floor above may not be seen by the merchants below. The epistilium, zophorus, and coronæ, are proportioned to the columns, in the manner explained in the third book.”

The basilica, however, which Vitruvius erected at the colony of Julia of Fanum, did not conform to the foregoing precepts. It is thus described: “the middle *testudo* (aisle or nave) is 120 feet long, and 60 feet broad; the surrounding portico between the walls and columns is 20 feet broad. The columns, continued the whole height of the building, are 50 feet, including the capitals, and 5 feet in diameter; having behind them pilasters 20 feet high, which sustain the beams that bear the floor of the upper porticoes. Above these pilasters are others 18 feet high, which support the ceiling of the upper porticoes, which is laid lower than the roof of the *testudo*, the space between being left open in the intercolumniations for light. The columns in the breadth of the *testudo* are four, including those of the angles; and in the length, of the side next the forum, including the same angles, eight. On the other side there are but six, the two in the middle being omitted, that they may not obstruct the view of the *pronaus* of the temple of Augustus, which is situated in the middle of the side wall of the basilica.

The tribunal in this building is in the figure of a hemicycle, extending in front 46 feet, and recessing in the centre of the curvature 15 feet; so that those who attend the magistrate obstruct not the merchants in the basilica.”

From the preceding descriptions it would appear, that the ancient basilica consisted of a great nave in the middle, surrounded with only one range of porticoes; and it is thus that it has been represented in the designs of all who have restored it from the words of Vitruvius. However, the fragments of the plan of Rome taken under Septimius Severus, which still exist, shew a part of the basilica *Æmilianæ*; and in this authentic record we find two rows of columns on each side, which, supposing an exterior wall, would give two ranges of porticoes. But this valuable relic gives reason to doubt, whether the basilicas were surrounded with walls, or whether their porticoes, open on every side, communicated with the public places. The description of Vitruvius explains nothing in this particular; but it may perhaps be inferred from what he recommends relative to the warmth of the exposure, that they were not inclosed.

Supposing the entrance of the basilica to be at one end, the other was terminated by a hemicycle, in which was placed the tribunal; this circular end answers to the *abidiam* of the Christian basilica. The chalcidicæ mentioned by Vitruvius have given rise to various conjectures, which it would be useless to detail, as we have no data from which any other inference can be drawn, than that they were some kind of apartments, separated by a partition, at the ends of basilicas.

Before the excavations made at Otricoli, and the discoveries which were the result, we had only conjectures on the form and nature of the ancient basilica; uncertain vestiges were all that remained of those of Rome, and the situation of the famous basilicas, *Æmilia* and *Fulvia*, was sought in vain at Præneste. The monument of Otricoli, therefore, ought to be very precious if we find in it a true basilica, of which the reader will be enabled to judge from the following description.

To discern the essential character of a basilica, it will be useful previously to consider the difference between it and a temple. The original form of a temple is an oblong cella or body, surrounded with porticoes; and even where the lateral porticoes were suppressed, they were never deprived of a *pronaus* or portico in front. In short, in the basilica the porticoes were internal and external in the temple. Now the edifice of Otricoli has no exterior colonade, neither *pronaus* nor portico. It is a square building, surrounded with a simple wall. In the middle the entrance is by a rustic opening, without any vestige of decoration. The interior consists of a great hall, divided by porticoes into three naves or aisles. The portico immediately opposite the entrance is composed of three arches; eight Corinthian columns form the remaining three porticoes; the further end of the building is occupied by a hemicycle or tribunal, on each side of which is a small apartment. The tribunal is ascended by several steps; and round the interior of the edifice is continued a pedestal, on which were statues which have been transported to the Museum Vaticanum. The ceiling was probably of wood, as there are no remains of a vault. No vestiges lead even to suspect that in the middle there might be a base for a statue, or any thing that indicates a temple.

This monument is certainly deficient in many of the characteristics of a basilica; its plan is an exact square instead of an oblong, and the upper galleries are wanting. However, considering to what variations these edifices were subjected, according to the riches, the size of towns, and the diversities of situation; and how much Vitruvius, the author

of the precepts which should fix our ideas on this subject, has departed from his own rules in the construction of his basilica, it will perhaps be impossible not to recognize, in the edifice of Otricoli, an example of the ancient basilica.

But we cannot quit this division of the subject without mentioning a monument, interesting at any rate from the singularity of its architecture, and still more so if it preferve to us the form of the Grecian basilica. This edifice, one of the antiquities of Paestum, is in length the double of its breadth; it is formed by ranges of Doric columns, of the number of nine in each front and eighteen on each wing including the angles. On a line with the central column of each front a range of columns is continued through, dividing the building into two parts; at the foot of these columns the pavement is elevated and adorned with mosaic. These interior columns supported the roof, which was probably a terrace. The uneven number of columns in the fronts, and the narrowness of their intercolumniations compared with those of the wings, prove sufficiently that the principal entrances must have been at the sides; and this circumstance, together with the absence of any exterior wall to inclose a cella, shews that this edifice could not have been a temple. But to the purposes of a basilica it seems very well adapted; open on every side, it admitted an easy access, while the elevation or bank in the middle, would afford a tribunal suited to the simplicity of the age.

The Ecclesiastical Basilica. It is not probable that the ancient basilicas were ever converted into Christian churches; in that case, we should still be in possession of some of these monuments of antiquity. The most ancient basilicas of the Christians, those which date from the first centuries of the public exercise of our religion, were built expressly for their use; and the details of their architecture, announce but too clearly the time of their construction. But these new temples resembled so much the antique basilicas, that they retained their name; and indeed if we examine the buildings of antiquity, we shall find no other so well calculated for the purposes of our religion. These edifices, at once simple in plan and magnificent in decoration, were of a form and disposition the most advantageous that can be imagined for large halls, and their construction combined solidity with economy. Their solidity is proved by the duration of fourteen centuries of some of these buildings; and their economy consists in the lightness of the points of support, and in that of the covering which was only of carpentry. In most of the basilicas, the walls and the points of support only occupy one tenth of the total space; which, in buildings vaulted and supported with arcades, like many modern churches, take up at least twice that superficies, and require besides materials and modes of construction which quadruple the expence.

It is to Constantine, that the first Christian churches known by the name of basilicas are to be referred. This prince signalized his zeal by the erection of monuments which announced the triumph of the religion which he had embraced. He gave his own palace on the Cælian mount to construct on its site a church which is recognized for the most ancient Christian basilica. A modern building has so much masked and disfigured the ancient, that only the situation and plan of this monument can be discovered.

Soon after, he erected the basilica of St. Peter of the Vatican. This magnificent edifice was constructed about the year 324 upon the site of the circus of Nero and the temples of Apollo and Mars, which were destroyed for that purpose. It was divided internally into five aisles from east to west, which terminated at the end in another aisle from north to south, in the centre of which was a large niche or

tribunal, giving the whole the form of a cross. The largest aisle was inclosed by forty-eight columns of precious marble, and the lateral aisles had likewise forty-eight columns of smaller dimensions; two columns were placed in each wing of the terminating aisle. The whole was covered with a flat ceiling, composed of immense beams which were cased with gilt metal and Corinthian brass taken from the temples of Romulus and Jupiter Capitolinus. A hundred smaller columns ornamented the shrines and chapels. The walls were covered with paintings of religious subjects, and the tribunal was enriched with elaborate mosaics. An incredible number of lamps illuminated this temple: in the greater solemnities 2400 were reckoned, of which one enormous candelabrum contained 1360. The tombs of pontiffs, kings, cardinals, and princes, were reared against the walls or insulated in the ample porticos.

This superb temple was respected by Alaric and Totila, and remained uninjured in the various fortunes of Rome during the lapse of twelve centuries; but crumbling with age, it was at last pulled down by Julius II. and upon its site has arisen the famous basilica, the pride of modern Rome.

The third great basilica built by Constantine, that of St. Paul on the road to Ostia, still exists. The interior of this building resembles precisely that of St. Peter which has just been described. Of the forty columns inclosing the great aisle, twenty-four are supposed to have been taken from the mausoleum of Adrian; they are Corinthian, about three feet diameter, fluted their whole length, and cabled to one third: the columns are of blue and white marble, and antiquity presents nothing in this kind more precious for the materials and the workmanship. But these beautiful remains seem only to be placed there to the disgrace of the rest of the construction, which is of the age of Constantine and Theodosius, and which most strikingly exemplifies the rapid decline of the arts.

The churches we have hitherto described bear a very complete resemblance to the antique basilica in plan and proportion. The only remarkable difference is, that the superior galleries are suppressed, in the place of which a wall is raised upon the columns of the great aisle, which is pierced with windows, and supports the roof.

The church of St. Agnese out of the walls, though not one of the seven churches of Rome which retain the title, is however a perfect imitation of the antique basilica. This resemblance is so complete, that without the testimony of writers who inform us that it was built by Constantine at the request of Constantia his sister or daughter, and without the details of its architecture which forbid us to date it higher, it might be taken rather for an ancient tribunal of justice than a modern church. It forms an oblong internally, three sides of which are surrounded with columns forming the porticos; the fourth side opposite the entrance is recessed in a semicircle; this is the tribunal. The first order of columns carries a second, forming an upper gallery, above which begins the ceiling of the edifice. The shortening of the columns, recommended by Vitruvius, is observed in the upper order.

We have hitherto observed in the Christian basilicas but small variations from the antique construction: they were still simple quadrilateral halls divided into three or five aisles, the numerous columns of which supported the flat ceiling; but the cross form, the emblem of Christianity, which began to be adopted in these buildings, operated the most essential changes in their shape. The intersection of the crossing aisles produced a centre, which it was natural to enlarge and make principal in the composition; and the invention of

domes

domes supported on pendentives enabled the architects to give size and dignity to the centre, without interrupting the vista of the aisles. The church of St. Sophia at Constantinople was the first example of this form.

The seat of the Roman empire being transferred to Constantinople, it is natural to suppose that the disposition of the ancient St. Peter's of Rome, esteemed at that time the most magnificent church in the world, was imitated in that which Constantine erected for his new capital under the name of St. Sophia. This last did not exist long: Constantius the son of Constantine, raised a new one which experienced many disasters. Destroyed in part, and rebuilt under the reign of Arcadius, it was burnt under Honorius, and re-established by Theodosius the younger; but a furious sedition having arisen under Justinian, it was reduced to ashes. This emperor having appeased the tumult, and wishing to immortalize his name by the edifice he was about to erect, assembled from various parts the most famous architects. Anthemius of Tralles and Isidore of Miletus were chosen; and as they had the boldness to attempt a novel construction, they experienced many difficulties and disasters: but at last they had the glory of finishing their design.

The plan of this basilica is a square of about 250 feet. The interior forms a Greek cross, that is, a cross with equal arms; the aisles are terminated at two ends by semicircles, and at the other two by square recesses, in which are placed two ranges of tribunals. The aisles are vaulted, and the centre, where they intersect, forms a large square, upon which is raised the dome, of about 110 feet diameter. The dome, therefore, is supported upon the four arches of the nave and the pendentives or spandrels which connect the square plan of the centre with the circle of the dome.

The general effect of the interior is grand; but whatever praises the bold invention of this immense dome may merit, it must be confessed that there are times in which princes, however great and liberal, can only produce imperfect monuments, of which this edifice is a striking example. All the details of its architecture are defective and barbarous.

However, from the communication established between Greece and Italy at the revival of letters, this basilica, the last as well as the most magnificent of the lower empire, was that which influenced most the form and architecture of the new temples. The Venetians, in the tenth century, copied with success the best parts of the disposition of St. Sophia in the church of St. Mark. This is the first in Italy which was constructed with a dome supported on pendentives; and it is also this which first gave the idea, which has been imitated in St. Peter's of the Vatican, of accompanying the great dome of a church with smaller and lower domes to give it a pyramidal effect.

From this time to the erection of the basilica of St. Peter's we find the churches approach, more or less, to the form of the ancient basilica or the new construction. The church of Santa Maria del Fiore of Florence, from the magnitude of its dome and the skill which Brunelleschi displayed in its construction, acquired a celebrity which made the system of domes prevail; and this system was finally established in the noble basilica of the Vatican, which has become the type and example of later ones. The form of the antique basilica was entirely lost, and the name, which has been retained, is the only remain of their ancient resemblance.

In the pontificate of Julius II. the beginning of the sixteenth century, the basilica of St. Peter's was begun from the designs of Bramante. This great man formed the idea of suspending in the centre of the building a circular temple as large as the pantheon, or, as he expressed it, to raise the pantheon on the temple of peace; and, in fact, we find great

resemblance in size and disposition between these two edifices and the project of Bramante. He was succeeded in his office by San Gallo, who almost entirely lost sight of the original plan; but Michael Angelo, to whom at his death the undertaking was committed, concentrated the discordant parts, and contracted the whole into the form of the Greek cross. Michael Angelo died in 1564, while he was engaged in erecting the dome; but he left plans and models, which were strictly adhered to by his successors Vignola, J. della Porta, and Fontana, who terminated the dome. The building was carried on under many succeeding pontiffs; and at last, by lengthening the longitudinal nave, it acquired the form of the Latin cross; in that particular, approaching to the original design of Bramante.

The general form of this edifice externally is an oblong, with circular projections in three of the sides; the plan of the interior consists of a Latin cross, the intersection of the arms of which is enlarged and formed into an octagon; the head of the long aisles and the ends of the cross aisles are terminated in hemicycles, and the great nave is accompanied with lateral aisles and with several inclosed chapels. The octagon centre supports a circular wall enriched with pilasters and pierced with windows, above which rises the magnificent dome.

Thus we have traced the progress of the basilica from the quadrilateral hall of the ancients with its single roof and flat ceiling supported on ranges of columns, to the cross-shaped plan, central dome, and vaulted aisles supported on massy piers of the modern cathedral. It only remains to treat of the

Modern Basilica. We give this name with Palladio to the civil edifices which are found in many Italian cities, and the destination of which is entirely similar to the antique basilica.

In imitation of the ancients, says this celebrated architect, the cities of Italy construct public halls which may rightly be called basilicas as they form part of the habitation of the supreme magistrate, and in them the judges administer justice. The basilicas of our time (he continues) differ in this from the ancient; that those were level with the ground, while ours are raised upon arches in which are shops for various arts and the merchandize of the city. There the prisons are also placed, and other buildings belonging to public business. Another difference is that the modern basilicas have the porticos on the outside, while in the ancient they were only in the interior. Of these halls there is a very noble one at Padua; and another at Brescia, remarkable for its size and ornaments.

But the most celebrated is that of Vicenza; the exterior part of which was built by Palladio, and the whole so much altered that it may pass for his work. The body of the building is of much greater antiquity, though the date of it is unknown.

Time and various accidents had reduced this edifice to such a state of decay, that it was necessary to think seriously of preventing its total ruin: for this purpose the most eminent architects were consulted, and the design of Palladio was approved. He removed the ancient loggias, and substituted new porticos of a very beautiful invention. These form two galleries in height, the lower order of which is ornamented with Doric engaged columns, at very wide intervals, to answer to the internal pillars of the old building; the space between each column is occupied by an arch resting on two small columns of the same order, and a pilaster at each side against the large column, which leaves a space between it and the small columns of two diameters. The upper portico of Ionic columns is disposed in the same manner, and a balustrade is placed in the archways. The entablature

entablature of the large capital is supported over each column.

The edifice is 200 feet long, and 100 feet broad; the height of the dome is 100 feet, and is formed by vaulted supports on piers, and the roof is covered with a wooden dome. See *Zedl. II.* c. 1. 1. 1. of the Roman basilica, from the description of Vitruvius. *Zedl. III.* the basilica at Padua. *Plat. IV.* the plan of the old basilica of St. Peter, founded by Constantine. *Zedl. BASILICÆ, *BASILICÆ*, a collection of the Roman laws, translated into Greek by order of the emperor Basil and Leo, and which were of force in the eastern empire till its dissolution.

The basilics comprehend the statutes, decrees, code, and novels, and some edicts of Justinian and other emperors. The collection consisted of sixty books, for which reason it was called *ἑξαστάβιβος*. It is supposed to be chiefly the work of the emperor Leo the Philosopher, who denominated it from his father Basilus Macedon, who first began it in 867, and carried the work to forty books. It was published by Leo, with the addition of twenty books more, in 880; and thirty years after, corrected and improved by his son Constantine Porphyrogenitus. Six books of the basilica were translated into Latin in 1557, fol. by Gratianus Hervetus. Of these sixty books, there are now remaining only forty-one; an edition of which, with a Latin version, was published by Charles Amibal Fabrotus, at Paris, in 1647, in 7 tomes folio; the other nineteen are in some measure supplied by Fabrotus, from the "Synopsis Basilicorum," &c. Four other books have been since discovered, and are inserted in Girard Meerman's "Novus Thesaurus Juris Civ. et Canon." tom. v. Of the whole work, the sixty books, Jo. Leunclavius has printed at Basil, in 1575, an euloge or synopsis. On the subject of the basilics, Fabricius (*Bib. Græc.* t. xii. p. 425—514.), Heineccius (*Hist. Juris Romani*, p. 396—399.), and Giannone (*Historia Civile di Napoli*, tom. i. p. 450—458.), as historical civilians, may be usefully consulted.

BASILICATA, in *Geography*, a province of the kingdom of Naples, bounded on the north by the Capitanata and the Terra di Bari, on the east by the gulf of Tarento, on the south by Principato Citra and Calabria Citra, and on the west by Principato Ultra. Its extent is about 1,605,047 moggies, 5 moggies making 4 English acres; and the number of its inhabitants about 325,682. Its rivers are Bradano, Basiento, Salandrella, Acii, and Sinao; its lakes are Lagonagro and Olmo; its mountains are for the most part branches of the Apennines; and its principal places are Acerenza, Meli, Monte-Peloso, Tricarico, Potenza, Anglona, Venosa, and Muro; its ruined cities are Metapontum and Heraclea. This province produces corn, wine, oil, saffron, cotton, honey, and wax.

BASILICI, *βασίλικαι*, in the *Græc. Empire*, was a denomination given to the prince's mandatories, or those who carried his orders and commands.

BASILICON, or *BASILICUM*, in *Pharmacy*, is the pompous denomination formerly given to an officinal unguent or plaster, much resembling and superseded by the *UNGUENTUM R. s. s. Flavæ*.

BASILICUS, or *BASILICA*, in *Astronomy*, is the name of a fixed star of the first magnitude in the constellation Leo; called also *regulus*, and *cor leonis*.

BASILICUS Sinus, in *Ancient Geography*, the gulf of Meliasso, a gulf of Asia Minor, in Caria, which it separates from Ionia.

BASILIDÆ, a people of Scythia, according to Pliny. Herodotus says, that their habitation was below the cataacts of Boryllhenes.

BASILIDES, in *Biography*, an heresiarch of Alexandria in Egypt, who flourished in the former part of the second century. Bagnage refers him to the year 121, Mill to 123, and Cave to the year 112. Grabe says, that he began to spread his notions in the time of Trajan, but chiefly under Adrian; and that he probably did not die before the beginning of the reign of Antoninus Pius; and this opinion is confirmed by Clement of Alexandria, who informs us, that he or his followers boasted of his having been taught by Glaucias, a disciple of St. Peter. Basilides has generally obtained the first place among the Egyptian Gnostics. He was the author of several works, of which the principal was his "Twenty-four Books of Commentaries," supposed by Beaufobre, Fabricius, and Jones, to be the "Gospel of Basilides," mentioned by Origen, and after him by Ambrose and Jerome. As none of his works are extant, we derive our knowledge of them from those who have detailed and exposted his errors; among whom are Irenæus, Tertullian, Clemens Alexandrinus, Origen, Epiphanius, &c. Basilides acknowledged the existence of one supreme God, self-existent, and perfect in wisdom and goodness, who produced from his own substance seven beings, or æons, of a most excellent nature. From two of these, called Dynamis and Sophia, i. e. power and wisdom, proceeded angels of the highest order, who formed a heaven for their habitation; and these angels again produced other inferior angelic beings; these were succeeded by other generations of angels, and new heavens were also created, until the number of angelic orders, and of their respective heavens, amounted, as Irenæus has suggested, and others have believed, to 365, the number of days in the Egyptian year. Beaufobre disputes this account; and it is suggested, that Basilides might possibly say, there were 365 angels, who presided each over one day of the year; which is a notion that seems to have been entertained by some persons in the east. Basilides ascribed the formation of this lower world to angels; conceiving it to be unworthy of the Supreme Being to give form and beauty to matter, and to be the author of the many evils that are in this world. These angels, perceiving matter, which was eternal, agitated in a tumultuous manner, determined to reduce it to order; and having in their minds an idea of the world of spirits to which they belonged, and which served for them as a model, proposed to form a material world that should resemble it, and to create a race of beings to inhabit it. This design was executed, and approved by the Supreme Being; who added a reasonable soul to the animal life with which alone the inhabitants of this new world were at first endowed, and who gave to the angels the empire over them. These angelic beings became gradually depraved by the influence of malignant matter, and endeavoured to efface from the minds of men the knowledge of the Supreme Being, and to arrogate to themselves the worship that was his due. The most arrogant and turbulent of these fallen angels presided over the Jewish nation. At length the Supreme Deity, observing and compassionating the ruined and wretched state of the world, sent from heaven his first-begotten Nus, or Christ, the chief of the æons, to restore the knowledge of the Supreme God, and to destroy the empire of those angels that presided over the world, and particularly that of the arrogant leader of the Jewish nation. The god of the Jews, alarmed at this, sent forth his ministers to seize the man Jesus, and put him to death. They executed his commands; but their cruelty could not extend to Christ, the heavenly being, against whom their efforts were vain. According to

Irenæus's account, Jesus appeared as man, but was not so in reality, and wrought many miracles: however he was not crucified; the Jews having, through mistake, crucified Simon the Cyrenian in his stead. Many of the ancients have, upon the authority of Irenæus, accused Basilides of denying the reality of Christ's body, and of maintaining that Simon was crucified in his stead. But this accusation, as far as it refers to Basilides himself, is groundless; for he seems to have considered the divine Saviour, as compounded of the man Jesus, and Christ the Son of God. To this purpose Beaufobre says, that, though Basilides did not believe the incarnation, or hypostatic union of the Son of God with flesh, yet he never denied that Jesus was a real person, in whom the Understanding, or Son of God, displayed his power, whom he filled with his gifts and illuminations, and invested with extraordinary influence. With regard to the ridiculous story of Simon transformed into Jesus, and crucified in his stead, he represents it as a fable which Irenæus derived from some unknown source. As Basilides believed the death of Jesus, who was a real and most excellent man, in whom the first-begotten of the Father chose to dwell, though not of the Son of God, he probably believed his resurrection; that is, that his soul ascended to heaven, and the body was left to lie in the grave, or was dissipated into the air, and among the elements of which it was composed. As the ancient Catholic writers do not particularly say that Basilides denied the resurrection of Jesus, though they assure us he and his followers denied the resurrection of the body; it is not unlikely that he admitted the resurrection, or the advancement and glorification of the soul of Jesus. Basilides believed the fact of the baptism of Jesus; and his followers, as Clement informs us, celebrated the day of his baptism as a festival, which was the 15th day of the Egyptian month Tubi, corresponding to the 9th or 10th of our January, in the 15th year of Tiberius; and they spent the whole preceding night in reading, and probably in prayers. Some persons have supposed that Basilides denied the necessity or reasonableness of our suffering martyrdom for Jesus; and yet it appears from the testimony of Clement, that he esteemed martyrdom an honourable suffering, though it is the punishment of sins committed either in this life, or in a pre-existent state. Basilides taught, that the soul only would be saved; but that the body is in its nature corruptible, and incapable of immortality. As for the spirits of the disobedient, it is said to have been his opinion, or that of his followers, that they would pass successively into other bodies. Basilides has been falsely accused of believing that actions are indifferent in their own nature, and of allowing and encouraging the practice of wickedness. On the contrary, he is represented by those whose testimonies are most credible, as strongly recommending the practice of virtue and piety, and condemning not only the actual commission of iniquity, but even every inward propensity of the mind to a vicious conduct. However, some of his practical opinions gave offence to the orthodox Christians; for he allowed men to conceal their religion, and even to deny Christ, when their lives were in danger, and to partake of the feasts of the Gentiles that were instituted in consequence of the sacrifices offered to idols: not to add, that the irregular lives of some of his disciples seemed to justify the unfavourable opinion that was entertained concerning their master. The Basilidians have been also accused of magical practices: but Tertullian says nothing of this kind; and the passage of Irenæus upon which this charge is founded, is supposed to have been corrupted. Besides, the ancient fathers perpetually confound astrology and magic; and hence Lardner is induced to be very doubtful about the truth of

this accusation. Irenæus says, that the Basilidians called the prince of the heavens Abraxas, that name having in it the number 365; and the gems, or figures, bearing this name are supposed to have originated from Basilides. However, many of these Egyptian talismans appear to have an earlier date; and the magic of this sect was probably no more than the practice of certain superstitious, rather of a foolish than of a malignant nature. See ABRAXAS.

Basilides had many followers, and his sect survived to the fifth century. Beaufobre, and after him Lardner, have given a learned and candid examination of his doctrine, in all its particulars. See Beaufob. Hist. du Manichéisme, t. II. Lardner's Works, vol. ix. p. 272—307. Meilhem, Eccl. Hist. vol. i. p. 223, &c.

BASILIDIANS, the followers of Basilides, of whom an account has been given in the preceding article.

BASILINEA, in *Entomology*, a species of PHALÆNA that inhabits Austria. The wings are greyish-brown undulated, with a little black line at the base; crest of the thorax black. Fabricius.

BASILINOPOLIS, or BASINOPOLIS, in *Ancient Geography*, an episcopal town of Asia Minor, in Bithynia.

BASILIPOTAMO, in *Geography*, the ancient Eurotas, a river of the Morea in European Turkey, which falls into the gulf Calochina.

BASILIPPUM, in *Ancient Geography*, a town of Bætica in Spain, about 20 miles from Hæpalis or Seville; now Cantillana, a citadel of Andalusia, on the Guadalquivir.

BASILIS, a town of Peloponnesus, in Arcadia, founded, according to Pausanias, by Cypselus, and situated near the Alpheus. In his time it was in ruins, among which was a temple of the Eleusinian Ceres.

BASILISCUS, in *Ornithology*, one of the synonymous names of the golden-crowned wren, among old writers. This name is a diminutive of the word *basileus*, king; and was given it on account of its golden crown.

BASILISCUS, in *Zoology*, a species of LACERTA, which, according to Linneus, has the tail long and round; dorsal fin radiated; and back of the head crested. This is the basilisk of modern naturalists, and seems to unite the two genera of Lacerta and Draco. The remarks of Dr. Shaw (in the Gen. Zool.) on this extraordinary creature are highly interesting, and ought not to escape attention. It is, according to this writer, particularly distinguished by a long and broad wing-like process or expansion continued along the whole length of the back, and to a very considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of fishes, and still more so those in the wings of the draco volans, or flying lizard. This process is of different elevation in different parts, so as to appear strongly sinuated and indented, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput, or hind part of the head, is elevated into a very conspicuous pointed hood, or hollow crest.

Notwithstanding its formidable appearance, adds this author, the basilisk is a perfectly harmless animal; and, like many others of the lizard tribe, resides principally among trees, where it feeds on insects, &c. It has long ago been admirably figured in the work of Seba; and as it is an extremely rare species, has sometimes been considered, from the strangeness of its form, as a fictitious representation. There is, however, in the British Museum, a very fine specimen, well preserved in spirits, and which fully confirms the excellency of Seba's figure; from which, in all probability, Linneus himself (who never saw the animal) took his specific description. The colour of the basilisk is a pale cinereous

ereous brown, with some darker variegations towards the upper part of the body. Its length is about a foot and half. The young or small specimens have but a slight appearance either of the dorsal or caudal process, or of the pointed occipital crest. The basilisk is principally found in South America, and sometimes considerably exceeds the length before mentioned, measuring three feet, or even more, from the nose to the extremity of the tail. It is said to be an animal of great agility, and is capable of swimming occasionally with perfect ease, as well as of springing from tree to tree by the help of its dorsal crest, which it expands in order to support its flight.

Among the French naturalists, the Iguane is a distinct genus of the oviparous quadrupeds, in which the Linnæan *lacerta basiliscus* is included under the name of basilisk.

The basilisk of the ancients existed only in the glowing fancy of their poets: they feigned it to be the most malignant of all poisonous serpents; as a creature whose breath empoisoned the very air, and whose baneful glance would alone prove fatal to all other animals. A creature gifted with such extraordinary powers could have no common origin, and therefore it was asserted to be the produce of the egg of a cock brooded upon by a serpent. Galen says its colour is yellowish, and that it has three little elevations on its head, speckled with whitish spots, that have somewhat the appearance of a crown. Aelian, Matthioli, Pliny, Lucan, and others of the most distinguished ancients, relate many marvellous properties of this creature; but, notwithstanding their authority, the basilisk, as they represent it, is most unquestionably fabulous. It is needless to add to this article any of the fables of Jerome Lobo, although Dr. Johnson has received some of them with an unwarrantable degree of credulity. The learned Prosper Alpinus informs us, on the authority of some relations, which he seems to have credited, that near the lakes contiguous to the sources of the Nile, there is a number of basilisks, about a palm in length, and the thickness of a middle finger; that they have two large scales which they use as wings, and crests and combs upon their heads, from which they are called basilisci or reguli, that is, crowned, crested, or kingly serpents. And he says, that no person can approach these lakes without being destroyed by these crested snakes. Our traveller, Mr. Bruce, observes, that having examined the lake Gooderoo, those of Count Ochia and Tzana, the only lakes near the sources of the Nile, he never saw one serpent there, crowned or uncrowned; and that he never heard of any: and, therefore, he believes this account as fabulous as that of the Acontia and other animals mentioned by Prosper Alpinus, lib. iv. cap. 4. The basilisk is a species of serpent frequently mentioned in scripture, though never described farther than that it cannot be charmed so as to do no hurt, nor trained so as to delight in music; which all travellers who have been in Egypt allow is very possible, and frequently seen. (Jerem. viii. 17. Psalm ix. 13.) However, it is the Greek text that calls this serpent basilisk; the Hebrew generally calls it tsepha, which is a species of serpents real and known. Our English translation very improperly renders it cockatrice, a fabulous animal that never did exist. The basilisk of scripture seems to have been a snake, not a viper; as its eggs are mentioned (Isaiah, ix. 5.): whereas it is known to be the characteristic of the viper to bring forth living young. Bruce's Travels in Abyssinia, vol. v. p. 201.

BASILISK is also mystically used by the alchemists, to denote the sublimate mercury of the philosophers.

BASILISK, or BASILISC, in *Artillery*, also denotes a great piece of ordnance; thus denominated from its resemblance

to the supposed serpent of that name. The basilisk throws an iron ball of two hundred pounds weight. It was much talked of in the time of Solyman emperor of the Turks, in the wars in Hungary; but seems now out of use. Maffei speaks of basilisks made of brass, which were drawn each by a hundred yoke of oxen. Modern writers also give the name basilisk to a much smaller and sizeable piece of ordnance, which the Dutch make fifteen feet long, and the French only ten. It carries forty-eight pounds.

BASILIVM FLUMEN, in *Ancient Geography*, a river of Asia, which, according to Strabo, flowed between the Euphrates and Tigris; but Ammianus Marcellinus says that it was a branch of the Euphrates, directed towards Ctesiphon, and designed for conveying water into the interior part of Babylonia. The emperors Trajan and Severus opened this canal after it had been filled up, and formed by it a communication between the Tigris and Euphrates.

BASILIVS, in *Biography*, a physician and monk of Bulgaria, in the 12th century, was the founder of the sect called Bogomili. After teaching his doctrine many years in secrecy, he was seduced to Constantinople by the emperor Alexius Comnenus, who, under pretence of learning his doctrines at a private audience, placed a secretary behind a curtain, who penned down what Basilivus delivered. The emperor afterwards convoked a council, which, on the refusal of Basilivus to retract, committed him to the flames in 1118. See BOGOMILI.

BASILUZZO, in *Geography*, one of the Lipari islands in the Mediterranean, about two miles in circumference, and raised some poles above the surface of the sea. On the south side is a narrow bay; and on the summit is a plain of no great extent, and the only part capable of cultivation, though it produces only a little corn and pulse. This scanty vegetation is nourished by a thin crust of decomposed lava, under which is soon discovered the solid lava, which, in many situations, is granitous, the quartz, felspar, and mica, being very apparent in it. Two little cottages, which belong to the proprietors of this ungrateful soil, are the only buildings, near which are some ancient ruins. Rabbits are the only animals found in this island; and as they were very mischievous to the corn, the inhabitants introduced cats, which followed them into their subterranean holes. This island, as well as those that are in its vicinity, have been produced by volcanic fires. Spallanzani's Travels in the Two Sicilies, vol. ii. p. 142, &c.

BASIN OF MINAS, a body of water of considerable extent and irregular form, situate in Nova Scotia, at the east end of the bay of Fundy, and connecting with its north-east branch by a short and narrow strait. The country on its banks is generally a rich soil, and is watered by many small rivers. The spring-tides rise here 40 feet.

BASINET, BACINET, or BASNET, in *Ancient Armour*, a species of light helmet, much used, both here and abroad, in the thirteenth and fourteenth centuries. Its name was undoubtedly taken from its form, and means a little basin. The helmet of Don Quixote gives the reader an exact idea of it. In the manuscript illuminations of the times it frequently occurs; but as it materially differed from the state helmet, it is rarely, if ever, found upon sepulchral monuments. Fauchet (*Œuvres*, f. 524. edit. 1610.) cites Froissart (vol. iii. e. exix.), to prove that it had a vizor like the helmet; and observes, that the French warriors of that æra thought the best lances came from Bourdeaux, and the best helmets and basinets from Paris, where, in his time, a "Rue de la Heaumerie" existed. The basinet is particularly mentioned in the statutes of Robert king of Scotland; and its frequent use in England may be judged of from an inscription,

22 Edw. III., whence Laurence de Haslings, earl of Pembroke, appears to have held the manor of Aston Cantloue, in capite, by the singular tenure of finding, in every war with Wales, for forty days, a foot-soldier, armed with a bow without a string, and a basinet (cum uno basineto sine cappa). See COWEL.

BASINGSTOKE, or **BASINGE**, **JOHN**, in *Biography*, a man of distinguished learning in the thirteenth century, was born at Basingstoke in Hampshire, and educated partly in the university of Oxford, and partly in that of Paris. From Paris he travelled to Athens; and on his return to England brought with him a great number of Greek MSS., and introduced the use of the Greek numeral figures into this kingdom. He was eminently instrumental in promoting the study of the Greek language; and with this view he translated from the Greek, into Latin, a grammar, which he intitled "The Donatus of the Greeks." His other works were "A Latin translation of the Harmony of the Gospels;" a volume of Sermons; and "A Latin Commentary upon Lombard's Sentences." He was preferred first to the archdeaconry of London, and afterwards to that of Leicester; and died in 1252. Gen. Diet.

BASINGSTOKE, in *Geography*, a large populous town of Hampshire, in England, 16 miles N.E. of Winchester, and 46 W. from London, whence it is a great thoroughfare to the western counties. It appears that this place was of inferior consideration to Basing, in its neighbourhood, previous to the conquest; the latter place being the head of the barony of Ports. In 1233, Peter de Rupibus, bishop of Winchester, was possessed of the advowson of both the churches, and gave the presentations to the priory of Selborne in Hampshire. These afterwards were given, among other estates, by bishop Wainfleet to Magdalen college, Oxford, in which the patronage is now vested. In the church lies buried the mother of Walter de Merton, bishop of Rochester, founder of Merton college. Basingstoke gave birth to John de Basingstoke, a learned Grecian scholar, in 1252, and the intimate friend of Matthew Paris, and bishop Groshead. Henry III., at the desire of bishop Merton, founded an hospital at this place for aged priests from his college at Oxford: of this collegiate chapel, which was endowed in 1261, there are now no remains. A beautiful ruin overlooks the town on the north side, called Holy Ghost chapel. This was founded by sir William, afterwards lord, Sandes, who, with bishop Fox, obtained a licence from Henry VIII. to found a brotherhood, to continue in perpetual succession, for the maintenance of a priest to perform divine service, and for the instruction of youth in literature. The town is a corporation, governed by a mayor, high-steward, recorder, &c. Its trade consists in the manufacture of druggets and shalloons; and the market, held on Wednesday, is very considerable for corn; the trade of the town also is much benefited by a navigable canal. Basing-house, in this neighbourhood, is rendered famous by the bold stand its possessor, Powlet marquis of Winchester, made against the parliament forces, during the civil wars in the reign of Charles I. Population; houses 512, inhabited by 2589 persons.

BASINGSTOKE Canal. This was the first channel of communications with the Thames by means of canal navigation; and in 1777, an act was obtained for uniting the waters of the river Lodden at a place called Newman springs, near the village of Basing, to the river Wey, near Weybridge in Surrey, where it falls into the Thames. One important object of this canal is the carriage of ship-timber from the woods in Hampshire, to the public and private dockyards on the Thames. The length of the course of

Basingstoke canal is nearly 44 miles. Warner's History of Hampshire, 4to.

BASIOGLOSSUS MUSCLE, in *Anatomy*, the front part of the **HYOGLOSSUS**; which see.

BASJOURA, in *Geography*. See **BAGIURA**.

BASIRE, or **BASIER**, **ISAAC**, in *Biography*, a learned and active divine in the seventeenth century, was born in 1607, according to Wood (Athen. Oxon.), in the Isle of Jersey, but according to others in France, and after an education in some school or university, not ascertained, he became master of the free-school at Guernsey. At length he obtained some preferments in England, the last of which was the archdeaconry of Northumberland, with the annexed rectory of Howick; and in 1640, he received the degree of doctor in divinity at Cambridge by mandate. In the beginning of the civil wars, he was plundered and compelled to fly; upon which he repaired to king Charles at Oxford; and in 1641, a licence was granted to him, under the public seal of the university, to preach the word of God throughout England. Upon the surrender of Oxford to the British parliament, he determined to leave the kingdom, and to propagate the doctrine of the English church among the Greeks, Arabians, &c. Accordingly he first went to Zante, an island near the Morea; and there imparted to the Greek inhabitants the doctrine of the established church, in a vulgar Greek translation of our church catechism. From hence he was compelled by the Latins to retreat to the Morea, where, at the desire of the metropolitan of Achaja, he preached twice in Greek, at a meeting of some of the bishops and clergy. He afterwards embarked for Syria, and during his abode at Aleppo, furnished the patriarch of Antiochia with an Arabic translation of our church catechism. From Aleppo he travelled, in 1652, to Jerusalem, and through the whole of Palestine. At Jerusalem he was honoured by the Greek patriarch with his lull, or patriarchal seal, and he received many tokens of respect from the Latins. At his departure from Jerusalem, the pope's vicar gave him his diploma in parchment, under his own hand and seal, in which he was styled "a priest of the church of England, and doctor of divinity." On his return to Aleppo, he passed over the Euphrates into Mesopotamia, intending to convey the church catechism in Turkish to some of their bishops, who were mostly Armenians. In 1653, after wintering at Aleppo, he travelled by land to Constantinople, where the French Protestants desired him to be their minister, promising to secure to him a competent stipend. Before he quitted the eastern parts, it was his intention to have passed into Egypt, to visit the Coptic churches, to confer with the patriarch of Alexandria, and to impart to them a competent knowledge of the doctrines and forms of the church of England. But it is not known whether he accomplished this design. In Transylvania, whither he next removed, he was honoured by Ragotzi II., prince of that country, with the divinity-chair in his new-founded university of Alba Julia or Weissenburg, and endowed with a very ample salary. During his travels, he collated the several confessions of faith of the different sects of Christians, Greeks, Armenians, Jacobites, Maronites, &c. which he kept by him in their own languages; and it was his constant endeavour, as long as he remained in the East, to persuade the several sects of Christians to introduce a canonical reformation of some errors, and to unite with the church of England. But it is said, that his good intentions for this purpose were defeated by the artifices of the court of France. Upon the restoration of king Charles II., Dr. Basire was recalled by his majesty to England, and restored to his preferments and dignities. Having quietly enjoyed his ample revenues for several years after the restoration,

he died in 1676, in the 69th year of his age, and was buried in the yard belonging to the cathedral of Durham. He appears to have been learned, active, and industrious, zealously attached to the church of England, and eminently distinguished by his loyalty. His publications were not very numerous: the principal of them were his "Deo et Ecclesie Sacrum," or sacrilege arraigned and condemned by St. Paul, Oxford, 1646, 4to. and London, 1668, 8vo; "The History of the English and Scotch Presbytery," Lond. 1659, 1660, 8vo; "The dead man's real speech," a funeral sermon for Dr. Cofin bishop of Durham, to which is annexed his life; Lond. 1673, 8vo; and his "Diatriba de antiqua Ecclesie Britannicæ Libertate," printed at Bruges by a royal exile in 1656, 8vo, and translated into English under the title of "The ancient Liberty of the Britannic Church, &c." Annexed to it is "A Letter, written by Dr. Balfre to the Hon. sir Richard Brown, resident at Paris for his majesty of Great Britain; relating his travels and endeavours to propagate the knowledge of the doctrine and discipline established in the Britannic church, among the Greeks, Arabians, &c.; dated from Pera, near Constantinople, 20th Jul. 1653." Of this letter sir R. Brown observes, "that he could never read it but as a kind of nine-and-twentieth of the A&S." This book was printed at London in 1661, small 8vo. Biog. Brit.

BASIS, in the *Ancient Music and Poetry*, denotes the equability of sounds proceeding in the same tenor. In which sense, basis stands contradistinguished from *arsis*, or elevation, as well as from *thesis*, or depression.

BASIS, in *Architecture and Chemistry*. See **BASE**.

BASIS, in *Oratory*, denotes the fourth member of a complete exordium, being that which succeeds the *apodosis*, and prepares the way for the proposition.

BASKERVILLE, SIR SIMON, in *Biography*, son of Thomas Baskerville, an apothecary at Exeter, was, at the age of eighteen years, sent to Exeter college, Oxford, where he soon distinguished himself by his superior ability and industry, which procured him a fellowship in the college before he had taken his degree of bachelor in arts. In 1606, he was chosen senior proctor in the university. He now applied himself solely to the study of anatomy and physic; and in 1611, was admitted to the degree of bachelor, and doctor in medicine, at the same time. Having acquired considerable reputation for his skill in his profession, he removed to London, and was chosen fellow, and some years after, president of the college of physicians there. He had also the honour of being appointed physician to king James, and afterwards to king Charles the First, by whom he was knighted. As his practice extended with his fame, he acquired so much wealth as to be called the rich Sir Simon; which will not be wondered at, if it be true, as was reported of him, that he had 100 patients on his list at a time. He died July 5th 1641, aged sixty-eight years, and was buried in the cathedral of St. Paul's. It does not appear that he left any manuscripts for publication, or any offspring to inherit the wealth he had accumulated. Wood's *Athenæ Oxon.* Biograph. Dict.

BASKERVILLE, JOHN, an ingenious artist, entitled to commemoration on account of his improvements in printing and type-founding, was born at Woverley in Worcestershire, in the year 1706, and inherited a small estate. Having acquired in early life a skill and taste for fine writing and cutting in stone, he removed to Birmingham at the age of twenty, where he settled as a writing-master; but he soon directed his attention to the art of jappanning, which he followed with singular ingenuity and success as long as he lived. In 1750 he turned his thoughts to letter-founding, which he pursued with great labour and expence. An edition of Vir-

gil in royal 4to. in 1756, was his first great performance; which has since fetched thrice its original price. He afterwards printed many of the Latin classics, and several English ones, in 4to. and smaller sizes. The paper and ink, as well as the type, were prepared by himself; and the beauty of his workmanship was unrivalled. The type was distinguished by a peculiar fineness and sharpness, which gave the printing a strong resemblance to fine print-hand writing; and the paper had a remarkable gloss, which set off the type, but not without offending the eye. It is observed, however, that Baskerville's editions are not remarkable for their correctness. Deriving little encouragement from bookfellers, he set up a type-foundry for sale, which business was for some time carried on by his widow, after his death in 1775. After many ineffectual attempts for the disposal of his types and matrices, they were suffered, not much to the credit of this country, to be removed to Paris, where they were purchased by a literary society for 3700*l.* and employed in a splendid edition of Voltaire's works. Mr. Baskerville was distinguished by the elegance of his taste in his house, and every thing that belonged to him. The pannels of his carriage were elegant pictures, and he was drawn by a beautiful pair of cream-coloured horses. He seems to have been inclined to ostentation and singularity: however, he was polite and hospitable to strangers, and ambitious of cultivating acquaintance with ingenious men. He was not connected with any religious sect, and was buried under a mausoleum in his own grounds. Biog. Brit. Gen. Biog.

BASKET, a kind of vessel made of osier, wicker, rushes, or the like, of different figures and sizes, according to the purpose which it is intended to serve.

Baskets have their uses not only in the œconomical, but military affairs; at sieges, they make use of a small basket filled with earth and ranged on the top of the parapet.

They are about a foot and a half high, as much in diameter at top, and eight or ten inches at bottom; so that being set together, they leave a sort of embrasures at the bottom, through which the soldiers fire, without exposing themselves.

BASKER also imports a kind of measure or quantity of certain commodities.

BASKET, *corbelle*, in *Architecture*, a kind of vase, or figured piece of sculpture, in form of a basket, filled with flowers or fruits, serving to terminate some decoration.

BASKET-fish, in *Natural History*, a name given by the English in North America to a very remarkable fish, sometimes caught in the seas thereabout, though not frequently any where.

Mr. Hooke, to whom it was referred by the Royal Society to name it, has called it *Pycis echinostellaris visiformis*, the body of it resembling an egg-fish, or *echinus marinus*, and the arms a star-fish, and finally, the dividing of the branches being more like that of the branches of mistletoe than any other natural production we are acquainted with.

This fish spreads itself from a pentagonal mouth-piece, or root, in the centre of which the mouth is placed, into five main limbs or branches; and each of these, at its first issuing out of the body, is divided into two: this makes ten. Each of these ten again divides into two, which makes twenty, and so on, each dividing to the fourteenth time; at which place they make more than fourscore thousand limbs. These are too small to be traced farther by the eye, or preserved in carriage: but it is very probable that even these were again divided, perhaps several times.

The branches between the joints are not all equally of a length, though, for the most part, they are pretty nearly so. The arms or branches are never very strong; but when they

are dry, they are much more brittle than before; the least force imaginable destroying them.

The shoals of Nantucket, an island on the coast of New-England, at times furnish the fishermen with this creature; but it is remarkable, that they are never seen there unless when taken by hooks in fishing for other fish. They clasp the hook-bait fast, and encircle it with all their arms, coming up, when drawn by it, in form of a wicker basket; whence the name: but when they have been some time out of the water, they become flat.

The use of the numerous arms of this fish is plainly to catch its prey. It probably extends them to their full length while under the water, and then clasps hold of any thing fit for food that chances to swim over them. The fishermen have sometimes found the arms containing small mackerel, or pieces of larger. Phil. Trans. N^o 57 and 74. It is evident from the description, that this fish is of the *stellata arborescens*, or branched star-fish kind; but whether the same with the commonly known kind, called the *caput medusa*, is not evident from this description. The body of this fish, by what is related of its protuberance, and resemblance to the *echini marini*, may probably be the *asteropodium* in its fossil state. See ASTERIAS, and ASTEROPEDIUM.

BASKET salt. This is brine salt, made from the water of our salt springs in Cheshire, and elsewhere, differing from the common brine salt in the fineness of the grain, and in its whiteness and purity.

In the preparing of this kind of salt, some use resin, and other additions, to break the grain and make it small; others effect this by keeping up a very brisk fire under it, and stirring it all the while: but the most approved method is only to take out of this kind the third draught of every pan that is working for the common brine salt, and to do this before the granules or crystals are perfectly formed. By this means the salt is very fine: and when it has been hard pressed down into small wicker baskets, it is dried at the stove in them, and so kept for sale.

BASKING-SHARK, in *Ichthyology*, the English name of *SQUALUS MAXIMUS*.

BASKINRIDGE, in *Geography*, a town of America, in Somerset county, New Jersey, on the W. side of a N. W. branch of Passaic river, nearly 6 miles N. E. from Pluckemin, and 7 S. S. W. from Morristown.

BASNAGE, BENJAMIN, in *Biography*, son of a French minister, first settled at Norwich, in England, and afterwards at Charenton, in Normandy, was born in 1580; and devoting himself to his father's profession, succeeded him at Charenton, where he spent the remainder of his life. In 1623 he assisted at the synod of Charenton, as deputy from the province of Normandy; and he was chosen, on account of his distinguished talents and prudence, moderator of the national synod of Alençon, in 1637. He was afterwards associated to the moderator of the synod of Charenton in 1644, and being deputed by this synod to the queen-mother, received from her tokens of esteem. He was also deputed by the protestant churches in France, to king James VI. of Scotland; and being allowed to visit that country, he was eminently useful in serving the interests of his constituents. Basnage had several disputes with the Catholics, and wrote "a Treatise on the church" which was much esteemed. He also left an imperfect "Work against the indiscreet worshippers of the blessed virgin." He died in 1653, in the fifty-ninth year of his minority, and left two sons of distinguished merit. Gen. Dict.

BASNAGE, ANTONY, eldest son of the former, was born in 1610, and became minister of Bayeux. He distinguished himself by his firmness and resolution during the persecution of the protestants; and after having been imprisoned at Havre-

de-Grace, at the age of 75 years, he was released by the revocation of the edict of Nantes, and fled to Holland. He died at Zutphen in 1691. Gen. Dict.

BASNAGE, HENRY, younger son of Benjamin, was born at Sainte Mere Eglise, in Lower Normandy, in 1615. Educated to the profession of the law, he became one of the most learned and eloquent advocates of the parliament of Normandy, into which he was admitted in 1636; so that he was employed in every cause of importance. In 1677 he was appointed commissioner for the affairs of religion, and discharged the office with great honour. He was highly esteemed as an author, as well as an advocate; and in 1678 he published the "Coutume de Normandie," with ample commentaries, of which a second edition, in 2 vols. folio, was published in 1694. At the same time was published a third edition of his "Traité des Hypotheques," a Treatise on Mortgages. He died at Rouen in 1695. Gen. Dict.

BASNAGE, SAMUEL, DE FLOTTEMANVILLE, son of Antony, was first co-pastor with his father at Bayeux, and afterwards at Zutphen. He was eminent for his learning; and published in Latin a continuation of Casaubon's Critical Examination of Baronius's Annals, entitled "De Rebus Sacris et Ecclesiasticis Exercitationes Historico-criticæ," Ultraject. 4to. 1692; and also "Annales Politico-Ecclesiasticæ," 3 vols. folio, 1706. He died in 1721. Gen. Dict. Nouv. Dict. Hist.

BASNAGE DE BEAUVAL, JAMES, eldest son of Henry, the most illustrious of the name, and sister, says Voltaire, for being minister of state than of a parish, was born at Rouen in 1653. Having acquired a competent knowledge of Greek and Latin, and several modern languages, he went, at the age of seventeen, to Geneva, where he studied philosophy and divinity. Upon his return to Rouen, he commenced the exercise of his profession as pastor of the church in 1676, and in consequence of the revocation of the edict of Nantes, retired to Holland, and settled as minister at Rotterdam. Such was the reputation he acquired for political sagacity, that when the Abbé du Bois came to the Hague, in 1706, under the character of ambassador plenipotentiary, to negotiate a defensive alliance between France, England, and the States-General, he was ordered by the duke of Orleans, regent of France, to consult Mr. Basnage, and to be directed by his advice: and as a reward for his assistance on this occasion, he obtained a restitution of his estate in France. His works are very numerous and valuable; the principal are as follow, viz. "A History of the Church," in French, 2 vols. Rotterdam, 1699; "The History of the Reformed Churches, part of the above work, printed separately in 2 vols. 4to. 1725; "The History of the Jews, from Jesus Christ to the present time, being a continuation of the history of Josephus," written in French; of this work, distinguished by erudition and critical skill, the best edition is the second of the Hague, in 15 vols. 12mo. 1715; "The Republic of the Hebrews," 3 vols. 8vo. Amst. 1705; "Jewish Antiquities," 2 vols. 8vo. 1713; "Dissertation on Duels and Chivalry," 8vo. 1720; "Annals of the United Provinces, since the Peace of Munster," 2 vols. fol. Hague, 1719 and 1726; "A Treatise on Conscience," 2 vols. 8vo.; "Sermons;" "On the Holy Communion;" "Thesaurus Monumentorum Ecclesiasticum et Historicorum, &c." fol. 4 vols. Amst. 1725, being a new edition of the "Lectiones Antiquæ" of Henry Canisius, enriched with learned prefaces and remarks. The matter of Basnage is good, but his style, though sufficiently perspicuous, is stiff and inelegant. In the latter part of his life he removed to the Hague, and died there in 1723. He was polite and affable, benevolent and friendly, and more mild in his disposition than most contro-

proverbalists. Many of his writings are esteemed equally by catholics and protestants. Gen. Dict. Nouv. Dict. Histor.

BASSAGE DE BEAUVAIL, HENRY, younger brother of the preceding, was born at Rouen in 1659, and became a counsellor in the parliament of Normandy. Attached to his religious profession he quitted his prospects at the bar, and took refuge in Holland, where he published in 1684, a small but valuable tract "On Religious Toleration." He also wrote a sequel to the "Nouvelles de la Republique des Lettres" of Bayle, under the title of "L'Histoire des Ouvrages des Savans," commencing in 1687, concluded in 1709, and comprehending 24 vols. 12mo. This work is reckoned judicious and impartial, but the writer's own reflections are sometimes intermixed with those of the authors whose works he reviews, that they cannot be easily distinguished. His new edition of "Furetiere's Dictionary," 3 vols. fol. was printed in 1701. He died at the Hague in 1710. Gen. Dict. Nouv. Dict. Histor.

BASON, PELVIS, in *Anatomy*. See PELVIS.
BASON, or *dish*, among *Clay Grinders*. These artificers use various kinds of basons, of copper, iron, &c. and of various forms, some deeper, others shallower, according to the foci of the glasses that are to be ground. In these basons convex glasses are formed, as concave ones are formed on spheres or bowls.

Glasses are worked in basons two ways. In the first, the bason is fitted to the arbor, or tree of a lathe, and the glass (fixed with cement to a handle of wood) presented and held fast in the right hand within the bason, while the proper motion is given by the foot of the bason. In the other the bason is fixed to a stand or block, and the glass with its wooden handle moved. The moveable basons are very small, seldom exceeding five or six inches in diameter; the others are larger, sometimes above ten feet in diameter. After the glass has been ground in the bason, it is brought smoother with greas and emery: and polished first with tripoly, and finished with paper cemented to the bottom of the bason. See GRINDING.

BASON, among *Hatters*, is a large, round shell, or case, ordinarily of iron, placed over a furnace; wherein the matter of the hat is moulded into form.

The hatters have also basons for the brims of hats, usually of lead, having an aperture in the middle, of a diameter sufficient for the largest block to go through.

BASON, in *Hydraulics*, is also used on various occasions for a small reservoir of water: as the bason of a jet-d'eau, or fountain; the bason of a port, of a bath, &c. which but Vitruvius calls labrum. Basons are made either with clay, cement, or lead; but they are most usually made with clay. In the making of them this way, the diameter must be made four feet longer on each side than the bason is to be. This will be taken up by the walls of clay. For the same reason, it must be dug two feet deeper than the intended depth of the water; because it is to be laid over eighteen inches thick with clay, and six inches with gravel and paving. The wall is to be made with shards, rubbish, or flints, with the natural earth for mortar; and the clay must be well worked, and trod firmly down with the naked feet.

The way of making them with cement is, to allow one foot nine inches every way for the work; then cut the banks perpendicularly, and raise a wall of masonry a foot thick, made of pebble stones, or the like, laid in mortar of lime and sand; the bottom is then to be covered to the same thickness; and then the solid lining of the cement is to be backed up against the walls, and over the bottom. This is to be made of small flints in beds of mortar made of lime and cement. When this solid is eight inches thick, it must be plastered over the whole surface with cement well sifted, before it be mixed

with the lime; and with this it is to be wrought over smooth with a trowel. The proportion of this cement should be two-thirds of the cement, or powdered tile, to one-third of lime; and this cement has the property of hardening so under water, that it will become like stone or marble, and it will not be subject to decay for a long time.

After the finishing, the bason should, for four or five days, be anointed over very often with oil, or bullock's blood, to keep it from flaking or cracking in the drying; and after this, the water should be let in as soon as may be.

The leaded basons are made with walls a foot thick, and a bottom of half a foot. These must be of rubble stones, cemented with plaster; for the lime will injure and eat the lead. The sheets of lead are to be spread over these walls and bottom, and seamed with solder. These basons, however, are but little in use now, from the expence of making them, and the danger of the lead being stolen.

The waste pipes of fountains ought always to be made large enough for fear of chinking. When the waste water is to be carried off into common sewers, it may be carried away in drains, or earthen pipes; but when it is to serve for basons that lie below it, it is to be conveyed in leaden ones. Miller.

There are divers sorts of basons; as

BASON figured, that whose plan or circumference makes several turns and returns, either straight, circular, or the like. Such are most of the basons of fountains at Rome.

BASON with a balustrade, that whose cavity is surrounded with a balustrade of stone, marble, brass, or the like.

BASON with a trench, or *Lassin à rigole*, that whose border being of marble, or other stone, has a trench cut in it, from whence, at certain distances, springs out a thread of water, which lines the trench, and forms a kind of nape or gargle around the balustrade. Such is that of the fountain of the rock of the Belvidere at Rome.

BASON en coquille, that shaped like a shell.

BASON is likewise used for a DOCK.

BASON of the sea. See SEA.

BASON, side by the, in *Commerce*, at Amsterdam, is used for the public sides made under the direction of the ven du meester; thus called, by reason that, before adjudging the lot or commodity to the last bidder, they usually strike a brass bason to give notice of it.

BASON harbour, in *Geography*, lies on the east side of Lake Champlain, in the township of Ferrisburg, and state of Vermont, $4\frac{1}{2}$ miles south-westerly from the mouth of Otter creek.

BASONS of a balance, in *Mechanics*, two pieces of brass, or other matter, fastened to the extremities of the strings; the one to hold the weight, the other the thing to be weighed.

BASOVA, in *Geography*, a town of Siberia, on the river Lena, 20 miles south of Orienga.

BASQUA, a large town of Hindostan, belonging to the district of Bhillah, in the route from Agra to Oujin.

BASQUES, LRS, a country of France, before the revolution, situate between the sea, Spain, the river Adour, and Beam towards the Pyrenean mountains, and comprehending Labour, Lower Navarre, and the district of Soule.

BASQUE ROAD lies on the coast of France, south-east from the island of Rhé, north-east from the island of Oleron, north from the island d'Aix, and south from the west point of the entrance into Rochelle, and directly west without the bay of Chateillon.

BASQUEVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Dieppe, 3 leagues S.S.W. of Dieppe, and $7\frac{1}{2}$ N.N.W. of Rouen.

BASRAH. See **BASSORA.**

BASROUCHE, a town of Persia, in the province of Taberistan, 27 miles west of Fa abat.

BASS, among *Gardeners*, a soft kind of sedge or rush, used in binding plants, &c.

Bass, in *Geography*, an island, or insulated rock, on the coast of Scotland, near the mouth of the frith of Forth, at a small distance from the town of North Berwick in East Lothian. On the south side it has a conical form, and towards the north it tremendously overhangs the sea. The castle, or ancient state prison, is on the edge of the precipice. It is accessible only on the south-west side, and here only by one person at a time, with the assistance of a rope or ladder. On the top of it is a spring; and a cavern passes through the rock from north-west to south-east. This island is about a mile in circuit, and in summer abounds with birds and their eggs, &c. The inland geese arrive here in March, and retire in October or November. It contains a small warren for rabbits, and affords pasture for a few sheep. At the revolution it was supported by a party of the adherents of king James, and it was the last place in the three kingdoms that submitted to the new government; upon which its fortifications were neglected. This island is the south entrance into the frith of Forth; and the island of May, seven miles from it, at N.N.E. easterly is the north entrance. N. lat. $56^{\circ} 3'$. W. long. $2^{\circ} 35'$.

Bass Harbour, a harbour of Mount Desert island, in the district of Maine, North America, seven miles from Soil Cove.

Bass Strait, so called from its discoverer Mr. Bass, a surgeon, is more than 30 leagues wide, containing a chain of small islands that run north and south, and separates Van Diemen's land, hitherto considered as its southern extremity, from New Holland. Mr. Bass, accompanied by Mr. Flinders, a naval gentleman, entered this strait between the latitudes of 39° and 40° south, and actually circumnavigated Van Diemen's land. This discovery serves to expedite the passage from the cape of Good Hope to port Jackson: for, although a line drawn from the cape to 44° of south latitude, and to the longitude of the fourth cape of Van Diemen's land, would not sensibly differ from one drawn to the latitude of 40° , to the same longitude; yet a ship will be four degrees nearer to port Jackson in the latter situation, than in the former. But besides a saving of four degrees of latitude along the coast, the passage through this strait would avoid the north-east winds, which have retarded and endangered ships on opening the sea round the fourth cape and cape Pillar. This strait likewise presents another advantage. From the prevalence of the north-east and easterly winds off the fourth cape, many suppose that a passage may be made from thence to the westward, either to the cape of Good Hope or to India; but the fear of the great unknown bight between the fourth cape and the south-west cape of Lewen's land, lying in about 35° south and 113° east, has hitherto prevented the trial from being made. The strait evades a part of this danger, by presenting a certain place of retreat, should the ship be oppok by a gale at the first essay; and should the wind come at south-east, she need not fear making a good stretch to the W.N.W., which course, if made good, is within a few leagues of going clear of all. There is besides King George the Third's sound, discovered by Capt. Vancouver, situate in S. lat. $35^{\circ} 3'$, and E. long. $118^{\circ} 12'$; and it is hoped, that a few years will disclose many others upon the coast, as well as confirm or disprove the conjecture that a still larger than Bass strait dismembers New Holland. Collins's Account of New South Wales, p. 192, 193.

BASS, in *Music.* See **BASS.**

BASSAD, or **BESD,** an Arabian name for the purple *fucus* of the Greeks, used by the women to paint their cheeks, and by the dyers of cloths. It has been so far misunderstood by late authors as to be interpreted by the word coral; but the error of this is evident, since coral has none of these properties. See **MARGIAN.**

BASSAIM, in *Geography.* See **BASSEEN.**

BASSAMUER ROCK lies on the coast of France, in the English channel, and is a shoal that bears about a league N. by W. from La Clarte church, near the point so called, to the south from the seven islands.

BASSAN, GIACOMO, in *Biography*, a celebrated painter, whose real name was Giacomo de Ponte, was called Bassan from the town of Bassano on the river Brenta, where his father lived and followed the same profession. He was born in 1510, and became a disciple of Bonifacio; and after having improved himself in his art by studying and copying the works of Titian and Parmeggiano at Venice, he returned to his native town. Here he formed a style different from that of his masters, and guided by his own genius, he assumed a manner of colouring and designing peculiar to himself, and copied all his objects from nature. His subjects were generally taken from such parts of scripture as afford the rural scenery of animals and landscape connected with some story; such as the journeyings of the patriarchs, the Israelites in the desert, the flight of Joseph and Mary into Egypt, &c. In all these subjects his figures were well designed; most of them were formed from his wife, children, and servants, and the animals in his court-yard; and they had of course a pleasing resemblance of nature. Although his compositions cannot boast of any great degree of elegance or dignity, they are distinguished by force and truth; his colouring was admirably lively and natural; and his chiaro-scuro and perspective were correctly displayed. His touch was free and spirited; and in his landscapes his distances were always true. Although he had many excellencies, his drawing was incorrect, and his draperies were destitute of variety. His works are easily discriminated from those of other painters, by the similitude of characters and countenances in the figures and animals; by his taste in the buildings, utensils, and draperies, and by a violet or purple tint that predominates in every one of his pictures. Bassan painted much, and with ease; so that his pictures were sent by wholesale to merchants, who dispersed them over Europe. His real pictures, however, are not common; as many of those that are called originals are copies by his sons, who were inferior to himself, or by some painter of meaner abilities. Bassano practised also in portrait, and painted several excellent likenesses of the doges of Venice, of Ariosto, Tasso, and other persons of eminence. His house at Bassano, to which he was attached, and which the solicitations of the emperor Randolph could not induce him to leave, was the place of resort to many persons of distinction, and the receptacle of the arts, particularly of music, of which he was a master. In his private conduct Bassan was regular; and his charity was so profuse, that his wife was under a necessity of restraining his liberality. He lived to the age of 82, and died in 1592. Several of his capital pieces are in the churches of Bassano, Venice, Vicenza, and other towns of Italy. Some of his smaller works may be found in most of the principal collections of Europe; but those that are really originals fetch a high price. Many of them have been engraved.

Giacomo Bassan had four sons, who were painters. *Franco*, the eldest, was the most eminent. He was born in 1550. He painted in the style and manner of his father, and

and greatly excelled his brothers in designing, drawing, and colouring. He was employed in the church of St. Mark at Venice, in conjunction with Tintoretto and Paolo Veronese. By incessant application he increased the natural melancholy of his disposition, and put an end to his life in 1594, by throwing himself out of a window. *Leandro* was born in 1588, settled at Venice, painted in the style of his father and brother, but with inferior merit, and particularly excelled in portraits. The portrait of the doge Grimani procured for him the honour of knighthood. His life was irregular, and he distressed himself by a constant suspicion of the intention of his companions to poison him. He died in 1623. The other two brothers, viz. *Giovanni Battista* and *Girolamo*, the former born in 1553 and dying in 1613, and the latter born in 1560 and dying in 1622, chiefly employed themselves in copying the works of their father and eldest brother. Pilkington.

BASSANI, GIAMBATISTA, in *Musical Biography*, was chiefly known in England, at the beginning of the last century by his *Motets*, which were more graceful and pleasing than those of any of his countrymen, except Caillini and Stradella. But he has many titles to an honourable place in musical history. He was not only author of thirty-one different works in favour all over Europe during the limited longevity of musical productions, but the first composer for the violin in Italy, who seems to have written for it with the spirit and intelligence of a real master of the instrument. He was a native of Bologna, maestro di capella of the cathedral, *Academico Filarmonico* of that city, and violin-master to Corelli. Bassani, who flourished from about the year 1675 to 1703 (the date of his last work), was a man of extensive knowledge and abilities in his art; having been not only a successful composer for the church, the theatre, and the chamber, but an excellent performer on the violin, as we were assured by Padre Martini his townsman, who was old enough to have formed his opinion from those who had often heard him perform. And, indeed, his sonatas for the violin, and accompaniments for that instrument to his masses, motets, psalms, and cantatas, manifest a knowledge of the finger-board and bow, which appears in the works of no other composer, anterior to Corelli, which we have been able to find; and the lovers of the pure harmony and simple melody of that admirable master would still receive great pleasure from the performance of Bassani's sonatas for two violins and a base; in which they would hear, not only the general musical language of the time, but the mild accents and grateful tones of Corelli's own mellifluous voice.

BASSANIA, in *Ancient Geography*, a town of Macedonia, on the frontiers of Illyria, situate, according to Livy, about 5 miles from Lissus, and belonging to the Cavians.

BASSANO, in *Geography*, a town of Italy, belonging to the state of Venice, in the Trevisano, on the Brenta, 12 miles north of Vicenza.

BASSANO, a town of Italy, in the state of the church, near which Dolabella defeated the Etruri and Boii, 3 miles west of Orta.

BASSANTIN, JAMES, in *Biography*, a Scots astronomer, in the sixteenth century, was the son of the laird of Bassantin, in the Mers, and born in the reign of king James IV. The rudiments of knowledge, and particularly of that skill in various branches of the mathematics for which he was afterwards so distinguished, he acquired in the university of Glasgow. For further improvement he travelled through various parts of the continent, and at length settled at Paris, where he taught the mathematics with applause in the university of that city. During his abode in this city, he imbibed that zeal for the delusions of judicial astrology,

which was then so prevalent, and which few astronomers had judgment or resolution sufficient to discountenance. After having acquired great reputation and some fortune in France, he returned to his own country in 1562. At York, in his journey through England, he had an interview with sir Robert Melvil, brother of sir James Melvil, who, in his "Memoirs," relates the conversation that passed between them. It appears that Bassantin communicated to Melvil certain predictions relating to his mistress, Mary queen of Scots, who was then treating with Elizabeth after having taken refuge in her dominions. Of these predictions some were true, and others were false; but such was the political sagacity of Bassantin, that we may ascribe them to this source rather than to his skill in the occult sciences, for which however he seems to have been ambitious of being thought distinguished. Of his mode of life during the remaining period of it, we have no account; but he appears to have been a zealous protestant, and a partisan of the earl of Murray. He died in 1568. To a slight acquaintance with polite literature, Bassantin added a considerable degree of mathematical and astronomical knowledge, considering the dark period in which he lived. His principal work in astronomy was written in French, and translated into Latin by Tormaeus, and published at Geneva by 1599, folio, under the title of "Astronomia, Jacobi Bassantini Scoti, opus absolutissimum, &c. &c." He also published "Paraphrase de l'Astrolabe, avec un amplification de l'usage de l'Astrolabe," or an ample explanation of the astrolabe, printed at Lyons in 1555, and at Paris in 1617, 8vo.; "Super Mathematica Genethliaca," or of the calculation of nativities; "Arithmetica;" "Musica secundum Platoni;" and "De Mathesi in genere." Biog. Brit.

BASSANUS, in *Ornithology*, a species of PELECANUS, as large as a common goose, with a wedge-shaped tail; body white; bill and primary quill-feathers black; and face blue. Gmelin. Latham, &c.

This is the common gannet, or soland goose; a bird found in great plenty on all the northern coasts of Britain, but rather less common to the southward. The adult birds have the plumage nearly all white; but during the first years it is of a dusky colour, and only speckled with white. The bill is blueish-ash colour, about six inches in length, and has the nostrils placed in a furrow; the mouth within is black; the throat is bare; and the skin very dilatible, forming a pouch of sufficient size to contain five or six herrings; the legs are black, marked with a stripe of pea-green before; and the claw of the middle toe is pectinated. The male and female are very much alike in plumage. The gannet is particularly abundant in the isle of Ailsa in the firth of Clyde; the rocks adjacent to St. Kilda; the stalks of Soulliskerry, near the Orkneys; the Skelig isles off the coasts of Kerry, Ireland; and the Bass island in the firth of Edinburgh. Dr. Hervey gives some account of the latter in these words. "There is a small island, called by the Scotch *Bass island*, not more than a mile in circumference; the surface is almost wholly covered during the months of May and June with nests, eggs, and young birds; so that it is scarcely possible to walk without treading on them; and the flocks of birds in flight are so prodigious as to darken the air like clouds; and their noise is such that you cannot without difficulty hear your next neighbour's voice. If you look down upon the sea from the top of the precipice, you will see it on every side covered with infinite numbers of birds of different kinds, swimming and hunting for their prey; if in sailing round the island you survey the hanging cliffs, you see in every cragg or fissure of the broken rocks innumerable birds of various sorts and sizes, more than the stars

stars of heaven when viewed in a serene night ; if from afar you see the distant flocks either flying to or from the island, you would imagine them to be a vast swarm of bees."

"The gannet," observes Dr. Latham, "inhabits the colder parts of this kingdom, and more especially several of the northern isles, and in particular that of Bass in Scotland, whence the name. It generally first makes its appearance in March, and after making a circuit of the island, departs in October or November. This race seems to be in pursuit of the herrings and pilchards, whose motions it watches; and the fishermen know the coming of these fish by the appearance of the birds. That this is the inducement seems probable, as they are likewise seen, in the month of December, as far south as the coast of Lisbon and Gibraltar, plunging for sardinæ. The gannet is also common on the coasts of Norway and those of Iceland, and now and then met with on the southern coasts of Greenland. In America, it is found on the coasts of Newfoundland where it breeds, migrating in winter as far as Carolina: said also to have been met with frequently in the southern ocean; but we are not clear whether the sort meant by them is the common gannet, or the lesser one."

"The gannets," Mr. Pennant remarks, "are birds of passage. Their first appearance in those islands being in March, and their continuance till August or September, according as the inhabitants take or leave their first egg; but in general the time of breeding and that of their departure seems to coincide with the arrival of the herring, and the migration of that fish, which is their principal food, out of those seas."—"I have in the month of August," he adds in another place, "observed in Caithness their northern migrations. I have seen them passing the whole day in flocks, from five to fifteen in each. In calm weather they fly high, in storms they fly low and near the shore; but never cross over land, even when a bay with promontories intervenes, but follow at an equal distance the course of the bay, and regularly double every cape. I have seen many of the parties make a sort of halt for the sake of fishing; then darting headlong into the sea, make the water foam and spring up with the violence of their descent: after which they pursued their route. I enquired whether they ever were observed to return southward in the spring, but was answered in the negative; so that it appears, they annually encircle the whole island."

They are well known on most of our coasts by different names. In Cornwall and in Ireland they are called *gannets*, and by the Welsh *gan*. It comes on the coasts of Cornwall in the latter end of the summer or beginning of Autumn, hovering over the shoals of pilchards that come up through the St. George's channel from the north sea. The gannet seldom comes near the land, but is constant to its prey; and when the pilchards retire, which happens about the end of November, they are seen no more.

The nest of the gannet is composed of various materials, such as grass, and water-plants intermixed with any thing the bird finds floating on the water. Each bird, if undisturbed, would lay only one egg in the year; but if that be taken away, they will lay another; and if that be taken away also, they will lay a third, but no more. The young gannets, as well as the eggs, are eaten. Martin assures us, that the inhabitants of St. Kilda consume annually no less than 22,600 young birds of this species, besides an amazing quantity of their eggs; these being their principal support throughout the year: they preserve both eggs and fowls in pyramidal stone-buildings, covering them with turf ashes to preserve them from moisture. This is a dear-bought food, and earned at the hazard of their lives, either

by climbing the most difficult and narrow paths, where to appearance they barely cling, and that too at an amazing height above the raging sea; or else, being lowered down from above, they collect their annual provision, thus hanging midway in the air, and placing their whole dependence on the uncertain footing of one person who holds the rope by which they are suspended at the top of the precipice. The young birds are a favourite dish with the North Britons in general: during the season they are constantly brought from the Bass isle to Edinburgh, and are roasted and served up a little before dinner as a whet: the price they are sold for in the markets is about twenty-pence a piece.

The following account of the gannets in the isle of St. Kilda is given by Mr. Macauley. "The rocks are in summer totally covered with soland geese and other fowls, and appear at a distance like so many mountains covered with snow. The nests of the soland geese, not to mention those of other fowls, are so close, that when one walks between them, the hatching fowls on either side can always take hold of one's clothes; and they will often sit till they are attacked, rather than expose their eggs to the danger of being destroyed by the sea-gulls: at the same time an equal number fly about, and furnish food for their mates that are employed in hatching; and there are, besides, large flocks of barren fowls of the different tribes that frequent the rocks of St. Kilda.

"The soland geese equal almost the tame ones in size. The common amusement of the herring-fishers shows the great strength of this fowl. The fishers fix a herring upon a board, which has a small weight under it to sink it a little below the surface of the sea: the soland goose observing the fish, darts upon it perpendicularly; and with so much force, that he runs his bill irrecoverably through the board, and is taken up directly by the fishers.

"The soland geese repair to St. Kilda in the month of March, and continue there till after the beginning of November. Before the middle of that month they, and all the other sea-fowls that are fond of this coast, retire much about the same time into some other favourite regions; so that not a single fowl belonging to their element is to be seen about St. Kilda from the beginning of winter down to the middle of February. Before the young soland geese fly off, they are larger than their mothers, and the fat on their breast is sometimes three inches deep. Into what quarter of the world these tribes of wild fowl repair, after winter sets in, whether into the northern ocean, the native country and winter-quarters of herrings in general, or into some other region near the sun, or whether they be of the sleeping kind, they who pry into the mysteries of natural history, or have conversed much with writers of voyages can best explain. I shall only pretend to say that these different nations of the feathered kind are taught to chuse the properest habitations and feeding places, and to shift their quarters seasonably by the unerring hand of God.

"From the account given above of the multitudes of sea-fowls that seek their food on this coast, we may justly conclude that there must be inexhaustible stores of fish there. Let us for a moment confine our attention to the consumption made by a single species of fowls. The soland goose is almost insatiably voracious; he flies with great force and velocity, toils all the day with little intermission, and digests his food in a very short time; he disdains to eat any thing worse than herring or mackrel, unless it be in a very hungry place, which he takes care to avoid or abandon. We shall take it for granted that there are a hundred thousand of that kind around the rocks of St. Kilda; and this calculation is by far too moderate, as no less than twenty thousand

band of this kind are destroyed every year, including the young ones. We shall suppose, at the same time, that the young geese sojourn in these seas for about seven months in the year; that each of them destroys five herrings in a day, a subsistence infinitely poor for so greedy a creature, unless it were more than half supported at the expence of other fishes. Here we have 100,000,000 of the finest fish in the world devoured annually by a single species of the St. Kilda sea-fowls," &c.

In concluding this account of the grunter, it is proper to observe that *le grand feu* of Beller and Buffon, and *great Loby* of Catby, an inhabitant of the sea-shores of Florida, is supposed to be the young or at least a variety of *pleuronectes Balthicus*; and that observed by navigators so common on Ascension island *pleuronectes pinnatus*, a different species.

BASSAWES, or *Boxa*, *Schant*, in *Geography*, lie on the west coast of Africa, beginning about west, or to the south of west from Sierra Leone, and running out far to sea in rounds and hollows, so that ships cannot clear them without standing off out of sight of land.

BASSIF, BASS, or LA BASSIE, a town of France, in the department of the north, and chief place of a canton in the district of Lille; ceded by the Spaniards to France by the treaty of Aix-la-Chapelle, in 1763; formerly a place of considerable strength, but dismantled by Louis XIV. It is situated on the Deule, 2 leagues east of Bethune, and 3½ south-west of Lille. N. lat. 50° 53'. E. long. 3° 0'.

BASSE, in *Ichthyology*, the English name of a fish found on some of the British coasts, and named *perca labrax*. Linn. Syst. 482. ed. 12.

BASSE-Cour, in *Building*, a court separated from the principal one, and destined for the stables, coach-houses, and livery-servants.

BASSE-Cour of a country-seat, is the yard or place where the cattle, fowls, &c. are kept.

That where strange creatures of divers sorts are kept for curiosity, is called by the French *menagerie*. The Romans gave the name of *vivarium* to that place, where beasts were kept for the public shows.

BASSE, in *Middle Age Writers*, denotes a collar for cart-horses, made of flags. Hence also the round matted cushions of flags, used for kneeling in churches, are called *basse*; in Kent, a *trush*.

BASSE *de Flute traversiere*, Fr. in *Music*, a side-flute, a fifth below the usual compass of the German flute, now out of use in France; and we never remember its use in England.

BASSE-Flute. When, at the beginning of the last century, the flute-à-bec, or common flute, was in general use and favour, there were flutes of every size and pitch. F natural being the best in tune, and the easiest key on the common flute, all songs and other favourite airs were transposed for the flute into that key, or into C natural, at the bottom of the plate, when printed. The base flute was an octave below this F, and the octave flute an octave higher. See FLUTE.

BASSE *Tonique*, the base of the key-note, or Tartini's third found, produced by the concurrence of two treble notes perfectly in tune, and steadily sustained with two voices, violins, flutes, hautbois, or by two strings in double stops on one violin, or two keys on the organ. See TERZA SUONA.

BASSEEN, or BAÇAIM, in *Geography*, a fortified city, situate on the point of the continent on the western coast of the peninsula of India, opposite to the north end of Salfetta. It lies in N lat. 19° 19', and under the same meridian as Bombay. This place fell into the hands of the English, after a smart siege in 1780, but was restored to the Mahrattas,

together with all the other conquests made on that side of India, at the peace of 1783; Salfetta and the small islands excepted.

BASSENTO, a river of Italy, in the kingdom of Naples, which runs into the Grati, near Colenza.

BASSERSTORF, a town of Swisserland, in the canton of Zurich, 4 miles N.E. of Zurich.

BASSET, or BASSETTE, a game with cards, said to have been invented by a noble Venetian; for which he was banished. It was first introduced into France, by signior Justini, ambassador of Venice in 1674. Severe laws were made against it by Louis XIV, to elude which they disguised basket under the name of *four & come*, that is, for and against; which occasioned new arrests and prohibitions of parliament. The parties concerned in it are, a dealer or banker, his assistant, who supervises the losing cards, and the punter, or any one who plays against the banker.

Besides these, there are other terms used in this game; as, 1. The *bat*, or *bat*, which is the first card turned up by the *tailleur* belonging to the pack; by which he gains half the value of the money laid down on every card of that sort by the punter. 2. The *couch*, or first money which every punter puts on each card; each person that plays having a book of thirteen several cards before him, on which he may lay his money, more or less, at discretion. 3. The *paroli*, which is, when a punter having won the first stake, and having a mind to pursue his good fortune, crooks the corner of his card, and lets his prize lie, aiming at a *jeu et le va*. 4. The *meure*, when having won the first stake, the punter is willing to venture more money on the same card. 5. The *pay*, when the punter having won the first stake, be it a shilling, half crown, guinea, or whatever he laid down on his card, and not caring to hazard the *paroli*, leaves off, or goes *the pay*; in which case, if the card turn up wrong, he loses nothing, having won the couch before; whereas, if it turn right, he by this adventure wins double the money staked. 6. The *apico*, much the same with *paroli*, and used when a couch is won by turning up, or crooking the corner of the winning card. 7. *Sept et le va*, the first great chance or prize, when the punter having won the couch, makes a *paroli*, and goes on to a second chance; so that if his winning card turns up again, it comes to *sept et le va*, which is seven times as much as he laid down on his card. 8. *Quinze et le va*, is the next higher prize, when the punter, having won the former, is resolved to push his fortune, and lay his money a second time on the same card, by crooking another corner; in which case, if it come up, he wins fifteen times the money he laid down. 9. *Trent et le va*, is the next higher prize, when the punter crooking the fourth corner of his winning card, if it turn up, wins thirty-three times the money he first staked. 10. *Soixant et le va*, is the highest prize, and entitles the winner to sixty-seven times his first money; which, if it were considerable, stands a chance to break the bank; but the bank stands many chances first of breaking the punter. This cannot be won, but by the *tailleur's* dealing the cards over again.

The rules of the game of basket are as follow: The banker holds a pack of fifty-two cards, and having shuffled them, he turns the whole pack at once, so as to discover the last card; after which he lays down all the cards by couples. The punter has his book of thirteen cards in his hand, from the king to the ace; out of these he takes one card or more at pleasure, upon which he lays a stake. The punter may, at his choice, either lay down his stake before the pack is turned, or immediately after it is turned, or after any number of couples are down. Supposing the punter to lay down his stake

flake after the pack is turned, and calling 1, 2, 3, 4, 5, &c. the places of those cards which follow the card in view, either immediately after the pack is turned, or after any number of couples are drawn. Then if the card, upon which the punter has laid a flake, comes out in any odd place except the first, he wins a flake equal to his own. If the card, upon which the punter has laid a flake, comes out in any even place except the second, he loses his flake. If the card of the punter comes out in the first place, he neither wins nor loses, but takes his own flake again. If the card of the punter comes out in the second place, he does not lose his whole flake, but only one half; and this is the case in which the punter is said to be faced. When the punter chooses to come in after any number of couples are down, if his card happen to be but once in the pack, and is the last of all, there is an exception from the general rule; for though it comes out in an odd place, which should entitle him to win a flake equal to his own, yet he neither wins nor loses, from that circumstance, but takes back his own flake.

This game has been the subject of mathematical calculations. Mr. De Moivre solves this problem; to estimate at basset the loss of the punter under any circumstance of cards remaining in the stock, when he lays his flake, and of any number of times that his card is repeated in the stock. From this solution he has formed a table, shewing the several losses of the punter in whatsoever circumstances he may happen to be. See Doctr. of Chances, p. 63.

From this table it appears, 1. That the fewer the cards are in the stock, the greater is the loss of the punter. 2. That the least loss of the punter, under the same circumstances of cards remaining in the stock, is when his card is but twice in it; the next greater when but three times; still greater when four times; and the greatest when but once. The gain of the banker upon all the money adventured at basset, is 15s. 3d. per cent. De Moivre, Doctr. of Chances, p. 69. edit. 3.

BASSET, in *Zoology*, the name given by Buffon to that kind of dog which is called in England the turnspit, *canis vertagus* Gmelin. Of this kind he makes two varieties; le basset à jambes droites, and le basset à jambes torfes; the first having straight legs, and the last crooked ones.

BASSETTERE, in *Geography*, a general name given by the French to the low lands of the West India islands; such are the S.W. part of the two parts of Guadaloupe island, separated by a small arm of the sea, called the Salt river; and also the N.W. part of the island of Martinico.

BASSETTERE Town, a sea-port town on the S.W. coast of the island of St. Christopher in the West Indies, and capital of the island, situated at the mouth of a river, opening into a bay, called Basseterre road. The town contains about 800 houses, and is defended by three batteries. N. lat. 17° 24'. W. long. 62° 37'.

BASSETTERE Town, is also a sea-port town on the S.W. coast of the island of Guadaloupe, regularly built, with some handsome houses, and defended by a citadel. N. lat. 15° 59' 35". W. long. 61° 59' 15".

BASSETTING, in the *Coal Mines*, denotes the rise of the vein or coal towards the surface of the earth, till it come within two or three feet of the surface itself.

This is also called by the workmen *cropping*, and stands opposed to *dipping*, which is the descent of the vein to such a depth that is rarely, if ever, followed to the end.

BASSI, ANGELO, in *Biography*. See **POLIZIANO**.

BASSI, LAURA, an Italian lady, distinguished by her acquisitions, was the wife of Dr. Joseph Verati of Bologna. She understood the Greek, Latin, and French languages, as

well as her own, and was eminent for her literature and science. In 1732, she was honoured with the doctorial dignity, and she kept up a correspondence with many learned persons in Europe, who admired her talents and accomplishments. She commenced a course of lectures in philosophy in 1745, and continued them to her death. Her morals were pure, and her character amiable; and she was liberal in her acts of charity to the poor and orphans. She died at an advanced age at Bologna in 1778. Nouv. Dict. Hist.

BASSIA, in *Botany*, so named by Koenig in honour of Ferdinando Bassi, curator of the botanic garden at Bologna. Lin. gen. Reich. n. 645. Schreb. 805. Juss. 132. Gærtn. t. 104. Class and order, *dodecandria monogynia*. Nat. Ord. *Dumose*; *Sapota* of Juss. Geog. Char. Cal. perianth four-leaved; leaflets coriaceous, ovate, permanent. Cor. mono-petalous, bell-shaped; tube inflated, ovate, fleshy; border shorter than the tube, eight-parted; divisions ovate, almost upright. Stam. filaments sixteen; eight below the jaws, and eight in the middle of the tube; anthers linear, sagittate, acute, villose on the inside, shorter than the corolla. Pist. germ superior, ovate; style subulate, twice as long as the corolla; stigma acute. Per. drupe fleshy, milky. Seeds, nuts five, oblong, three-cornered.

Ess. Char. Cal. four-leaved. Cor. eight-cleft; tube inflated. Stam. 16; drupe five-seeded. (Berry five-celled, with a seed in each cell. G.)

Species, 1. *B. longifolia*. Illippe Malabar. and Miele Ceylonensibus. "Leaves ovate-lanceolate, peduncles axillary." A lofty tree, with the utmost branches recurved, thickish, and covered with a grey down; leaves on them alternate, approximating, petioled, entire, veined, naked, half a foot long, and deciduous; petioles roundish, short; peduncles axillary, from one to five, filiform, one-flowered, upright; after flowering, prolonged and pendulous; berry oblong, slightly compressed, smooth, shining, and yellow, with a white band. A native of Malabar and Ceylon. 2. *B. dubia*. Seed large, half-moon shaped; flattened like a lens, smooth and shining, of a dark chestnut colour, excepting an oblong, rugged, umbilical area, which is almost white. The shell is thick, stony, and very hard. The seeds of bassia are not easily distinguished from those of sapota, without attending to the albumen, of which bassia is entirely destitute; and the inner investment is also commonly wanting. 3. *B. obovata*. Forst. Florul. n. 200. "Leaves obovate; peduncles heaped, terminating." A native of the isle of Tanna, in the South seas. Martyn's Miller's Dict.

BASSIANO, LAURO, in *Biography*, born at Placenza, discovering early a propensity to the knowledge of medicine, was sent to Padua, where he studied under Baptist Monti, and, having performed the usual exercises, in 1544 he was admitted doctor in philosophy and physic. In 1547 he was made professor in those sciences, and acquired considerable reputation as a public teacher. Going to his house, in 1562, he was assaulted by an assassin, who killed him by stabbing him in several parts of his body with a bayonet. He left several publications, of which the principal are, "Iatrologia five dialogi duo, in quibus de universæ artis medicæ, præcipue vero morborum omnium et cognoscendorum et curandorum absolutissima methodo, differitur," Basilæ 1543, 4to.; "De origine et causa pestis," Patav. 1555, 8vo; "De prodigiis partubus." Haller. Bib. Med. Eloy. Dict. Hist.

BASSIN'S RIVER, in *Geography*, is situated on the coast of Labrador, in North America, nearly opposite to the north point of Newfoundland.

BASSING, a town of France, in the department of the Meurte, and chief place of a canton in the district of Dieuze, 1½ league N.E. of Dieuze.

BASSIUS, HEN. V. in *Biography*, son of Gerard Bassius, or Bass, a surgeon of eminence at Bremen, born in 1690. In 1713, he went to Halle, where he studied medicine under Frederic Hoffman, in 1715 to Strasburg, and two years after to Basse; attaching himself particularly to acquiring a knowledge of the improvements that had been lately made in anatomy and surgery. Returning thence to Halle, he was created doctor in medicine; and soon after professor in anatomy and surgery, which office he continued to hold till the time of his death, March 31st 1754. His works are, "Disputatio de fistula ani sive enteri curanda," Svo. 1718; "Observationes anatomico-chirurgico-medice," Halle 1721, with figures, representing some instruments invented by the author,—a work much commended by Haller; "Tractatus de morbis veneris," Lipsie 1764, Svo.: a posthumous work, to which the editor has added some valuable observations. He also published, in the German language, "Commentaries on Nuck's Art of Surgery," Svo. 1728. Haller. Bib. Anat. et Chir. Eloy. Dict. Hist.

BASSO CONTINUO, in *Mus.* originally meant the accompaniment to the higher parts of a sonata, concerto, or chorus, in whatever style it was written, which served as a base, when the real base was silent; as in fugues, and other movements; to let the accompanier on the organ or harpsichord know what was doing by the other instruments, while his part was at rest. This may still be seen in the organ part (organo) to Corelli's Sonatas, Op. 1ma, which were composed in the seventeenth century, after which the custom was discontinued, there being no instance of it in his other works. Though in the sonatas of Bassani, his master, and in those of Torelli, it is constant. Handel, in his hautbois concertos, and in his twelve grand concertos, calls the ripieno base, basso continuo.

It was to this kind of choral base for the organ or harpsichord, in ecclesiastical music, that the harmony of the whole score, without a treble part, was first expressed by figures over the base notes. Basso continuo, by an awkward translation, is, in English, synonymous with *thorough-base* which see.

It was in the beginning of the seventeenth century that Ludovico Viadana (not Viana, as erroneously written by Roussseau, and copied from him in both editions of the Encyclopedie) one of the most distinguished ecclesiastical composers of that time, invented the indication of chords by figures, in what the Italians call the basso continuo, and the English thorough base, or accompaniment on keyed instruments, lute, harp, and, in recitatives, even violoncellos; but we have found several instances of the minute beginnings of this expedient before the time of Viadana; though he was doubtless the first who drew up general rules for expressing harmony by figures over the base in 1615. Draudius, in an ample list of his ecclesiastical compositions, which were very numerous, tells us of one that authenticates his claim to this invention, which was a collection of all his choral pieces, of one, two, three, and four parts; "with a continued and general base, adapted to the organ according to a new invention, and useful for every finger as well as organist; to which are added short rules and explanations for accompanying a general base, according to the new method." Viadana was therefore the first who composed an organ-base different from the *voice-part*, in the execution of which the new-invented figures enabled the performer to give the fingers the whole harmony of the several parts of a full composition, without seeing the score.

In 1731, Mattheson, in his "*Grosse general basse schule oder der exemplarischen organisten proben*," a treatise on thorough-base, has given a list of twenty-two writers

on accompaniment from the time of its invention in 1606. The invention has been indisputably secured to Viadana in Draudius's Catal. ii. (Draudio Bibliotheca Classica, 2 vols. 4to. Frankfurt 1625.), where there is a list of all his works, and among the rest, "Da. Ludovici Viadani Itali opera omnia facorum concertuum. 1, 2, 3, & 4. vocum basso continuo & generali, organo applicato, novaque inventione pro omni genere et sorte cantorum et organitarum accomodata. Adjuncta insuper in basso generali hejus nove inventionis instructio et facin. la explicatio, Latine, Ital. et Germ. ap. Steinum 4. 1615."

In the list which Mattheson has given of twenty-two authors on accompaniment before 1731, it is observable that only one tract is in English; and that written by Keller a German, who lived in queen Anne's time, and dedicated to Her majesty six sonatas for two flutes and a base.

In Rameau's system, and still less in that of the abbé Feytaud, as the fundamental base can have no melody, but what arises from its own harmony or single common chord, the basso continuo may be regarded as a kind of low treble under the violins and tenor, or as a variation of the fundamental base.

BASSO STROFICO, Ital. a base confined to a few bars or notes, repeated to different and varied treble parts. The English call this kind of monotonous movement a ground. During the seventeenth century, the Italians and their imitators were very fond of writing upon a ground-base; Stradella and Purcell frequently manifested their ingenuity under such restrictions; nor had the fashion quite subsided in Handel's time, as may be seen in the last chorus of his Dettingen Te Deum, and elsewhere in his numerous and admirable works. See GROUND, CIACONA, and CHACONNE.

BASSO CANTANTE, Ital. *Bassifle*, Fr. the vocal base-part, or the base singer in an oratorio, opera, or concert.

BASSO RELIEVO, Italian, *Bas-relief*, French, in *Sculpture*, is the representation of figures on a back ground, in such a manner that no part of them is detached from it; alto relievo, high relief, has the grosser parts attached to the back ground whilst the smaller parts are free from it: some distinguish a third kind, or mezzo relievo, middle relief, between both; although it must be acknowledged that all three kinds are implied, in a general mode of speaking, by the common term of basso-relievo, or bas-relief, because almost all figures in relievo, even alto relievo, are more compressed or flattened than their insulated archetypes in nature. This, like many other terms in the art of design, is of modern date, and was most likely invented or at least compounded and applied, in the eleventh or twelfth centuries, when sculpture and architecture began to revive in Italy, and these kinds of works became a very considerable decoration to the new cathedrals. The Greeks, to whom we must look for the best definitions in this art, as well as the most excellent works, called this species simply *anaglypta*, carved (Pliny, lib. 33. c. 11.); that which we call alto-relievo was distinguished by them from the low-relief, by the word, *toronticton*, rounded. Pliny, l. 34. c. 8.

Basso-relievo, although a considerable province of sculpture, is in a particular manner allied to architecture and under its dominion; as any considerable work of this kind must be made for the pediment, frieze, or pannel of a building, or architectural form, such as a sarcophagus or pedestal: and therefore the general shape of the ground, the distribution and projection of the figures, must be subservient to the surrounding and containing parts, in order that they may produce a beautiful whole.

It is well remarked by the authors of the French Encyclopedie, that "the origin of basso-relievo is confounded with that of the hieroglyphic; that is to say, it owes its birth

birth to figured writing. Under this point of view, it is common to all people, and is found among the most savage. It was invented by necessity, appropriated by religion. The progress alone of the arts of imitation could perfect these primitive signs and give them life. This honour was reserved for the Greeks. In Greece the arts were in some sort the ministers of religion; in Egypt and in Asia they were the slaves. A religious respect for these primitive characters, which worship had sanctified, feared perhaps to change; the ideas in changing the forms to which they were attached: all contributed, among the Egyptians, to retain the arts in a kind of infancy, from which religion prevented them from emerging."

All the larger hieroglyphics engraven in the surface of Egyptian architecture, or on the figures of men and inferior animals, may be considered as basso-relievo: and, as the most simple, it may be consequently of the most ancient kind: because the figure was sunk in such a manner, that the surface of the ground was left, forming an enclosure or outline whose greatest depth was equal to the greatest projection of the figure, which was productive of these advantages. As many of the hieroglyphics were cut in granite, a very brittle marble, it prevented the danger of spoiling the outline in sinking the back-ground, one-third of the labour was saved, and a strong shadow all round the figure, particularly when the sun shone on it, defined its form to the sight. All the temples and palaces enumerated by Ripaud, and described by Denon in the late expedition of the French into Egypt, shew that the greater part of those edifices, as well as inferior works, were covered with hieroglyphics, or sacred figure-writing in the kind of bas-relief above described: the largest of these formed regular ornaments to the friezes, centres over the doors, corresponding tablets, or pannels where the symmetry of the architecture required. The principal of these figures, according to a comparison of what we find in Orus Apollo, Iamblichus on Hieroglyphics, and other authors, with the hieroglyphics themselves, seem to be the representation of some characteristic or attribute of the divinity, and the operations of his providence in nature, accompanied by acts of adoration: the inferior figures and characters are ranged in lines like writing.

Besides the hieroglyphics, the Egyptians employed bas-relief, with the ground levelled to the lowest part of the figure, to describe the political or military prowess of their heroes, and for other historical purposes. Of this kind are those in the palaces of Karnac, engraved by Denon, and those described in the Bird's Well, of which there is a specimen in the hall of the British Museum. It is in a soft calcareous stone in very low relief: the subject, men slaying oxen. The human figures are in violent action, which they seem to have attempted in historical more than in sacred subjects. Nor is it surprizing that such actions are extravagant, and not well rendered; when we see by the works themselves, that the stock of knowledge which the sculptors possessed, was insufficient to account for the parts of the body by a fine proportion, beautiful outline, and the anatomical changes of appearance in the different circumstances of motion. But the prodigious quantity of this kind of labour still remaining must have occupied the diligence of so many hands for a series of ages, that they could have had little leisure to make advances, either in the sentiment or scientific perfection of their figures. This may account, in part at least, for the execution of the quadruped being better than that of the human figure, which is so much more difficult.

It is necessary to give a general account of the character and style of design in the Egyptian figures, because what is said on this subject will be in a great measure applicable to

the early progress of the arts among the Hindoos, Persians, and Greeks, allowing for some peculiarities in each nation. The arts of design are strictly imitative in the early attempts; and we find in the Egyptian figures, compounded of different animals, that each part is a copy of nature. In the human figure, the body and limbs were represented in general forms. The face, as being the most interesting part of the person, was more minutely expressed. The form of the face was a rounded egg, lines of the eye-brows and lids, simple curves, inclining upwards from the nose, the bottom of the nose and the line of the mouth inclined upward, in the same direction with the eyes. The eyes were full, nearly on a level with the forehead and cheeks, and the lines of the eye-brows, lids, and borders of the eyes, marked with precision. The chin appeared small and bony, the neck round, the shoulders high and broad, except the marking of the breast, little distinction of the muscular forms in any part of the body and limbs, the loins narrow, the limbs round, rather straight and slender, their joints slightly indicated, the hands and feet rather flat, the fingers and toes rounded, without the appearance of joints, and nearly of the same length. According to a figure Denon found, measured by 22 squares in length, the half of the figure each way was from the division of the thighs, the head was rather less than a seventh part of the figure's height. See Denon's Voyage, plate 124, fig. 1.

The quadrupeds on Egyptian monuments, are represented in profile, and in the simplest attitudes. The parts of which those are composed, are fewer and more general than those in the human figure. This is one reason why the Egyptians excelled in their animals; the mechanical manner in which the shoulder is drawn of the lion and sphinx (where they have displayed more anatomy than in any other part) presents a simple, but not just account of the structure of that member of the body: these observations apply to the state of sculpture before the time of Alexander the Great; after which period, it partook of the improvements introduced by its Grecian conquerors.

Basso-relievos are found in India, which decorate the excavations of Ellora and Elephanta in an astonishing profusion. The subjects are sacred, suitable to the temples in which they are carved; the drawing of the figures and their parts bears a strong resemblance to the Egyptian style; but inferior in this, that many of the figures have very large heads, the limbs and bodies disproportioned. It seems likely that the Egyptian hieroglyphics are more ancient, because more simple than the Hindoo basso-relievo; the former having the ground left even with the highest relief, the latter having the ground cut level with the lowest outline of the figure. For the most extensive, accurate, and valuable publications of these subjects we are indebted to the abilities and unwearied labour of our countryman Thomas Daniell, Esq. R. A.

The Persians employed basso-relievo like the other ancient nations as a figured writing, at once to record and represent the symbols of Almighty power and operation, their religious ceremonies, and the prowess of their heroes. The bas-reliefs on the palace of Persepolis and the royal tombs are arranged in lines, horizontal and perpendicular, to answer the double purpose of description and architectural decoration: the style of drawing resembles that of the figures in the later hieroglyphics, although the dresses are extremely different. The Egyptians are particularly distinguished by the hood, the mitre, the full hair artificially curled, the close tunic, the apron of papyrus; the Hindoos by the necklaces, bracelets, and anklets; the Persians have long beards and hair ending in small curls, caps, full tunics with regular folds and large sleeves; the Medes in the same ruins of Persepolis have close tunics. The drapery in these bas-reliefs is rather

more like nature than that in the Egyptian hieroglyphics and other bas-reliefs, but this may be the consequence of what the artists had more frequently to imitate, instead of a proof that the arts were more advanced in Persia than in Egypt, which seems still less probable when we consider, the different positions of the human figure, the variety and extent of the historical compositions in the palace of Karnac, the Theban tombs, &c. and the exquisitely neat and perfect execution of the hieroglyphics on the obelisk of Sesostris, lately erected on Monte Citorio by Pius the VIth, far exceeding the workmanship of any figure at Persepolis. See Denon's Egypt. Le Bruyn's Travels, vol. 2.

The earliest Greek sculpture extant is still more like the Egyptian in the principles of design, than that of any other nation. The face of the human figure has the same oval, the features described by the same simple curves, the eye kept full as the easiest to execute, being more distinguished by the lines of which it is formed, than by its appearance in profile; and nearly the same general parts represented the body and limbs. That there should be this similarity in different nations in the imitative arts, is strictly agreeable to reason; because conformably to their limited progress in science, they will represent in a simple and gross manner those objects, the detail of which their minds have neither comprehended nor understood, and which in that stage of progress the hand would be as little likely to perform with the requisite accuracy. It is equally reasonable to expect such imitations should resemble each other; being made from examples of general likeness, and done without the influence of manner, which is the consequence of imitating art instead of nature.

It is most likely that some imitations in sculpture of the human figure were made in Greece, previously to the introduction of letters by Cadmus, because modern travellers have found such imitations among many barbarous people unacquainted with letter-writing, and because the Greeks appear to have used figure-writing before they were acquainted with letters: see Wolf's *Prolegomena to Homer*, page 81; who believes that figure-writing only was known in the time of Homer. But it is equally certain that small bronze figures exist with inscriptions of Cadmean letters on them, which are very poor and barbarous imitations of the human form; so that we may fairly infer, that the sculpture previous to this period could not have been very superior to the productions of Mexico, Otaheite, or the Sandwich Islands. In the popular story of the Maid of Corinth, related by Pliny, lib. 35. cap. 12. he says, Dibutades the Sicyonian potter, her father, first invented a method of taking likenesses, the process of which is described as follows: "His daughter being in love with a young man who was going to a foreign country, she circumscribed the shadow of his face with lines upon the wall by lamplight; her father took the impression in clay, and baked it in the fire with his vases." It seems, therefore, that as this was the first invention of portraits in clay, and as this portrait was only the relief impressed from a line scratched on the wall, that it must have been the very first stage of basso-relievo. Pliny proceeding says, that Dibutades made another addition to basso-relievo, by ornamenting the lowest row of rounded tiles, used to terminate roofs, with mask faces. These may be considered as two inventions, which distinguished the Sicyonian school. Pliny does not say at what time Dibutades lived, but he mentions him before Demaratus the father of Tarquinius Priscus, who must have been 630 years before Christ.

Independently of what may be deduced from these quotations, concerning the progress of basso-relievo in Greece, examples in this branch of sculpture exist in marble and bronze, which, with the aid of coins and gems, if properly arranged,

would form a complete chronological series from the introduction of letters in Greece. As the most ancient subjects to be chiefly selected are those which bear inscriptions, this arrangement would necessarily follow: the inscriptions of Cadmean letters first, the Boustrophedon manner of writing next, and the more modern as circumstances point out their propriety. This method would be found perfectly agreeable to the progress of science discernible in the works themselves, as well as the perfection of execution; and thus the antiquarian or the artist having insured an accumulation of testimony, would be in little danger of mistake. A passage in Pausanias, the first *Ellices*, or 5th book, shews the propriety of this method: he says, the cedar chest in which Cypselus was preserved by his mother (about 669 years before Christ), was dedicated by his posterity in Olympia. This chest is described as being covered with basso-relievo of allegorical and heroic subjects, explained by Boustrophedon writing, which the author describes as very old and difficult to read.

The earliest Greek sculpture which has come down to us is equal in the proportion of the figures to the Egyptian, and superior in the drawing of the body and limbs. Vitruvius informs us, that as the height of the human figure was six times the length of the foot, that was made the rule for the Doric column. (Book iv.) Thus we see the Greeks had been in the habit of measuring the human figure by its own parts, previous to the establishment of architectural proportions: and we find very tolerable general forms of the muscles and bones most commonly seen in the living body, which those early Greeks copied by close attention to the naked figures they constantly saw before them, without the aid of anatomical system; for Pliny (lib. xxix. c. 1.) says, the art of medicine remained in the darkest night from the siege of Troy to the time of Hippocrates. A few examples from the many existing will shew the progress of sculpture in basso-relievo, from the introduction of letters in Greece to the time of Phidias: these shall be set down according to their apparent antiquity, and followed by general observations.

In Winkelmann's "*Monumenti inediti*," plate 3. is a print from a scarabæus of Jupiter in his ear, holding the thunder with one hand, and trident with the other. This has the appearance of great antiquity in design and character, and perhaps is the oldest work cited in this article. The next is a patera of bronze in the British Museum, on which is carved Minerva subduing Hercules, or wisdom prevailing over strength. The next is an engraving of five of the seven chiefs who besieged Thebes. The last is Hercules bearing away the tripod from Apollo, which, by the improved style of drawing, seems to approach the time of Phidias. The first observation that occurs in this part of the subject is, that antiquarians have fallen into a considerable mistake in pronouncing many early works to be Etruscan, which later discoveries have almost certified to be Greek. The Grecian subjects cut on gems, the backs of which were formed into scarabæi like the Egyptian seals, have been positively called Etruscan by Winkelmann; notwithstanding that the style of the figures is early Greek, the subjects are Greek, and the letters upon them are Greek: besides which, Mr. Hawkins, a late accurate and highly-qualified traveller, has brought a Cornelian scarabæus found in that country to England, which has a Mercury engraved on it in that early style called Etruscan. How many more of these might travellers, if they sought for them, find in that country? And is it not likely that the Roman lords of the world would bring into their own country as many curious Greek gems as statues, when a dozen of the former may be conveyed in the palm

palm of a man's hand, whereas vast operations are necessary to transport only one marble or bronze statue? These arguments alone are sufficient to account for the gems of this description which have been found in Italy; besides some which may have been wrought in that country by Greek colonists, or the scholars of Greeks. A crowd of evidence might be adduced in this place to shew, that the vases formerly called Etruscan have been found in great abundance in Greece. Mr. Stuart and Mr. Parris brought many fragments of them from Athens, which are lodged in the British Museum; Mr. Graves brought several entire and beautiful painted vases from Greece, some of which were afterwards in the possession of Sir William Hamilton: and to these might be added many other testimonies and collections on this part of the subject.

One error more should be refuted before we proceed: Winkelmann (vol. i. lib. 3. c. 4.), in his history of the art, asserts, that "the Etruscans gave their Fauns horses' tails; whereas the Greeks represented Fauns and Satyrs with short tails like goats." The head-piece (p. 23. chap. 3. vol. ii.) of "Stuart's Athens," is a sufficient answer: it is a bas-relief of a Bacchanalian dance, in which two Satyrs have horses' tails. It was found in the ruins of the theatre of Bacchus, is of the style commonly called Etruscan; but, in fact, according to the time when this theatre was built (nearly 500 years before Christ), it is of the style of sculpture which prevailed in Greece immediately prior to the time of Phidias.

The general remarks on these works, during the period of about 550 years from the time of Cadmus to the time of Phidias, shall be confined to the three following: the manner of representing the gods; the manner of drawing the human figure and its actions; and, lastly, some observations on the draperies and utensils.

From the two proofs adduced that Grecian sculpture has been called Etruscan from the want of sufficient knowledge of the subject, and to which other proofs equally certain might be added (for instance, that all the early Greek coins are of the same style with that called Etruscan), it will seem to be a safe conclusion, that all ancient sculpture representing Greek subjects, should be considered as the work of Greeks, their colonists, or scholars, excepting in such cases as there is sufficient reason to believe the contrary. — Conformably to this regulation, the following observations may be offered on Greek sculpture preceding the time of Phidias. As the ancients represented their divinities in human forms, in the early times those forms were gross and imperfect, their aim being only to copy human nature; thus, in the gem above cited, of Jupiter with the thunder and trident, in Winkelmann's "Monumenti medii," pl. 3. his body and limbs are formed of few parts, gross and inelegant, his face is beardless, and his hair is thick and matted. Nearly the same may be said of the Hercules on the bronze patera in the British Museum, above mentioned; a figure of Neptune on the oldest coins of Pæstum; and the other monuments of the same ages, which represent Jupiter, Neptune, Mercury, and Hercules, by such figures as they employed to represent common men, equally devoid of beauty and character. The face of Minerva is not more delicate than that of Hercules, nor do his limbs appear more robust than those of Apollo. The gods were only known by their symbols: Jupiter by his thunder, Neptune by his trident, Mercury by his caduceus, Minerva by her helmet and ægis, &c. The gem of Jupiter with the thunder and trident above mentioned, which has also a four-footed animal under his car, perhaps a horse, agrees with Orpheus's hymn to that god, in which

earth and sea are said to be his; in this respect agreeable to the most ancient religion, and an argument of the high antiquity of the workmanship.

Concerning the manner of drawing the figure, it has been judiciously observed by the authors of the French Encyclopædie, "that the Greeks began where the Egyptians left off;" and some of the best (not perhaps the very best) of the Egyptian figures, are nearly fac-similes of the beginnings of Grecian art. However, improvements were soon made; they began to distinguish between muscle and bone, and the surface of the body and limbs were carefully marked with their greater subdivisions; the mastoid muscles and gullet marked the neck, the collar-bones were marked by nearly straight ridges, the edges of the ribs by an high arch, the abdomen by a double row of three nearly-square muscles on each side of the linea alba, and the division of the trunk from the limbs is strongly indicated by the edge of the pelvis; the shoulder is rounded, the biceps of the arm defined, the elbow expressed; a gentle indentation down the back of the lower arm shewed the situation of the ulna, the arm tapered downwards with a graceful swell for the muscles, and flatness for the part composed of bones and tendons; the insides of the thighs were flattened in the progress of the sartorius muscles, the lower tubercle of the thigh-bone was shewn immediately above the knee, which was expressed by the form of the patella; the inside of the shin was strongly expressed, as were the calves of the legs; the ankles were neat and small, rounded at the bottom; the feet and hands partook more of the forms of nature than the Egyptian, and the fingers and toes were made more neat, distinct, and various in the outline; on the back, the blade bones were marked as being little disguised by flesh, and the glutæi as small and firm. Upon the whole, they are men in an early state of society, whose hard and constant exercise in leaping, running, feats of dexterity in war and hunting, has made the covering of their bones tendinous and elastic, tapered their limbs, and whose quick and strong digestion has kept the loins narrow and the abdomen flat, whilst a free and powerful respiration expanded and raised the chest. The first essays of sculpture in the round figure, required that the arms should be attached to the body, and the legs joined together, for support, and to prevent the unskilful artist from breaking his work: but this restraint did not extend to bas-relief, in the same early composition of this kind; in which you see such simple positions as approach to formality. There are also figures in violent actions; as dancing satyrs, groups contending, and such exertions as shew the figure with sprawling, ungainly, and extravagant appearances; for hitherto the indications of grace were as small as those of beauty.

The draperies in the early bas-reliefs are thin, shewing the forms of the body and limbs; the folds regular, small, and distinct, consisting chiefly of perpendiculars and zig-zags. Some of the head-dresses consist of small curls, very like the fashions of barbarous nations described and drawn by modern travellers; and in the bronze patera in the British Museum above mentioned, the club of Hercules is ornamented with spiral dates, like one brought by captain Cook from the Sandwich islands.

The bas-relief of Hercules bearing the tripod from Apollo, mentioned above, seems to be nearer the time of Phidias than any of the other examples; not only from the superior elegance of the design, but likewise from its being in style very similar to the Bacchanalian dance found in the temple of Minerva at Athens. This subject of Hercules bearing the tripod from Apollo, is described by Pausanias

in the temple of Apollo at Delphos. It has been frequently repeated by the ancients in bas-reliefs and gems. A bas-relief of this subject, brought from Greece, was preserved in the Museo Nani at Venice; besides two others in the Albani collection. Thus we ascertain this to be a Grecian work, although in a style which has been supposed Etruscan; and by the likeness of its manner to the Bacchanalian dance above mentioned, its age may be nearly ascertained.

Our subject now presents the most important and perfect period in the art of sculpture, beginning with the great works executed by Phidias and under his direction, during the administration of Pericles. Greece enjoyed physical advantages, as well as moral and political institutions, peculiarly adapted to give the arts of design that perfection which could not be looked for in other countries. The climate was temperate, warm, and genial, which, to penetrating and elevated genius, added beautiful persons in its inhabitants; their games and exercises gave vigour and perfection to their forms; which initiated and familiarized the spectator with all the appearance of beauty in the human figure, in the different states of exertion or repose, whether naked or clothed. The practice of the arts of design was the peculiar privilege of those who possessed the greatest natural advantages, and were the best instructed; and in the person of the artist, as well as the subject represented, were frequently united the philosopher, the lawgiver, and the heroic defender of his country. Such were the studies for the artists, and such were the men who practised the art. The stores of theological and metaphysical knowledge had been laid in from Egypt and the East; science had accumulated; and commerce, cultivation, and patriotism, supplied the means of raising those monuments which were to be the admiration and study of all future ages.

These were the times and circumstances in which Phidias was employed by Pericles to adorn Athens with architecture and sculpture, with the assistance of the architects Calliades and Ictinus, who worked under his direction. Under these illustrious men, the Propylæum, the Temple of Minerva or the Parthenon, in the citadel, and the Temple of Theseus in Athens, were erected. The decorations of sculpture in these buildings are the most perfect specimens of art; which we must apply ourselves to with the utmost diligence to understand, if we would entertain hopes of producing any thing excellent in the same kind. The basso-relievos which fill the friezes which go round the pronaos, cell, and porticus, of the Parthenon, represent the panathenæic procession in honour of Minerva; which consists of a numerous company on horseback, victors in chariots, men leading oxen to sacrifice, tray-bearers, chorusses of virgins, some bearing candlesticks and some baskets, with their assistants and attendants. The sacred veil is produced and examined, the hierophantes explain the mysteries, and the gods themselves are seated, beholding, directing, and approving the whole. The alto-relievos in the metopes are the contests of the Lapithæ and the Centaurs. The alto-relievos in the tympanums of the east and west ends, are, alas! no more; war has deprived us of them. That of the east end was a miracle of art, from the remaining fragments (see Stuart's Athens, vol. ii.); and such it appeared to Sir G. Wheeler, who had the happiness to see it entire. However, we know by Sir George's description and drawing, that the subject of the east end was the birth of Minerva, or rather Minerva introduced by Jupiter to the gods; that on the west end, the contest of Minerva and Neptune for the patronage of Athens. As these subjects are of the highest kind the mind can conceive, so they are the noblest the hand can execute: they are theo-

logical and moral, as they represent the gods, their operations in the government of the universe, and providence in the disposition of human affairs; the heroes are exerted in the cause of justice, and the destruction of monsters.

Mr. Fuseli, the able and learned professor of painting in the Royal Academy of London, has judiciously applied Aristotle's division of poetry to the arts of design; and he considers the greater productions, as either epic, dramatic, or historic. According to these classes, the sculpture in each tympanum was entirely epic, as the gods only were represented in them engaged in single acts; the groups in the metopes are dramatic, because they represent a series of actions; and the frieze which goes round the temple is epic, inasmuch as the gods are preading; and are perhaps also historic, as particular persons and events may be represented in the procession. In the Temple of Theseus, the alto-relievos formerly in the pediments are gone entirely; nor do we know even what the subjects were. In the frieze round the pronaos is the battle of Marathon, in which the apparition of Theseus calls great stones on the Persians; Jupiter, Juno, and Minerva, Neptune, Apollo, and Diana, sit, behold, and determine the victory, the trophy of which is raised by the Athenians. The battle of the Lapithæ and Centaurs is in the frieze of the porticus: the metopes are filled with the labours of Theseus and Hercules.

The execution of these works is equal to the conception; the sentiment is elevated and fit, the composition is noble, full, and various; the gods are sublime and beautiful, their positions present dignity and repose; the heroes are vigorous and active, and an admirable simplicity reigns through the whole; whether you are roused by the terrific engagement of a Centaur and a Lapithæ, or captivated by the modesty of the virgin chorusses. In the battles, the figure is shewn in those classic curves and varied movements, those uncommon but advantageous situations, which equally excite surprize and admiration; every part is intelligible; they occupy such spaces of the ground as leave sufficient blank to render the outline distinct; and their quantities are so distributed, that one part is not bare while another is crowded: the lines themselves also become an ornament. The stories are told by one plan or ground of figures; and, like the principal characters in the tragedies of Æschylus, Euripides, and Sophocles, their effect is weakened by no under-plot of inferior heroes. The drawing of the figures is of the finest style, the outline and forms are chosen, the greater parts boldly expressed, the lesser parts delicately indicated, but not more than necessary. The heads fine, the drapery rich in folds, but perfectly natural; some of the remaining hands and feet of the most perfect beauty; and the horses may be described in the words Sir George Wheeler used to express his opinion of those he saw in the eastern tympanum of the Parthenon: "The horses are made with such great art, that the sculptor seems to have outdone himself, by giving them a more than seeming life; such a vigour is expressed in their prancing and stamping, natural to generous horses." The edges of the figures have been kept square in the working, to give the bolder effect to the relief; which was not high in the procession round the frieze under the portico of the Parthenon, in order that the sculpture might not overpower the architectural members. The sculpture in the two pediments of the Parthenon, the metopes in that temple and the temple of Theseus, as well as that round the frieze of the latter temple under the portico, are in alto-relievo. This Phidias discovered; it is called *torcuticæ*, rounded, by Pliny (lib. 34. cap. 8.); and he says, Polycleetus "so taught *torcuticæ*, alto-relievo, rounded work,

work, as Phidias had invented it:—*et toreuticen sic erudisse, ut Phidias aperuisset.*”

Besides the basso-relievos above mentioned, several others in Athens are of the highest beauty: the figures on the Temple of the Winds; the story of Bacchus and the Tyrrhenian mariners transformed into dolphins, on the Choragic Monument of Lykierates (Stuart's Athens, vol. i.), raised in the time of Alexander the Great; and two alti-relievos of the battle of the Athenians and Amazons, with another battle, subject unknown. (See the last two plates, vol. ii. of Stuart's Athens.)

Before we quit the subject of basso-relievo among the Greeks, it is proper to observe, that foliage ornaments in basso-relievo seem to have been introduced in Ionia about the same time with the Ionic capital; in the reign of Alexander the Great. (See the capital of an Ionic pilaster enriched with foliage, in the ruins of the temple of Apollo Didymæus, tail-piece, p. 55. Rivett's Ionia.) These inventions are two characteristics of the Ionian school.

Soon after this period, the most eminent Grecian sculptors and architects were almost entirely engaged in decorating the capital of their Roman conquerors. Most of their public works at home were inferior in beauty and spirit, in proportion as the intention was debased, which was chiefly that of paying fervile compliments to their masters; and the buildings raised, with a very few exceptions, were distinguished by a colonial inferiority from those of Rome, which the genius of Greece, and the spoils of the world, rendered the most magnificent of the times.

We may begin the observations on the basso-relievos executed or existing in Italy, by some notice of those cut in the rock. In the garden of the Capuchins' convent at Palazzuolo, on the lake of Albano, is a tomb; and in the tufa beneath, on the side of the rock, are carved the fasces, the curule seat, the diadem, and the sceptre. M. D'Hankerville believes this to have been the tomb of Tarquin the Elder; because he received these regalia from the Etruscan states, and because the tomb stands on the estate which belonged to him. There are other basso-relievos cut in the tufa, representing the combats of lions and gladiators, with other apparently domestic subjects, on the sides of a tomb at Corneto, the ancient Tarquinium: and although these works may be considered as Etruscan, yet there are reasons for thinking they are of Grecian origin; for Pliny (lib. 35. c. 12.) says, “that Demaratus, the father of Tarquin the Elder, in Hetruria, who was afterwards king of Rome, flying from Corinth, was accompanied by the modellers (*sculptores*) Euchira and Eugrammus, by whom modelling was brought into Italy.” There are, indeed, works known to be Etruscan, in the gallery of Florence; among which are many square cinerary urns of terra cotta: some of them bear basso-relievos of Greek subjects, and these are much the best; the rest are of an execution and manufactory equally ordinary. A terra cotta frieze of small figures, seven different subjects, was found some years since at Velletri, and preserved in the Borgian Museum. This seemed to be of the oldest Etruscan style: but still, as antiquarians have believed the stories to be Greek, and the frieze itself to be copied from a Greek original, so far this likewise must be considered as a production of the Grecian school. There is a print from one of these subjects, representing two women in a car drawn by two winged horses; the first head-piece, vol. iii. of Winkelmann's History of the Arts of Design, Fea's edition.

The taste for carved or chased plate of gold and silver was introduced at Rome, by the immense quantity which Lucius Scipio brought in triumph from the spoils of Asia, con-

sisting of 1,400 pounds weight of chased silver, and 100,000 pounds of gold vases, about 150 years before Christ. Pliny describes the fickleness of the Romans afterwards in works of this kind. “The vase of silver varies, by the wonderful inconsistency of the human disposition, not approving long the production of any workshop: now we seek the Furiian, now the Clodian, now the Gratian, now basso-relievo sharply cut, and now pictures expressed in lines.”

Modelling in stucco, called *plasticum* by Pliny, was practised under the first emperors, with extraordinary beauty, freedom, and slight of execution; as may be seen in the ornaments of the bath of purification at the temple of Isis at Pompeia, and the baths of Livia in the palace of the Cæsars at Rome.

It may be proper to enumerate some of the finest detached basso-relievos in the Roman collections, previous to those existing in the ancient buildings. In the Villa Borghese is one of young women in fine drapery, holding each other by the hand, and dancing. The figures are almost round; it is distinguished by beauty and simplicity. The sleeping Endymion of the Capitol; the sentiment of which is perfect, the figure elegant, and the execution bold: the Perseus delivering Andromeda from the rock; likewise in the Capitol: the large fragment of Antinous, in the Villa Albani: to which may be added, a most beautiful frieze on one side of the cortile of the palace Santa Croce, of Neptune and Amphitrite, sea-nymphs, tritons, and marine animals; and another beautiful frieze in the palace Della Valle, of victory sacrificing bulls to Mithras. Some others will be noticed under particular heads.

The alto-relievo of Auge and Telephus, mentioned with so much rapture by Winkelmann and some of his followers (see the Monumenti inediti, plate 72.), will only be noticed here to expose an hypercriticism. It is highly extolled for having three plans of objects in proportionate gradations of relief: it is self-evident that objects placed one beyond the other on a ground, must have different gradations of projection; but as this work has nothing else to recommend it particularly, either in character, sentiment, or composition, what has been said is sufficient to shew, that an indifferent work may become the object of admiration, by the magic of technical jargon, where sentiment, expression, a beautiful design, composition, harmony of parts, and all those particulars which can alone constitute excellence, are wanting.

Of the basso-relievos executed whilst the arts still retained some perfection under the Roman emperors, no specimens are remaining of those compositions of figures which adorned the pediments of buildings. A fragment of the frieze on the Temple of Minerva in Rome, near the Capitol, is still in tolerable condition; there are several prints of it in the “*Admiranda Romanorum.*” There are likewise in the different collections, detached specimens and fragments of friezes, pannels, and dies of pedestals. But the greatest number of basso-relievos in their original places, is on the triumphal arches and columns; and the greatest profusion of subjects is to be found on the sarcophagi. We shall pass the more hastily over these, because we have already noticed whatever is most excellent in this department of sculpture, in the ruins of Athens. The following triumphal arches are enriched with basso-relievo: those of Augustus, at Suza and Rimini; that of Trajan, at Beneventum; and at Rome, those of Titus, Marcus Aurelius (the basso-relievos of which are preserved in the Capitol, although the arch is destroyed); that of Severus; the goldsmiths' arch; and that of Constantine. The noblest composition, perhaps, among them is the apotheosis of Paulina, from the arch of Aurelius. (See Bartoli's Triumphal Arches.) The arch of Constantine is remarkable

able for its sculpture, part of which was done in the reign of Trajan, and the rest under Constantine; some of the former as remarkable for its grandeur, beauty, and boldness, as the latter for its barbarity; shewing the miserable decay of the arts in the course of 240 years. The two battles, the figures in which are as large as life, forming friezes under the cornices of the impostes in the middle opening of the arch, are grand and animated compositions, in a noble style of sculpture (see plate 42. and the following, in the *Veteres Arcus Augustorum*). Two observations on the arch of Severus will shew, that sculpture had declined considerably from the best ages. The principal basso-relievos occupy very large squares, containing figures, animals, cities, forts, and great warlike machines, on different plans, irregularly distributed, without regard to perspective; and thus, when viewed at such a distance that the detail becomes indistinct, they present the appearance of rustic work irregularly rough, and disagreeable as mixed with regular and magnificent architecture: unlike the friezes in the temples of Athens, which, as they have only one plan of figures, each simply and beautifully conceived, when viewed at a distance in which the detail disappears, they present to the eye a composition of lines distinct and harmonious, forming an ornament. It is also to be observed, that the small figures in these great squares are so boldly relieved, that they interfere with and destroy the effect of the smaller architectural members near them.

The triumphal columns demand our particular attention, not only for their magnificent design, structure, and materials, but also for the immensity of basso-relievo which covers them. But here we may observe, that imperial grandeur, by the endeavour to outstep, falls short of real greatness; and that where too much is expected or intended, too little is the result. With respect to the very conception of the Trajan column, a doubt has been entertained, whether a tower might not have allowed of a more grand and simple design for the purpose of a stupendous structure, than a Tuscan column mounted on a Corinthian pedestal. But notwithstanding the doubts of some judicious and unprejudiced persons on this point, the column has been the wonder and delight of all beholders for 1600 years. The spiral basso-relievo, reaching from the bottom to the top of the shaft, represents Trajan's first and second expedition against the Dacians, and his victory over their king Decebalus. Vasi (in his *Itinerary of Rome*) says, "they count upon it upwards of 2,500 figures, without reckoning horses, elephants, arms, machines of war, and an infinity of other objects;" to which may be added the four eagles on the corners of the pedestal, bearing festoons of laurel, and the arms on the die of the pedestal, all of matterly, and the last mentioned of the most delicate and laborious execution. But here a defect must be noted, in justification of the first observation on this noble monument, that although the figures increase somewhat, both in size and projection, as they approach the top of the column, yet it is certainly true, that any person standing on the ground cannot see the objects distinctly above one-third of the height of the shaft, beyond which all is confusion. Does it not follow, that if figures of that size were intended to be seen, they should not have been raised above one-third of the column; and if they were intended to be seen at a greater distance, their *size* should have been proportionably increased? That this is an optical defect cannot be denied; yet critics have taken pains to make their readers believe, that every thing relating to perspective in this column was beyond the reach of most modern comprehension for excellence; when any person acquainted only with the very first principles of perspective, must perceive

no attention whatever has been given to linear perspectives from the top to the bottom of the column: such injudicious praise proves only the absurdity and ignorance of the eulogist. Certainly the ancient sculpture contains whatever is truly excellent and admirable in the art; but let us choose the objects which are really possessed of those qualities, always distinguishing between beauty and the want of it; and then we cannot bestow our praises too liberally, nor study with too much diligence those perfections we would imitate, or be thoroughly acquainted with. The Antonine column is covered with basso-relievo, representing the victories of Marcus Aurelius over the Marcomanni. The sculpture is inferior to that on the Trajan column; and figures, having more projection, deform the outline of the shaft at a near view. The Theodosian column at Constantinople, drawn by Gentil Bellini (see Montfaucon), induce us to believe that sculpture did not decline so hastily in the East as in Italy.

Marble sarcophagi do not seem to have been used in Rome much before the time of Crassus, whose wife Cecilia Metella was buried in one. The fronts and ends of these coffins, from that time for many ages afterwards, were decorated with figures. Some of the finest compositions of the ancients are to be found upon them, most probably copied from Greek originals, by Roman manufacturing statuaries; one of whom lived on the Appian way, and occupied an extent of two miles in his works, as has been supposed from the quantity of sculpture finished and unfinished found on the spot, as well as an inscription which confirms the fact. The sublimity of the subjects leads us to think, that some have derived their origin from Phidias, Polycletus, and other of the greatest masters; as it is scarcely possible such groups and such expression as we see in these bad copies, could at first have been produced by inferior artists. Among them are the stories of Prometheus, Medea, Phaëton, Orestes, Alceste, the anger of Achilles, Bacchus and Ariadne, the fall of the giants, the judgment of Paris, &c. &c. These continued to be repeated till after the time of Constantine, when subjects from the Old and New Testament succeeded; but these were so barbarous that they merit no farther notice at present; and indeed the removal of the seat of empire to Constantinople had so despoiled Rome of riches and ability, that little effort could be expected in the West, and the little that was left became the successive prey to the Northern invaders, and the unavoidable destruction of time, for the following six centuries. Bas-reliefs of the eighth century, round the capitals of columns, representing Charlemagne and other figures, are in the Museum of French Monuments at Paris. There is also a bas-relief of Samson killing the lion, on a capital in the crypt of St. Peter's church, Oxford, done in the time of Alfred. Like all the works of these ages, they are barbarous and unmeaning.

In 1063 the Pisans began to build their cathedral, the old bronze gate of which contains a series of subjects from scripture in bas-relief; but so rude and gross, that they must be considered as the very beginnings of art. There is a basso-relievo of the acts of Abraham forming capitals to a group of columns, in the west door of the cathedral of Carrara, carved between 1100 and 1200, which is rather more detailed, though the figures are gross and disproportioned, not being above five heads high. Similar specimens may be seen of this age in different countries of Europe, from the first feeble efforts to revive sculpture. In such attempts as have been just mentioned, little improvement was made till towards the year 1230, when Nicolo Pisano having diligently studied some antique basso-relievos on sarcophagi at Pisa, was employed in carving similar ornaments of sacred subjects, in several

several cathedrals building at that time in different parts of Italy. He was assisted by his son John, and among other pupils, by two who seem to have been particularly esteemed, Arnolfo and Lapo. Besides being architect to several cathedrals in Italy, Nicolo, with the assistance of his pupils, carved some basso-relievos in marble; which were works of wonderful merit in that age, and would certainly deserve considerable admiration and respect in any other time or country, for sublimity, sentiment, truth, and beauty of execution. The following deserve particular notice: Stories from the Life of our Saviour, on the pulpit and baptistery of Pisa; similar subjects on the pulpits of the Duomos of Siena and Pistoia. But the greatest and most estimable of these works is on the front of the cathedral of Orvieto. This front is one of the most splendid, both for materials and art, that the mind can conceive, or the resources of nature furnish. It is built of statuary marble, wrought with the nicest care, and ornamented with the most delicate labour; the bolder mouldings and smaller pillars are relieved by Mosaic tiles of the most splendid colours and designs; and magnificent Mosaic paintings of sacred subjects finish the decoration immediately under the cornice. The basement between the great and two side doors, from the height of six feet to that of twenty feet, is covered with subjects from the Bible in a great number of divisions representing all the principal facts, and concluding with the Resurrection, Judgment, and final destination of the good and wicked; the subjects are divided by running ornaments of vine, and other foliage, of uncommon delicacy and fancy. There is an alto-relievo by Nicolo, on the church of St. Martin at Lucca, of the Descent from the Cross, which is extremely pathetic and simple. The basso-relievos on the oldest bronze gate of the baptistery of Florence, by Andrea Ugolino of Pisa, after designs by Giotto, of the Life of St. John the Baptist, are simple and grand. Donatello, born in Florence 1393, executed bronze basso-relievos on the two pulpits of St. Lorenzo in that city: the principal subjects are the Crucifixion and Internment of our Saviour, in which the expression is admirable. Vellano of Padua, his scholar, made some fine basso-relievos of bronze in the church of St. Antony in that city. But the work of this description which obtained the highest reputation in that age, was the second bronze gate, executed by Lorenzo Ghiberti, his father, and other assistants, for the before-mentioned baptistery of St. John in Florence. On it, ten compartments are filled with subjects from the Old Testament, beginning with the Creation and ending with the meeting of Solomon and the Queen of Sheba; the spaces between the panels are adorned with foliage, heads, and beautiful figures of prophets and sibyls; the architrave is ornamented with festoons of flowers and birds, of so perfect an execution that they seem to be cast from nature: the whole is of gilt bronze. Vasari relates that Michael Angelo said, "It deserved to be the gate of Paradise." Certainly an admirable fancy, delicacy, expression, grace, and execution, are to be found in every part of it; but its general character is rendered trivial by the introduction of so many plans, so much landscape and architecture in perspective, with the affectation of picturesque effect in the chiaro scuro. But this fault must be palliated by the remembrance, that perspective was a new discovery to the moderns, wonderfully admired at the time: it had turned the brains of Paolo Uccello, a painter of great merit; and it is not to be wondered at, if Lorenzo Ghiberti, who had practised painting, should have fallen into the delusive hope of adding a new charm to sculpture, which in fact belongs to painting exclusively.—From this time little can be said in commendation of the practice of basso-relievo. Memory was substituted for imitation, fancy for nature; and the consequence was,

those various species of affectation which are called manners. The schools of John of Bologna, Algardi, Bernini, will justify this remark; and whoever takes the trouble to examine their productions in this department of sculpture will see, that art more than nature has been their object.—Within the last century a number of circumstances have combined to develop the principles of sculpture, and a considerable emulation has been excited to attain its real perfections. A prodigious number of ancient statues, groups, busts, and basso-relievos in marble and bronze, as well as pictures, have been discovered; these have been magnificently and judiciously arranged, not only in the public museums of Italy, but in private collections of the different countries of Europe. Such admirable works have excited universal curiosity and interest; the number of books on the subject have been increased by learned men and elegant critics; students have repaired in greater numbers than formerly from all parts to copy those works with great diligence; the number of contenders has produced emulation, each one endeavouring to distinguish himself above his competitors: thus they have laid up a large stock of ability for employment in their own countries, where taste for the arts of design has been gradually increasing; so that now there are sculptors in Italy, France, England, Germany, &c. who have produced basso-relievos of great merit, as well as other works of sculpture.

Winkelmann has said, "that Sculpture, like an elder sister, has introduced and led her younger sister, Painting, into the world:" this is elegantly said, and on that account is likely to obtain currency more than for the certainty of its truth. What additional value does one art acquire over the other by being older? Both arts are noble and virtuous pursuits; the fine productions of both afford intellectual and rational delight; and there is difficulty enough in the way to excellence in both, to exercise the utmost stretch of the most powerful geniuses who have engaged, or may engage, in the study of them. It should seem by Pliny's account, lib. 35, c. 3. and c. 12. that the beginning of painting and basso-relievo were alike; for the first advances towards basso-relievo were made by Dibutades's taking the impression of an outline. Ardicus the Corinthian, and Telephanes the Syeionian, made the first essays towards painting, before colour was used, by outline also.—But to leave this question of little moment, let us go to those considerations which are of real importance to the subject we are treating. It has already been shewn, that basso-relievo, from the earliest ages, was used as representative writing; and the right and only good purposes to which writing as well as speaking can be applied is to honor God, and to recommend and disseminate whatever is virtuous in public or private, and useful among men. Thus was basso-relievo employed in the best ages by the ancients, according to their several systems of theology, philosophy, and ethics: and thus only it should be employed; for when it is applied to other purposes, it is a deviation from the original intention, ceases to be useful, and must engage the artist in the representation of persons and things below that standard to which he should constantly aim. Phidias gave a perfection to his Jupiter which astonished all men, and induced them to believe he had been favoured with a revelation of the god, by the human representation of power, majesty, benignity, and wisdom. And we shall find that whatever appears admirable, perfect, or lovely, in the representations of the ancient deities or heroes, is some mental or bodily perfection. The Christian religion presents personages and subjects no less favourable to painting and sculpture than the ancient classics: angels and archangels should be as perfect in youth and beauty as the youthful divinities of Greece. The heroes of the Old Testament bear so striking a resemblance to those of Greece, that eminent moderns have mistaken

them for the same persons. Nothing can be found in the fages of Greece, more august or sublime than in the patriarchs or prophets: they were equally inhabitants of warm climates, favourable to the display of the human figure; and their cloathing and arms were nearly similar. Indeed it may be safely asserted, that the bas-relievs of the Last Judgment by Nicolo Pisani, the Crucifixion and Entombing of our Lord by Donatello, and some of the pannels in Ghiberti's gate, prove that the Bible presents subjects, and those almost innumerable, of greater interest, and as abundant in all the excellence of composition, as any to be found in the classical authors: such subjects are the proper decorations for churches and other public edifices of most importance to society, which should be perpetual schools of instruction.—After the choice of subject, the economy and manner of treating are next to be considered. And here several hints may be found in Aristotle's poetics, and in the conduct of the Greek tragedies, as useful for the composition of a basso-relievo as a poem; with this difference, a poem embraces a succession of times, but a basso-relievo one moment only: and where this rule has been trespassed, the same person has been introduced twice over. That one moment must represent an action, into which 10 more figures should be admitted than are necessary; because the increase of number is the distraction and loss of expression. The sentiment, the expression, and every part should be as elevated and advantageous as the nature of the subject will admit.—Concerning the execution, the basso-relievs of the Parthenon temple of Theseus, the others in the ruins of Athens, and a few more which are truly Greek, must be set up as the perfection of what has hitherto been done: the compositions are intelligible, because the figures are distinctly seen on the back-ground and not crowded one behind another; the drawing of the figures is from chosen examples, feelingly, forcibly, and faithfully copied; the pathos of the subject is not weakened by the introduction of building in perspective, or the affectation of chiaro scuro, which attempts to introduce the distances of painting in basso-relievo. Agatharchus employed perspective in painting scenes, but Phidias and Polycleus knew that the form and expression of the human figure was the object of their sculpture.

Some very fine and extraordinary antique basso-relievs enrich the collections of England:—

The tomb-stone of Xanthippus, and a man curbing a horse, both about the time of Phidias, are in the collection of Charles Townley, esq.

The marquis of Lansdown has a Greek bas-relief of Chalcas, as large as life.

At Wilton House there is a fine example of the death of Meleager, and a small but curious Hercules and Ægle, a basso-relievo composed of mosaic, in natural colours, which is supposed to be the only one of the kind.

The celebrated Barberini vase, in the possession of the duke of Portland, is of dark blue glass, bearing figures in basso-relievo of white enamel or glass of admirable workmanship. (See Bellori Sepolchri Antichi, *Plate* 84.) Fragments of basso-relievs in similar materials have been found in the ruins of the Cæsars' palace in Rome, where they had been fixed in the walls.

John Hawkins, esq. the Grecian traveller, possesses a beautiful small bronze basso-relievo of Paris, Helen, and two Genii, which he brought with him from Greece.

Plate I. 1. Contains an Egyptian hieroglyphical sphinx. 2. An Hindoo bas-relief. 3. A Persian bas-relief. 4. Jupiter with the thunder and trident, a Greek gem of the oldest style.

Plate II. 1. Minerva subduing Hercules, from a very ancient Greek patera of bronze in the British museum. 2. Apollo and Hercules contending for the tripod.

Plate III. The tomb-stone of Xanthippus, father of Pericles.

Plate IV. 1. A capital of a column in the west door of the cathedral of Carra, representing part of the history of Abraham; a work of the twelfth century. 2. A beautiful Greek basso-relievo, near the time of Phidias, of Zethus and Amphion comforting their mother Antiope; from the Villa Albani.

Basso & Alto, in *Lace*. See *Alto*.

BASSOMPIERRE, FRANCIS DE, *Marshal*, in *Bisography*, was a descendant of a distinguished family in Lorraine, and born in 1570. Engaging betimes in military service, he rose to the office of colonel-general of the Swiss, and in 1622, to that of marshal of France. He was also employed in a diplomatic capacity to Spain, England, and Switzerland. In these employments he was distinguished by his talents and conduct, and particularly by his wit, noble air, politeness, and generosity. He spoke all the European languages, was an adept in gallantry, and much addicted to play. By his bons mots, which were sharp and satirical, he offended cardinal Richelieu: who caused him to be confined in the Bastile in 1631, where he continued for twelve years till the death of this minister. In this retreat he passed his time in reading and writing; and the historical works which he composed were the productions of his imprisonment. These are “Memoirs, containing the history of his life, and of the most remarkable occurrences at the court of France from 1598 to 1631,” 3 vols. 12mo.; “An Account of his Embassies,” 2 vols. 12mo.; and “Remarks on the History of Louis XIII. by Duplex,” 12mo. These works abound with curious particulars and strokes of satire. After his liberation he was restored to his rank of colonel of the Swiss, and was fixed upon as governor to the young king Louis XIV, but excused himself on account of his age and infirmities. Towards the close of his life he became very corpulent, and died of an apoplexy in 1646. Gen. Biog.

BASSOON, in *Music*, from *bas son*, Fr. low sound, in opposition to *hautbois*, to which it is the natural base. Like the hautbois, it is played with a reed, and is a continuation of the fagot downwards. It is composed of four different pieces or tubes, which when separated are bound together like a faggot; hence by the Italians called *fagotto*. It has three keys of communication to open and shut the ventages, which from the length of the instrument, are out of the reach of the fingers. It has a crook, or mouth-piece, to which the reed is fixed. (See *REED*.) The whole length of the instrument is eight feet; but reduced to four, by being doubled up like a trumpet for convenience in performance and carriage.

Its compass is three octaves,

from double AA in the base to a in the second space of the treble; of which the tones and semitones are as complete as on an organ, or any other keyed instrument. Every performer is not able to produce a lower sound than double BBB in the base, or a higher than G in the second space in the treble.

In the last age, Miller was the favourite performer on the bassoon in England at all public places; but we have at present Mr. Holmes, a superior performer, at least in point of tone, to any that we have ever heard elsewhere. A scale for this instrument will be found in the musical plates.

The two Bezozzis of Turin rendered these kindred instruments, the hautbois and bassoon, famous in Italy, during the middle of the last century. See *BEZOZZI*.

BASSORA,

BASSORA, **BALSORA**, or **BASRA**, in *Geography*, a famous city of Asia, in the Arabian Irak, situate on the western banks of the Shat al Arab, which is a navigable canal, formed by the junction of the Euphrates and Tigris. This canal is navigable for vessels of fifty tons to the Euphrates, and thence to the gulf of Persia, from which it is distant about 15 leagues north-west. This city was founded in the year 636 by order of Omar, the second caliph, to hinder the commerce that subsisted between the Indians and Persians, and to secure the command of the two rivers by which goods imported from India were conveyed into all parts of Asia. The first colony was composed of 800 Moslems; but the situation was so wisely chosen that it soon became a flourishing and populous capital, and a place of trade, scarcely inferior to Alexandria. The air, though excessively hot, is pure and healthy; the meadows are covered with palm-trees and cattle; and one of the adjacent vallies has been celebrated among the four paradises or gardens of Asia. Under the first caliphs, the jurisdiction of this Arabian colony extended over the southern provinces of Persia. The city has been sanctified by the tombs of the companions and martyrs; and the vessels of Europe still frequent the port of Bassora as a convenient station and passage for the Indian trade. Merchants of Arabia, Turkey, Armenia, Greece, Jews, and Indians reside here; the English and Dutch have their consuls, and their ships come from India loaded with various kinds of merchandize. Those from Bengal, which arrive from the month of March to June, bring white silens, silk, muslins, baitard-saffron, sandal, and other woods, benzoin, varnish, rice, lead, European tin and iron. From the coast of Coromandel they bring thicker cloths, white or blue; which are used by the Arabians for their garments. From the coast of Malabar they bring cardamom seeds, pepper, &c. From Surat they receive all kinds of gold and silver stuffs, turbans, blue cloths, indigo, and steel; of which the Persians are the chief purchasers for the manufacture of their fabres. The principal merchandizes of the Dutch are spices and coffee from Java. Some Arabians bring slaves, and others bring pearls from Bahrein, and coffee from Mocha. The neighbouring countries also furnish merchandize for exchange; of which the most considerable are the ancient copper of Persia in small cakes, drugs of various kinds, grain when it is allowed to be exported, dates, wine, and dried fruits. The merchandize is sold for ready money, and passes through the hands of the Greeks, Jews, and Armenians. The Banians are employed in changing the coin current at Bassora for that which is of higher value in India. The abbé Raynal values the merchandize annually brought to Indri at 525,000l.; of which the English furnish 175,000l. the Dutch 87,500l. and the Moors, Banians, Armenians, and Arabs furnish the remainder.

Bassora has been subject to the Turks ever since the year 1668; and, like other cities tributary to that dominion, is governed by a *cadi* appointed by the prince of Bassora. But it may now be regarded as belonging to an independent Arabian prince, who pays dubious homage to the Ottoman Porte. This prince allows full liberty to all nations to come and trade to his capital; and the police of the city is so well maintained, that a person may pass safely through the streets at any time of the night. The prince derives his chief revenue from the exchange of money for the horses and camels that are sold here, and also from his plantation of palm-trees, which is said to be 90 miles in length. The horses that are bred in its vicinity are in great repute, and are sold at a high price. The income of the prince from the several articles of money, horses, camels, and dates, is so great, that he

has a considerable surplus after discharging all the expences of his tribute and government. The opulence of Bassora is owing partly to the extensive commerce which is carried on by the intervention of this town between Asia and Europe, partly to its being a place whence letters may be dispatched into all parts of Europe, particularly England and Holland, by way of Damascus and Aleppo, for which purpose Arabs, who are very swift-footed, are employed; and partly to the resort of Persian caravans in their pilgrimages to Mecca, where they pay considerable duties to the government, and exchange many valuable commodities. The number of inhabitants is computed to be about 50,000; the majority being Arabs: the rest are principally Turks and Armenians. The latter are the merchants, and some of them are very respectable. As to the religion of Bassora, besides Mahometans, there are Syrian Jacobites and Nestorians, and monks from Europe; and also some modern Sabæans, whom they call disciples of St. John. The town is of great extent, and surrounded by a wall of clay, said to be twelve miles in circumference. The Bazar, or market-place, is about two miles long and well supplied. The buildings of this city are mostly constructed after the Turkish manner. The whole country about it is so low, that it is prevented from being inundated by a dyke or bank extending between three and four miles along the coast, and built of large square stones so well cemented together that the sea cannot affect it, though the sea runs strongly against it at the extremity of the Persian gulf. Bassora is 210 miles S. W. of Ispahan, and 600 S. E. of Aleppo. N. lat. 29° 45'. E. long. 47° 40'.

BASSOS, or **BAXOS**, *Cape*, lies in the Indian sea, on the east coast of Ajan in Africa, in N. lat. 4° 12'. E. long. 47° 7'.

BASSOS de Bambos, shoals in the Indian ocean, lying off the east coast of Zangubar in Africa, in S. lat. 5° E. long. 48° 8'.

BASSOS de Chaga, or shoals of Chaga, are situated in the Indian ocean, in S. lat. 6° 42'. E. long. 68° 20'.

BASSOS de India, shoals of India, are situated N. E. easterly from the cape of Good Hope, and are called in some charts Jews Rocks, between Madagafcar island on the east and the coast of Africa on the west, about Sofala. S. lat. 22° 30'. E. long. 40° 41'.

BASSOUES, a town of France, in the department of the Gers, and chief place of a canton in the district of Mirande, 5 leagues W. S. W. of Auch.

BASSOVIA, in *Botany*. Lin. gen. Schreb. n. 348. Aubl. 85. Juss. 419. Clafs and Order, *pentandria monogynia*. Gen. Char. *Cal.* perianth one-leaved, permanent, five-parted; parts ovate, acute. *Cor.* one-petalled; tube very short; border five-cleft, spreading; clefts ovate, acute, larger than the calyx. *Stam.* filaments five, inserted into the tube of the corolla, and opposite to its clefts; anthers ovate. *Pist.* germ ovate, sitting on a glandule; style short; stigma thickish, obtuse. *Per.* berry ovate, knobbed. *Seeds*, very numerous, kidney-shaped, girt with a membrane, swelling in pulp.

Ess. Char. *Cor.* five-cleft, spreading, with a very short tube; berry ovate, knobbed, with many seeds.

Species. *B. sylvatica*. Aubl. Guian. 217. t. 85. Stem herbaceous, three or four feet high, branched; leaves alternate, ovate, acute, smooth, entire, on a petiole about an inch long; the largest 10 inches long and 4½ broad; flowers in axillary corymbs, green, and very small. A native of Guiana, in wet forests, flowering and fruiting in June. Martyn's Miller's Dict.

BASSUEL, in *Geography*, a town of France, in the department of the Marne, and chief place of a canton in the district of Vitry la Françoise, 6 miles N. N. E. of Vitry.

BASSUEL, PETER, in *Biography*, born in Paris in 1706, was early initiated in the knowledge of surgery, by attending the hospitals and the lectures of the principal teachers there. In 1730 he was admitted to practice; and the academy of surgery being instituted the following year, he was nominated by the king one of the first members. In 1744, he was chosen demonstrator royal in therapeutics. He took part in the dispute on a question then much agitated, Whether the heart was shortened in its systole, or contraction, to expel the blood from the ventricles? But his opinion was formed, Haller says, from theory only. His dissertation on the subject was published in one of the medical journals of the time. He died June 4th 1757. Haller. Bib. Chir. Eloy. Dict. Hist.

BASSVIOL, in *Music*. See **BASE-VIOL**.

BASSUM, in *Geography*, a town of Germany, in the circle of Westphalia, in the county of Hoya, with a noble abbey; 16 miles west of Hoya.

BASSURE SAND, begins at Ambleteuse, a little to the south of St. John's, on the coast of France, close to the shore, and stretches out S.W. by S. and S.W. by W.

BAST ISLAND, is situated on the coast of Norway, 5 leagues N. W. by W. from the Sisters' island, which lies 4 leagues at W. by N. from Acker sound.

BASTA, GEORGE, Count, in *Biography*, an Epirote by descent, was born at La Rocca, a village near Tarentum; and devoting himself to the military profession, he was commander of an Epirote or Albanese regiment of horse, when the prince of Parma assumed the government of the Low Countries in 1579. Under this great general he perfected himself in the military art, and was preferred by him to the post of commissary-general of cavalry, and also employed in many important enterprises. The principal theatre on which his talents were exhibited, was the war in Transylvania and Hungary, where in 1601, he gained a signal victory over Sigismund Battori, and took the town of Clausenburg. Having completed the ruin of Battori, he granted him peace on condition of his renouncing all rights over Transylvania. However, the severities exercised by Basta against the protestants of that country did great injury to the cause of the emperor; and the Imperialists, under the count Belgioio, were defeated. Although Basta, in 1605, could not prevent the Turks from taking Strigonium or Gran, he made a judicious arrangement before Comerra, which hindered their further advances. Having made a peace, he soon after died in 1607. Basta was the author of two professional works that are much esteemed: the "Maestro di campo generale" (Quarter-master general), printed at Venice, in 1606; and "Governo della cavalleria leggiera" (Discipline of the Light Horse), Frankf. 1612. Gen. Dict.

BASTA, in *Ancient Geography*, a town of Italy, in Iapygia, on the eastern coast, at a small distance N. E. of the Salentine promontory.

BASTA, in *Geography*, a town of Egypt, 40 miles N. E. of Cairo, and 31 S. S. E. of Mansora.

BASTA, or *Bastora*, a place of trade on the coast of Africa, before which is a road with 20 to 23 fathoms of water, and tolerably good ground.

BASTA, in *Natural History*, a species of **SPONGIA**, found in the Indian sea, and called by Rumphius *bajla marina*, *lesla-lant*. It is somewhat rigid, blackish, with undulated divisions; stem round. Pallas. Found adhering to stones, and is about the thickness of a finger. Gmelin, &c.

BASTAGARII, in *Antiquity*, a college or company at Rome, who carried the fiscal species out of the provinces to Rome or Constantinople. The directors of these were

called *propositi bastagorum*. The word is derived from *bastago*, which properly imports the office of carriage or conveyance; from *bassus*, *portare*, to carry. The denomination *bastagarii* has also been given to those who carry the images of saints at processions. Du-Cange.

BASTAL, in *Geography*, the name of a romantic and fertile vale of Switzerland, lying in the direct road from Basle to Soleure, through the midst of the Jura mountains.

BASTAN, a town of Asiatic Turkey, in the province of Natolia, 30 miles S.W. of Amadia.

BASTARD, THOMAS, in *Biography*, a clergyman and poet of the sixteenth century, was born at Blandford in Dorsetshire, and educated at Winchester school; whence he was removed to New college Oxford, and chosen perpetual fellow in 1538: but indulging too much his talent for satire, he was expelled the college for a libel. He afterwards became chaplain to Thomas earl of Suffolk, lord-treasurer of England, and, by his interest, vicar of Bere-Regis, and rector of Hamer in his native county. He was a person of great natural endowments, and skilled in the learned languages, a celebrated poet, and, in his later years, an excellent preacher. Towards the close of his life, he was deranged and involved in debt; and being confined in prison at Dorchester, he died in an obscure and mean condition in 1618. He was thrice married: first, as he informs us in one of his epigrams, in his youth for love; again, in maturer age, for money; and a third time, in his old age, for a nurse. His poetical performances, which were admired in that age, were "Epigrams," and a Latin poem, entitled, "Magna Britannia," London 1605, 4to. He also published a collection of "Five Sermons;" and another of "Twelve Sermons," Lond. 1615, 4to. Biog. Brit.

BASTARD, in *Law*, a natural child, or one that is not only begotten, but born, out of lawful wedlock.

The word is of Saxon etymology, and is compounded of *bajz*, vile or ignoble, and *sturt*, or *stuart*, original.

According to the civil and canon laws, a child doth not remain bastard, if the parents afterwards intermarry; but it is an indispensable condition of legitimacy, according to our law, that it shall be born after lawful wedlock. In this respect our law is far superior to the Roman; because marriage being principally designed for ascertaining some person to whom the protection, maintenance, and education of the children should belong, this end is better answered by legitimating all issue born after wedlock than by legitimating all issue of the same parties, even born before wedlock, so as wedlock afterwards ensues; in proof of which, Blackstone alleges the following arguments.

1. Because great uncertainty will generally attend the evidence, that the issue was really begotten by the same man; whereas, by confining it to the birth, and not to the begetting, our law has rendered it perfectly certain, what child is legitimate, and who is to take care of the child. 2. Because the Roman law, by which a child may be continued a bastard, or made legitimate, at the option of the father and mother, by a marriage "ex post facto," opens a door to many frauds and partialities which our law prevents. 3. Because by those laws a man may remain a bastard till forty years of age, and then become legitimate by the subsequent marriage of his parents; and thus the main end of marriage, or the protection of infants, is totally frustrated. 4. Because this rule of the Roman law admits of no limitations as to the time or number of bastards so to be legitimated; but a dozen of them may, 20 years after their birth, by the subsequent marriage of their parents, be admitted to all the privileges of legitimate children. This is plainly a great discouragement to the matrimonial state; to which one principal inducement is usually not only the desire of having *children*, but also the desire of procreating lawful *heirs*.

Whereas

Whereas our constitutions guard against this indecency, and at the same time afford sufficient allowance to the frailties of human nature. If or if a child be begotten while the parents are single, and they will endeavour to make an early reparation for the offence by marrying within a few months after, our law is so indulgent as not to bastardize the child, if it be born, though not begotten, in lawful wedlock: for this is an accident that can happen but once, since all future children will be begotten, as well as born, within the rules of honour and of civil society. Upon reasons like these, Blackstone supposes the peers to have acted in the parliament of Mortor, when they refused to enact that children born before marriage should be esteemed legitimate. Stat. 20 Hen. III. c. 9. See the introduction to the great charter, edit. Oxon. 1759, sub anno 1253.

Hence it appears, that all children born before matrimony are bastards by our law. But if a man marries a woman grossly big with child by another, and within three days after, she is delivered, the child is no bastard. 1 Danv. Abridg. 729. If a child is born within a day after marriage between parties of full age, if there be no apparent impossibility that the husband should be the father of it, the child is no bastard, but supposed to be the child of the husband. 1 Roll. Abr. 358. Moreover, all children born so long after the death of the husband, that by the usual course of gestation they could not be begotten by him, are bastards. But this being a matter of some uncertainty, the law is not exact as to a few days. It appears, upon the whole, that what is commonly considered as the usual period is 40 weeks or 280 days; but if the child be born some time after, it only affords presumption, not proof, of illegitimacy. This uncertainty of the period of gestation has given occasion to a proceeding at common law, where a widow is suspected to feign herself with child, in order to produce a supposititious heir to the estate; an attempt which the rigour of the Gothic constitutions esteemed equivalent to the most atrocious theft, and therefore punished with death. In this case, with us, the heir presumptive may have a writ "de ventre inspiciendo," to examine whether she be with child or not; and if she be, to keep her under proper restraint till delivered; which is entirely conformable to the practice of the civil law: but if the widow be, upon due examination, found not pregnant, the presumptive heir shall be admitted to the inheritance, though liable to lose it again on the birth of a child within forty weeks from the death of a husband. But if a man dies, and his widow soon after marries again, and a child is born within such a time, as that by the course of nature it might have been the child of either husband; in this case, he is said to be more than ordinarily legitimate: for he may, when he arrives to years of discretion, choose which of the fathers he pleases. (Co. Litt. 8.) To prevent this, among other inconveniences, the civil law ordained that no widow should marry "infra annum luctus;" a rule which obtained so early as the reign of Augustus, if not of Romulus: and the same constitution was probably transmitted to our early ancestors from the Romans, during their stay in this island; for we find it established under the Saxon and Danish governments. L. L. Ethelr. A.D. 1008. L. L. Canut. c. 71.

As bastards may be born before the coverture or marriage state is begun, or after it is determined, so also children born during wedlock may in some circumstances be bastards. As if the husband be out of the kingdom of England, or as the law somewhat loosely phrases it, "extra quatuor maria," for above nine months, so that no access to his wife can be presumed, her issue during that period shall be bastards. (Co. Litt. 244.) But, generally, during the coverture access of the husband shall be presumed, unless the contrary be shewn: (Salk. 123. 3 P. Wms. 276. Stra. 295.) which is

such a negative as can only be proved by shewing him to be elsewhere; for the general rule is, "presumitur pro legitimatone." There are some determinations by which it appears, that the child of a married woman may be proved a bastard by other circumstantial evidence besides that of the husband's non-access. 4 Term. Rep. 251. 356.

In a divorce "a merita et thoro," if the wife breeds children, they are bastards: for the law will presume the husband and wife conformable to the sentence of separation, unless access be proved; but in a voluntary separation by agreement, the law will suppose access unless the negative be shewn. (Salk. 123.) So also if there be an apparent impossibility of procreation on the part of the husband, as if he be only eight years old, or the like, the issue of the wife shall be bastard. (Co. Litt. 244.) Likewise, in case of divorce in the spiritual court, "a vinculo matrimonii," all the issue born during the coverture are bastards; because such divorce is always upon some cause that rendered the marriage unlawful and null from the beginning. Co. Litt. 235.

If a man or woman marry a second wife or husband, the first, being living, and have issue by such second wife or husband, the issue is a bastard. (Bott. 397. pl. 521.) Before the statute 2 & 3 Ed. VI. c. 21. one was adjudged a bastard "quia filius sacerdotis."

If a man hath issue, a son, by a woman before marriage, and afterwards marries the same woman, and hath issue, a second son, born after the marriage; the first of these is termed in law a "bastard eigné," and the second a "mulier," or "mulier puifné." By the common law, a "bastard eigné" is as incapable of inheriting as if the father and mother had never married. However, there is one case in which his issue was let into the succession, and that was by the consent of the lord and person legitimate; as if upon the death of the father the "bastard eigné" enters, and the "mulier" during his whole life never disturbs him, he cannot upon the death of the "bastard eigné" enter upon his issue. In this case the "mulier puifné," and all other heirs, are totally barred of their right. This indulgence, however, is shewn to no other kind of bastard; for if the mother was never married to the father, such bastard could have no colourable title at all. (Lit. sect. 399, 400. Co. Litt. 245.) To exclude the "mulier" from the inheritance, there must not only be an uninterrupted possession of the "bastard eigné" during his life, but a descent to his issue. Co. Litt. 244. 1 Rol. Abr. 624.

The duty of parents to their bastard children, by our law, is principally that of maintenance. The method in which the English law provides maintenance for illegitimate children is as follows. When a woman is delivered, or declares herself with child, of a bastard, and will by oath before a justice of peace charge any person as having got her with child, the justice shall cause such person to be apprehended, and commit him till he gives security, either to maintain the child, or appear at the next quarter sessions to dispute and try the fact. But if the woman dies or is married before delivery, or miscarries, or proves not to have been with child, the person shall be discharged; otherwise, the sessions, or two justices out of sessions, upon original application to them, may make an order for the keeping of the bastard, by charging the mother or the reputed father with the payment of money or other sustentation for that purpose; and if the party disobey such order, he or she may be committed to gaol, until they give security to perform it, or to appear at the sessions. The justices may commit the mother of a bastard, likely to become chargeable, to the house of correction for a year; or, for a second offence, till she give security for her good behaviour. And if such putative father, or lewd mother, run away from the parish, the

overseers, by direction of two justice may take the rent of goods, and chattels, in order to bring up the said bastard child. Yet such is the severity of our laws, that no woman can be lawfully expelled concerning the father of her child, till she hath first delivered. Stat. 1 Edw. c. 2. 7 Jac. I. c. 15. 2 Car. I. c. 2. 13 & 14 Car. II. c. 12. 10 Geo. II. c. 31.

As to the issue of a bastard, there are very few; but if only such as be aquired, and are inherit nothing, being regarded as the son of a body; and sometimes called "nullius filius," sometimes "nulli pupilli." Fortesc. de J. L. c. 40. Yet he may gain fortune by reputation, though he has none by inheritance. Co. Litt. 3. Where a bastard is limited to the eldest son of such wife her legitimate or illegitimate, and she hath issue, a bastard shall take this remainder; because he acquires the denomination of her issue by being born of her body. Noy. 55. All other children have their primary settlement in their father's parish; but a bastard in the parish where born, if he hath no father. Salk. 127. However, in case of fraud, as if a woman be sent either by order of justices, or comes to beg as a vagrant, to a parish to which she does not belong, and gives her bastard there, the bastard shall, in the first case, be settled in the parish from which she was illegally removed (Salk. 127); or, in the latter case, in the mother's own parish, if the mother be apprehended for her vagrancy. 17 Geo. II. c. 5. Bastards also born in any licensed hospital for pregnant women, are settled in the parishes to which the mothers belong. 13 Geo. III. c. 82. When a parish becomes charged with the maintenance of a bastard, then, and not before, the authority of the church-wardens and overseers commences (Say. 95); and they may act without an order from the justices. 3 Term Rep. C. P. 253. It seems, however, that until a bastard attain the age of seven years, it cannot be separated from its mother (Cald. 6.); but may be removed to the place of her settlement, while the age of nurture continues (Carth. 279.); and must under these circumstances be maintained by the parish where it was born. Doug. 7.

The incapacity of a bastard consists principally in this, that he cannot be heir to any one; neither can he have heirs, but of his own body; for being "nullius filius," he is therefore akin to nobody, and has no ancestor from whom any inheritable blood can be derived. As a bastard has no legal ancestors, he can have no collateral kindred; and therefore if a bastard purchases land, and dies seised thereof without issue, and intestate, the land shall escheat to the lord of the fee. Co. Litt. 244. Finch. Law. 117.

By the Roman law, the mother inherited from her bastard child, and vice versa; but there was a great difference between bastards, "nothi," and those they called "spurious." The law did not own the latter, nor allow them sustenance, because they were born in common and uncertain prostitution. "Is non habet patrem, cui pater est populus." The former sort, born in concubinage, which resembles marriage, inherited from their mothers, and had a right to demand sustenance of their natural fathers. They were looked upon as domestic creditors, that ought to be treated the more favourably, for being the innocent product of their parents' crimes. Solon would have it, that the parents should be deprived of their paternal authority over their bastards; because, as they were only parents for pleasure, that ought to be their only reward.

Anciently, in Rome, natural children were quite excluded from inheriting; after their fathers ab intestato: but they might be appointed heirs in general. The emperors Arcadius and Honorius made a restriction; and when there were legitimate children, the bastards should only come in for a sixth, to be shared with their mother. Justinian after-

wards ordered, that they might come in for half; and succeeded ab intestato for a sixth, when there were legitimate.

Bastard might be legitimated by subsequent marriage, or by the emperor's letters. The emperor Anastasius allowed fathers to legitimate their bastards by adoption alone: but this was abolished by Justin and Justinian, lest by this indulgence they should authorize concubinage. The pope has sometimes legitimated bastards. Nay, the holy see has on some occasions dispensed not only with illegitimacy, but with the offspring of adultery, as to spiritual considerations, in allowing of their promotion to episcopacy.

Accordingly the civil law differs from ours in this point, and allows a bastard to succeed to an inheritance, if after its birth the mother was married to the father (Nov. 89, c. 8.); and also, if the father has no lawful wife or child, then, even if the concubine was never married to the father, yet she and her bastard son were admitted each to one twelfth of the inheritance (Ibid. c. 12); and a bastard was likewise capable of succeeding to the whole of the mother's estate, although she was never married; the mother being sufficiently certain, though the father is not. But our law, in favour of marriage, is much less indulgent to bastards.

An attempt was once made to introduce the civil law here in this respect, by declaring children legitimated by a subsequent marriage; but it was rejected: and it was upon this occasion that the barons of England assembled in the parliament of Merton, A. D. 1222, made that famous answer, "Nolumus leges Anglię mutare." 20 Hen. III. c. 9.

But though bastards are not looked upon as children to any civil purposes, yet the ties of nature hold as to maintenance, and many other intentions; as, particularly, that a man shall not marry his bastard sister or daughter. L. Raym. 6^o Comb. 356.

A bastard was, in strictness of law, incapable of holy orders; and though that were dispensed with, yet he was utterly disqualified from holding any dignity in the church. Fortesc. c. 40. 5 Rep. 58. But this doctrine seems now obsolete; and there is a very ancient decision, that a felon should have benefit of clergy, though he were a bastard. Bro. Clergy 20. In all other respects, there is no distinction between a bastard and another man; whereas the civil law, which has been extolled for its equitable decisions, made bastards in some cases incapable even of a gift from their parents. Cod. 6. 57. 5. A bastard may even be made legitimate, and capable of inheriting, by the transcendent power of an act of parliament, and not otherwise (4 Inst. 36.); as was done in the case of John of Gaunt's bastard children, by a statute of Richard II.

Bastardy with regard to the several modes of its trial, is distinguished into general and special bastardy. Till the statute of Merton already recited, the question whether born before or after marriage, was examined before the ecclesiastical judge, and his judgment was certified to the king or his justices, and the king's court either received or rejected it at pleasure. But after the solemn protest of the barons at Merton against the introduction of the civil and canon law in this respect, special bastardy has been always triable at common law; and general bastardy has alone been left to the judgment of the ecclesiastical judge, who in this case agrees with the temporal. (2 Inst. 29. Reeves's Hist. Eng. Law. 85. 201.) General bastardy, tried by the bishop, comprehends two things. 1. It should not be a bastardy made legitimate by a subsequent marriage. 2. That it should be a point collateral to the original cause of action. If the ordinary certify or try bastardy without a writ from the king's temporal courts, it is void; and the certificate must be under the seal of the ordinary. 1 Rol. Abr. 361, 362.

Special bastardy is two-fold: 1st, Where the bastardy is the gift of the action, and the material part of the issue; 2^{dy}, Where

Where those are bastards by the common law that are " muliers " by the spiritual law. (Co. Litt. 134. 1 New Abr. 314. 1 Rol. 357. Hob. 117.) If a man receives any temporal damages by being called a bastard, and brings his action in the temporal courts, and the defendant pleads that the plaintiff is a bastard, this must be tried at common law, and not by writ to the bishop. 1 Brownl. 1. Hob. 179. Godol. 479. Co. Ent. 29.

In an ancient MS. of the time of Edw. III. it is said that he who gets a bastard in the hundred of Middleton in Kent shall forfeit all his goods and chattels to the king. If a bastard be got under the umbrage of a certain oak in Knolwood in Staffordshire, belonging to the manor of Tersey-castle, no punishment can be inflicted; and neither the lord nor the bishop can take cognizance of it. Plott's Stafford. p. 279.

By the stat. 21 Jac. 1. c. 27. a mother of a bastard child, concealing its death, must prove by one witness that the child was born dead; otherwise, such concealment shall be evidence of her having murdered it. But of late years it hath been usual, on trials for these offences, to require some sort of presumptive evidence that the child was born alive, before the other presumption be admitted, that because the death was concealed it was killed by the parent. If a woman be with child, and any one give her a potion to destroy the child, and it kills the woman, this is murder. If a woman great or quick with child takes, or any person gives her, any potion to cause abortion, or if a man strike her so as to kill the child, this is not murder nor manslaughter by the law of England; but the offender may be indicted for a misdemeanour at common law. But if the child be born alive, and afterwards die of the poison or bruises it received in the womb, it is murder on the part of such as administered or gave them. Thus also, if a man procure a woman with child to destroy her infant when born, and the child is born, and the woman in pursuance of that procurement kill the infant, that is murder in the mother, and the procurer is accessory. 1 Hal. P. C. 429, 430, 433. Blackst. Com. vol. i. p. 454, &c. vol. ii. p. 248. vol. iv. p. 65. Burn's Justice, vol. i. p. 217—271.

BASTARD, in respect of *Artillery*, is applied to those pieces which are of an unusual or illegitimate make or proportion. These are of two kinds, long and short, according as the defect is on the redundant or defective side.

The long bastards, again, are either common or uncommon. To the common kind belong the double culverin extraordinary, half culverin extraordinary, quarter culverin extraordinary, falcon extraordinary, &c.

The ordinary bastard culverin carries a ball of eight pounds. See CANNON.

BASTARD, in *Botany*, is applied to several species of plants: as baitard alkanet, for which see LITHOSPERMUM;—balm, see MELITTIS;—cabbage-tree, see GEOFFROYA;—cedar, see THEOBROMA *Guazuma*;—crefs, see THLASPI;—feverfew, see PARTHENIUM;—flower-fence, see ADAMANTINA;—gentian, see SAROTHRA;—hare's ear, see PHYLLIS;—hatchet-vetch, see BISERRULA;—hemp, see DATISCA;—hibiscus, see ACHANIA;—Jesuit's bark-tree, see IVA;—indigo, see AMORPHA;—knot-grass, see CORRIGIOLA;—lupine, see TRIFOLIUM *Lupinaster*;—orpine, see ANDRACHNE;—pimpernel, see CENTUNCULUS;—plantain, see HELICONIA *Bihai*, and CENTUNCULUS;—quince, see MESPILUS *Chamæspilus*;—rocket, see NASADA;—saffron, see CARTHAMUS;—star of Bethlehem, see ALBUCA;—wood-flax, see THESIUM;—vetch, see PHACA.

BASTARD, in *Sea Language*, is used for a large sail of a galley, which will make way with a slack wind.

BASTARD is also used adjectively, or in composition with divers other words, to denote things of inferior or dimi-

utive value. In this sense we meet with bastard coral, bastard alabaster, bastard ananthus, &c.

BASTARD *Scarlet* is a name given to red dyed with hale madder, as coming nearest to the hew-dye, or new scarlet.

BASTARDS are also an appellation given to a kind of faction or troop of banditti, who rose in G. France about the beginning of the fourteenth century, and being with some English parties, ravaged the country, and set fire to the city of Nantes.

Mazery supposes them to have consisted of the natural sons of the nobility of Guienne, who being excluded the right of inheriting from their fathers, put themselves at the head of robbers and plunderers, to maintain themselves.

BASTARDY is a defect of birth objected to one born out of wedlock.

Eustathius maintains, against the course of antiquity, that bastards among the Greeks were in equal favour with legitimate children as low as the Trojan war: others, however, have shown that there never was a time when bastardy was not in disgrace. (See Homer. Il. 6, v. 281. Sophocl. Ajax, v. 1250. Euripid. Ion, v. 529.) In the time of William the conqueror, bastardy seems not to have implied any disgrace; for that monarch does not scruple to assume the appellation of bastard. His epistle to Alan, count of Bretagne, begins, " Ego Willielmus, cognomento bastardus." Du Cange Gloss. Lat. t. i. p. 502.

BASTARDY, *Arms of*, in *Heraldry*, should be crossed with a bar, fillet, or traverse, from the left to the right. Bastards were not formerly allowed to carry the arms of their father, and therefore they invented arms for themselves; and this is still done by the natural sons of a king.

BASTARDY, *Right of*, *Droit de Bastardise*, in the French *Law*, is a right, in virtue of which the effects of bastards dying intestate devolve to the king or the lord.

BASTARDY, *Trial of*. See BASTARD.

BASTARNÆ, in *Ancient Geography*, a people who at first inhabited that part of European Sarmatia that corresponded to a part of Poland and Prussia, towards the Vistula, and who afterwards approached the more southern parts, and established themselves to the left and right of the Tyas or Danaster. The era of their war with the Goths, and of their conquest of these territories, is not precisely ascertained. M. Freret refers it to the interval between the years 282 and 280 B. C. Tacitus says, they had houses; and hence it has been inferred that they were not Sarmatians, because they dwelt in huts. Livy considers them as Gauls, and Strabo presumes that they were a nation of Germans. They seem, however, to have inhabited the region that lay north of the Carpathian mountains, and to have gradually extended themselves towards Poland and the Borysthenes. Many learned persons have represented them as a colony left by the Gauls on the other side of the Carpathian mountains, when they made their progress, under the conduct of Brennus, from the east towards the west. M. de Peyssonel says, that they may be regarded as the founders of the Ruffians and Selavonians.

BASTATAL, in *Geography*, a small island on the eastern coast of the island of Sumatra. S. lat. 1°. E. long. 103° 30'.

BASTAVOE, a bay on the east side of Yell, one of the Shetland islands.

BASTELLICA, a town of the island of Corsica, 5 leagues E.N.E. of Ajaccio.

BASTERIA, in *Botany*. See CALYCANTHUS.

BASTERNA, in *Antiquity*, a kind of vehicle or chariot used by ancient Roman ladies.

Papias thinks, that basterna was first written for *cessera*.
Revised

Rosweild says, it should be *via sterna*, which he concludes from Iudore, who says, *baisterna, via sterna*. But the word seems better derived from the Greek βασιζω, *porto, to carry*.

Salmafius observes, that the baisterna succeeded the *baista*, or litter; from which it differed very little, except that the litter was borne on the shoulders of slaves, and the baisterna borne or drawn by beasts. Casaubon says it was borne by mules. F. Daniel, Mabillon, &c. assert it was drawn by oxen, to go the more gently; and Gregory de Tours gives an instance of its being drawn by wild bulls. The inside they called the *carrea*, or cage: it had soft cushions or beds, besides glasses on each side like our chariots. The mode of baisternas passed from Italy into Gaul, and thence into other countries; and to this we owe our chariots, which, though we call them *currus*, yet have they no conformity to the ancient *currus*, but are in effect baisternas improved. The baisterna appears also to have been used in war, for the carrying of baggage.

BASTI, now BAZA, in *Ancient Geography*, a town of Spain, in Bætica, north-east of Acci, and near the mountains which separate Bætica from Tarragonensis.

BASTIA, in *Geography*, a sea-port town of Albania, in Turkey in Europe, over against the island of Corsica, at the mouth of the river Calamu. N. lat. 39° 40'. E. long. 20° 35'.

BASTIA, a city and sea-port of Corsica, the capital of the island, is situated on its north-east side, and commanded by a lofty mountain, in the centre of which the sea forms a small bay, defended by a mole. It is divided into two parts, called "Terra Nuova" and "Terra Vecchia;" in the former of which is a citadel, surrounded with fortifications. Its harbour, though good, is not large; and affords convenient anchorage for vessels of a small size, but is unfit for the reception of ships of war: and its commerce is inconsiderable. In 1720, Corsica revolted from Genoa; and in 1794, it was attacked by lord Hood, and captured by the British fleet and army. The number of inhabitants is supposed to be about 6000. N. lat. 42° 35'. E. long. 9° 30'.

BASTIA Marina (*Rumphius*), in *Natural History*, a kind of sponge, supposed to be the *Spongia ventilabra* of Gmelin.

BASTIDE, in *Topography*, an appellation given in the southern departments of France, to small country-houses, built by individuals of easy circumstances, in the vicinity of the towns.

BASTIDE de Montfort, *La*, in *Geography*, a town of France, in the department of the Tarn, and chief place of a canton in the district of Gaillac, 5 miles N. E. of Gaillac.

BASTIDE de Seron, *La*, a town of France, in the department of the Arriege, and chief place of a canton in the district of Tarascon; 4½ leagues N. W. of Tarascon.

BASTIDE, *La*, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the district of Castel-Jaloux, 2½ leagues W. S. W. of Tonneins, and ¼ N. of Castel-Jaloux.

BASTIDE de Jourdan, *La*, a town of France, in the department of the mouths of the Rhone, and chief place of a canton in the district of Apt, 4 leagues S. E. of Apt.

BASTIDE d'Armagnac, *La*, a town of France, in the department of the Gers, and chief place of a canton in the district of Nogaro, 4¼ leagues N. N. W. of Nogaro.

BASTIDE de Biarn, a town of France, in the department of the Lower Pyrenées, 4 leagues W. of Orthez.

BASTILE denotes a small antique castle, fortified with turrets. Such was the bastille of Paris, which seems to have been the only castle that retained the name: it was begun to be built in 1369, by order of Charles V. and finished in 1383,

under the reign of his successor. Its chief use was for the custody of state prisoners.

Of the plan and structure of this edifice, which was for several ages appropriated to the clandestine purposes of unfeeling despotism, and which might be justly considered as the abode of human misery, and of the regulations by which it was governed, it is now needless to record any particulars: as it was assaulted and totally destroyed at an early period of the revolution in France, viz. on the 14th of July, in the year 1789. Those who are desirous of acquainting themselves with its history, will find their curiosity gratified in a volume entitled "The History of the Bastille, &c." published in 1793, 8vo. The most satisfactory information relating to the prisoner in the iron mask, who was confined in this wretched dungeon for many years, and concerning whom many conjectures have been made, is communicated to the public in a work entitled "Memoires du Marechal Duc de Richelieu," published at Paris in 1790, in 4 vols. 8vo. The secret is said to have been extorted from the regent by his daughter, who disclosed it to the duke de Richelieu. From the account given in this work it appears, that this unfortunate person was the twin-brother of Louis XIV. born eight hours after this monarch, and who was the unhappy victim of superstition and cruelty. His father, Louis XIII., being weak enough to give credit to a prediction of some impostors, that if the queen should be delivered of twins, the kingdom would be involved in civil war, ordered the birth of this prince to be kept a profound secret; and had him privately educated in the country as the illegitimate son of a nobleman: but on the accession of Louis XIV. the young man gave indications of having discovered his parentage, of which his brother being informed, ordered him to be imprisoned for life, and to wear a mask, in order to prevent his being recognized.

BASTIMENTOS, in *Geography*, small islands near the isthmus of Darien, at the mouth of the bay of Nombre de Dios. They form a good harbour; and one of them has an excellent spring. N. lat. 9° 30'. W. long. 79° 45'.

BASTINADO. See BASTONADO.

BASTION, in the *Modern Fortifications*, a huge mass of earth usually faced with sods, sometimes with brick, rarely with stone, standing out from a rampart, whereof it is a principal part; and answering to what in the ancient fortification was called *propugnaculum*, or a bulwark.

Bastions, some say, were first introduced by Zisca the Bohemian; others attribute the invention of them to Achmet Bashaw, in the year 1480, mentioning the fortification of Otranto as the first instance in which they were used. However, they were well known soon after the year 1500; for Tartalea gives a plan of Turin, which had been completely fortified for some time with four bastions, in his *Questi & Inventioni diverse*, published in 1546. The first bastions, such as those of Turin, and of Antwerp, which was fortified about the year 1540, were small, and removed at a great distance from each other: but they were made much larger, and brought nearer to each other in the citadel of Antwerp, erected under the direction of the duke d'Alva, about the year 1566.

A bastion consists of two faces and two flanks, and an opening towards the centre of the place called the GORGE. —The faces are the lines BC and CS (*Plate I. Fortificat. fig. 1.*) including the angle of the bastion. See FACE. —The flanks are the lines BA, SD. The union of the two faces makes the outmoit or salient angle, called also the angle of the bastion, BCS.

The union of the two faces to the two flanks makes the side-angles called the shoulders, or epaules of the bastion.

And

And the union of the two other ends of the flanks to the two curtains, the angles of the flanks of the bastion.

The foundation of the bastion, i. e. of a work consisting of flanks and faces, is that great rule in fortification, viz. that every part of a work must be seen and defended from some other part: mere angles therefore are not sufficient, but flanks and faces are indispensably requisite.—Thus, if the bastion consists of flanks and faces, as ABCSD, *fig. 1.* all the points may be defended from the flanks; there being none, v. gr. in the face BC, but what may be defended from the opposite flank EL, nor any in the curtain AE, but may be defended from the adjacent flanks BA and EL; nor in any one flank BA, but may be defended from the other EL.

For the proportions of the faces, they are not to be less than 40 toises, nor more than 60; or differing little from 100 yards.

The flanks of bastions are better as they are longer, provided they stand at the same angle under the line of defence; hence the flank must stand at right angles to the line of defence. Indeed, in the ancient fortification, the flank is made perpendicular to the curtain, so as to have the angle out of the enemy's eye; but this is now provided for, by withdrawing the lower part of the flank two or three perches towards the capital line; which part, thus withdrawn, is better, if made concave, than rectilinear; and if double, with a ditch between, than if single.

The business of disposing the flanks of bastions makes the principal part of the art of fortification; it is that on which the defence principally depends, and which has introduced the various forms and modes of fortifying.

If the angle of the bastion be less than sixty degrees, it will be too small to give room for guns; and besides, so acute as to be easily beaten down by the enemies' guns: to which may be added, that it will either render the line of defence too long, or the flanks too short: it must therefore be more than sixty degrees; but whether or not it should be a right angle, some intermediate angle between sixty and ninety, or even whether or not it should exceed a right angle, is still disputed; though those are generally preferred, which are not much less than 90°, and not exceeding 120° or 130°. Hence it follows, that a triangle can never be fortified, because either some or all of the angles will be either sixty degrees, or less than sixty.

Bastions are of divers kinds, *solid, void, flat, cut, &c.*

BASTIONS, *solid*, are those that are filled up entirely, and have the earth equal to the height of the rampart, without any void space towards the centre.

BASTIONS, *void*, or *hollow*, are those surrounded with a rampart and parapet, only ranging round their flanks and faces, so as to leave a void space towards the centre; where the ground is so low, that if the rampart be taken, no retrenchment can be made in the centre, but what will lie under the fire of the besieged.

BASTION, *flat*, is a bastion built on a right line in the middle of the curtain, when it is too long to be defended by the bastion at its extremes.

BASTION, *cut*, is that whose point is cut off, and in lieu thereof has a re-entering angle, or an angle inwards with two points outward: this is sometimes also called *bastion with a tenaille*; and is used either when, without such a contrivance, the angle would be too acute, or when water, or some other impediment, hinders the carrying on of the bastion to its full extent.

BASTION, *compofed*, is when the two sides of the interior polygon are very unequal, which makes the gorges also unequal.

BASTION, *regular*, is that which has its due proportion of faces, flanks, and gorges; the faces being of an equal length, the flanks the same, and the two angles of the shoulder equal.

BASTION, *irregular*, is where this proportion and equality are not observed.

BASTION, *deformed*, is where the irregularity of the lines and angles makes the bastion out of shape: as when it wants one of its demi-gorges; one side of the interior polygon being too short.

BASTION, *demi*, is that which hath but one face, and one flank: called also an *epaulement*.

To fortify the angle of a place that is too acute, they cut off the point, and make two *demi-bastions*, which form a *tenaille*, or a re-entering angle. Their chief use is before a horn-work or crown-work.

BASTION, *double*, is that which, on the plane of the great bastion, has another bastion built higher, somewhat after the manner of a cavalier; leaving twelve or eighteen feet between the parapet of the lower, and the foot of the higher.

BASTION, *Capital of a*. See CAPITAL.

BASTION, *Gorge of a*. See GORGE.

BASTION, *Distance of the*. See DISTANCE.

BASTION *Company in France*. See COMPANY.

BASTITANI, in *Ancient Geography*, a people of Bætica, in Spain. See BÆTICA, and BASTI.

BASTOGNE, in *Geography*, a city of the Netherlands, in the duchy of Luxemburgh, near the forest of Ardennes. It is so populous, so well built, and has so much trade, that it is so untruly called "Paris in Ardennes." N. lat. 50° 6'. E. long. 6° 0'.

BASTON, ROBERT, in *Biography*, a poet of some note in the fourteenth century, and author of several works, was descended of a noble family, and born in Yorkshire, not far from Nottingham. In his youth he became a Carmelite monk, and afterwards prior of that order at Scarborough. He was likewise poet laureat and public orator at Oxford. In 1304, he accompanied king Edward I. in his expedition into Scotland, for the purpose of celebrating the king's victories over the Scots; but being taken prisoner, he was compelled to sing the successes of Robert Bruce, who then claimed the crown of Scotland. He died about the year 1310, and was buried at Nottingham. His poetry, though barbarous, was not contemptible for the age in which he lived. *Biog. Brit. Gen. Dict.*

BASTON, or BATOON, in *Architecture*, denotes a mould in the base of a column; otherwise called a *torc*.

BASTON, or BATOON, in *Heraldry*, a kind of bend which has only one fourth of the usual breadth. The baston does not go from side to side of the escutcheon, as the bend or scarf does, but is broken off short, in form of a truncheon. Its use in English coats of arms is a mark of bastardy: but French heralds introduce it in arms as a difference, a mark of consanguinity.

BASTON also signifies the earl-marshal's staff.

BASTON, French, literally signifying a *staff*, and technically a *verge*, or *mace*, in *Law*, is used for one of the warden's of the Fleet's men, who attends the king's court with a red staff, for taking such to ward as are committed by the court, and likewise attends on such prisoners as are suffered to go at large by licence. *Stats. 1 R. II. c. 12. 5 Eliz. c. 23.* See GIPSTAFF.

BASTONADO, BASTONADE, or BASTINADO, the punishment of beating or drubbing a criminal with a stick.

The word is formed of the French *bâton*, a *stick*, or *staff*.

The bastonade is a punishment used among the ancient Greeks, Romans, and Jews, and still obtains among the Turks.

The Romans called it *sustigatio*, *fustium admonitio*, or *sustibus cedi*, which differed from the *flagellatio*, as the former was done with a stick, the latter with a rod or scourge. The sustigation was a lighter punishment, and inflicted on freemen; the flagellation a severer, and reserved for slaves. It was also called *lympanum*, because the patient here was beat with sticks, like a drum.

The penalty is much in use in the East to this day. The method there practised is thus: the criminal being laid on his belly, his feet are raised, and tied to a stake, held fast by officers for the purpose; in which posture he is beaten by a cudgel on the soles of his feet, back, chin, &c. to the number of one or more hundred blows. *Calmet. Dict. Bib. tom. i. p. 260.*

For the method of inflicting this punishment at Algiers, see ALGIERS. Dr. Shaw (*Trav. p. 253.*) suggests that it was probably in this manner, that St. Paul was "thrice beaten with rods." 2 Cor. xi. 25. The Choufca, whose office it is to inflict this punishment at Algiers, appear to be no other than so many Roman lictors armed with their fasces. The slightest of all the Chinese punishments is the bastinado, which is only used for chastising those who have been guilty of very trivial faults. The criminality of the offender determines the number of blows which he must receive; but the lowest number is twenty. The punishment in this case is considered merely as a simple paternal correction, without any infamy attached to it; and it is ordered by the emperor to be inflicted on his courtiers, who are afterwards received into favour and treated with respect. The baton, or "pan-stee," used for this punishment, is a piece of bamboo, a little flattened, broad at the bottom, and polished at the upper extremity for the convenience of being more easily handled. Every mandarin may use it at pleasure in certain cases, either when any one forgets to salute him, or when he administers public justice. On such occasions he sits gravely behind a table, upon which is placed a bag filled with small sticks, while a number of petty officers stand around him, each furnished with some of these "pan-stees," and waiting only for his signal to make use of them. The mandarin takes from the bag one of the little sticks which it contains, and throws it into the hall of audience. The culprit is then seized, and stretched out with his belly towards the ground; his breeches are pulled down to his heels, and an athletic domestic applies five smart blows of his "pan-stee," another succeeds, and bestows five more, if the mandarin draws another small baton from the bag, and this, by gradation, until the judge is pleased to make no more signals. The criminal, who has undergone this chastisement, must then throw himself upon his knees before the judge, incline his body three times to the earth, and thank him for the cure which he takes of his affliction. *Grolier's China, vol. ii. p. 52, &c.*

BASTONIER, or BASTONIER, in the French *Laws*, an ancient advocate, elected yearly according to seniority, to be the head or master of the community of advocates and attorneys. He is president of the board held for maintenance of the order, and discipline of the *palais*. To him also belongs the commission of the inferior judges, when put under interdict, so long as the interdiction lasts.

BASTONIER is also used for him who keeps the staff of a community, and carries or follows it in processions.

BASTOVA, in *Geography*, a town of European Turkey, in Albania, 18 miles South of Darazzo.

BASTWICK, JOHN, in *Biography*, M. D. born at

Writtle in Essex, in 1593, after passing through the usual school education, was sent to Emanuel college in Cambridge, where, however, he did not continue a sufficient time to take his degree; but with the view of qualifying himself for the practice of physic, he quitted England to visit the principal seminaries on the continent, where, at that time, the different branches of medicine were better taught than in his own country. At Padua he was admitted to the degree of doctor in medicine; but engaging early in theological disputes, and thence exciting the resentment of the clergy, he soon found himself involved in troubles, from which, at a late period, he scarce escaped with his life. In 1624, and before he returned to England, he published at Leyden, "Elenchus Religionis Papijicæ, in quo probatur, neque Apostolicam, neque Catholicam, imo neque Romanam esse," 24to.; and soon after his return, "Flagellum Pontificis et Episcoporum Latianum." Though he declared, in the preface to this work, that nothing in it was intended to affect such bishops as acknowledged their authority from kings and emperors, yet our English prelates, either suspecting that some things in his book were levelled at them, or perhaps not enduring that the conduct of ecclesiastics should be exposed with such freedom by a lay writer, and fearing if he was suffered to go on the same weapon might be turned against them, he was cited by them before the high-commission court, fined 1000*l.* and sentenced to be excommunicated, to be debarred the practice of physic, to have his books burnt, and to remain in prison until he made a recantation. After being confined two years in the Gatehouse, he published "Apologeticus ad Præfules Anglicos;" but that procuring no remission of his sentence, it was soon followed by "The New Litany," in which he taxed the bishops with having an inclination to popery, and exclaimed against the severity and injustice of the high-commission's proceedings against him. For publishing this work, he was sentenced, by the same court, to pay a fine of 5000*l.*, to stand in the pillory in Palace-yard Westminster, and there lose his ears, and to suffer perpetual imprisonment in a remote part of the kingdom. The same sentence was, about the same time, in 1637, passed and executed upon Pryne and Barton. Bastwick was conveyed to Launceston castle in Cornwall, and thence removed to St. Mary's castle in the isle of Scilly, where no one was permitted to visit him. The house of commons, however, in 1640, ordered him, as well as the others, to be brought to London, whither they were attended by vast multitudes of people, with loud acclamations of joy. The proceedings against them were voted illegal, and they were ordered to be remunerated out of the revenue and estates of the archbishop of Canterbury, and the other lords of the commission who had condemned them. Bastwick was alive in 1648. The time of his death is not known. *Gen. Biog. Dict.*

BASVILLE, in *Geography*, a sea-port town in the island of Martinico.

BASZEU, a river of European Turkey, which runs into the Pruth, near St. phanowze, in Moldavia.

BAT, in *Zoology*. See VESPERTILIO.

BAT, *Sea*. See SEA BAT.

BAT, in *Commerce*, a small base silver coin, current in divers parts of Germany and Switzer-land, at different prices.

The bat or stademonse, at Nuremberg, is equal to four croitzers; at Zurich, to $\frac{1}{3}$ of the French crown; at Basil, Schaffhausen, &c. to $\frac{1}{7}$; and at Burn and Feiburg to $\frac{3}{8}$ of the same crown. These last are called short bats.

BATA, in *Botany*. See MUSA.

BATA, in *Geography*. See BATAA.

BATABANO, a town on the south side of the island of Cuba in the West Indies, seated near a large bay, opposite

Pinos inflas, and about 50 miles south-west from the Havannah.

BATABLE LAND. See **BATTABLE.**

BATACALO, or **BATACOLO Bay**, in *Geography*, lies on the east coast of the island of Ceylon, in N. lat. $7^{\circ} 55'$. E. long. $81^{\circ} 3'$. It extends to the south between the main island and a narrow track of land on the east side of it, and is well sheltered from most winds. The Port town, so called, is on the west side of this bay or gulf, 53 leagues N. E. of Columbo. The bay is about 20 leagues to the S. S. E. of Trincomale. Batacolo is a place of comparatively small importance; but the surrounding country, and the bold grotesque rocks which skirt its shores, have deservedly attracted particular attention.

BATACARANG POINT, lies on the east coast of the island of Sumatra.

BATALHA, a monastery in Portuguese Estremadura, about 60 miles to the north of Lisbon, founded by John I. at the close of the fourteenth century, in consequence of the great victory over the king of Castile, and reckoned one of the most noble monuments of what is called the Gothic style of architecture. It has been particularly described by Mr. James Murphy.

BATAN, a town of Asiatic Turkey, in the province of Natolia, 20 miles south of Kutai.

BATARDIERE, a place in a garden, prepared for the planting of fruit-trees, which being transplanted thither from the nursery, are to be placed in espaliers, or elsewhere, to supply the place of dead trees.

BATATAS, in *Botany*. See **CONVOLVULUS.**

BATASAS. See **POTATO.**

BATATAS, in *Entomology*, a species of **ACARUS**, found on the potatoe in Surinam and some other parts of South America. It is rather rough and sanguinous; anterior legs as long as the body. Fabricius.

BATAVI, in *Ancient Geography*, are supposed to have been originally the same people with the Catti or Cattans, who dwelt beyond the Rhine; and being driven from their country by a domestic insurrection, they settled at the extreme borders of Gaul, in an island called "Insula Batavorum," formed by the mouths of the Rhine and the ocean. According to this description, the Batavians possessed South Holland, part of the country of Utrecht, and the island of Betaw in the dukedom of Guelderland. The early history of the Batavi is involved in considerable obscurity. It is certain, however, that about 54 years before the Christian era they were distinguished by their valour, and attracted the attention of Cæsar, who formed an alliance with them. He encouraged them to serve in the Roman armies; and they appear to have fought with him against Pompey at Pharsalia, and to have assisted Augustus in the battle of Actium. They assisted Cæsar in his attacks upon the Gauls, and they every where routed and dispersed that ferocious and warlike people. The Batavian cavalry bore the highest reputation, and the infantry fought with the same order, discipline, and intrepidity in the marshes and waters as upon the firm land; and even the Romans dreaded their resentment. They became the body-guard of the emperors, who reposed equal confidence in their fidelity and courage; and they retained this honourable trust till they were dismissed by Galba, though with tokens of favour and esteem. In all important expeditions, in every dangerous enterprise, and where obdurate boldness was required, the Batavians were selected. They generally composed the foremost hope of the Roman army, sustained the first shock of the enemy, and made the first attack with an impetuosity peculiar to themselves. They were not only honoured by the title of allies

to the empire, but distinguished by the appellation of the friends and brethren of the Romans; which denomination was particularly applicable to the inhabitants of Betaw, an island formed by the Rhine and Vahal or Waal. Their government seems to have been monarchical, and it is conjectured that Claudius Civilis was descended from their kings. But though the Romans indulged them in an exemption from tributes and taxes, it was not consistent with the views they had adopted of universal dominion to allow them the enjoyment of their liberty. They built towns, and made establishments in their territories; and this rude people, flattered by the luxury and the amusements which they introduced among them, did not immediately perceive the dangerous policy which directed them. They were soon, however, informed of the treachery of their allies, by the oppression and injustice which they began to exercise. When Vitellius and Otho disputed the empire, and the German nations attempted to recover their liberty, the Batavians followed their example. Alarmed for the interest and the rights of their nation, Julius Paulus and Claudius Civilis set themselves to oppose the practices of the Romans, and to emancipate themselves from their dominion. But Fonteius Capito, the Roman commander, considering them as rebels, made himself master of their persons; and having beheaded the former, he loaded the latter with chains, and sent him to Rome. The death of Nero, however, which happened about this time, delivered Civilis from the danger which threatened him; and the weak and impolitic Galba suffered him to return to his country, without inquiring into his crime, or into his merit. This illustrious chief then prepared to gratify his resentment, and to recover and vindicate the liberty and honour of his nation. He called an assembly of his community, and representing the evils of tyranny, inculcated a disdain of submission and servitude. His countrymen submitted themselves without reserve to his conduct; and uniting with the Frisii and the Cominesates, he declared war against the Romans. Gaining an accession of strength from the Tungrians, who deserted the Romans, and from some natives of Batavia, who served as rowers in the Roman fleet, he was enabled to defeat the Romans and put them to flight. He was afterwards joined by eight Batavian cohorts, who abandoned Vitellius, by whose orders they were marching to Rome, and also by some other German tribes; and thus aided and encouraged, he obtained some further success. But upon the arrival of Cerealis, the Roman general, he received a total overthrow, and was at length obliged to abandon his own island, whither he had retreated, to retire beyond the Rhine, and to submit to the Romans. A conference taking place between Cerealis and Civilis, the issue of it was an entire submission on one side, and an unreserved pardon on the other. The Batavians remained in the same condition in which they were before the war broke out; that is, exempt from all tributes, and only obliged to supply the Romans with troops when required. We know little more of the ancient history of the Batavians than that the fierce and warlike spirit of the people obliged the Romans to maintain strong garrisons on the banks of the Rhine; that they revolted against Constantine; that they performed signal services to Theodosius in Britain; and that, with the rest of the empire, they fell under the power of the Franks; and were governed by Charlemagne, and his descendants, until, upon the decline of that house, the great lords and officers of the crown, taking advantage of the weakness of the reigning princes, rendered their governments hereditary in their families. From the Batavi, the seven united provinces derived the name of Batavia, which since the French revolution has been recognized in the appellation of the

Batavian republic. Cæf. Com. l. vii. Tacit. Hift. l. v. l. vii. Sueton. in Galb.

BATAVIA CASTRA, a citadel of Vindelicia, fo called from the cohorts Batavia, in garrifon under the commander in Rhaetia; now **PASSAU**, fituated in Bavaria, at the confluence of the Danube, Inn, and Ilb.

BATAVIA, in *Geography*, the celebrated capital of the Dutch poffeffions in the East Indies, and denominated the "Queen of the East," on account of the beauty of its building, and its immense trade. It is a fea-port town on the north coaft of the ifland of Java, fituated very near the fea, on a fertile plain, bearing evident marks of having been left or thrown up by the fea, in the kingdom of Jacatra, upon the river of that name, which, running through the middle of the town, divides it into two parts. To the north of the city is the fea-shore; behind it to the fouth, the land rifes with a gentle, and fcarcely perceptible, acclivity towards the mountains, which lie 15 or 16 Dutch miles, or leagues, inland; one of which, as being very high, bears the name of the Blue mountain. This city was founded in 1619 by the governor-general, John Peterfon Koen, who captured and destroyed the town of Jacatra, near the fpot where the former town was fituated; and he gave it the name of Batavia, though it is faid he much wifhed to have called it "New Horn," from the place of his nativity, "Horn" in North Holland. Although it was then an inconfiderable place, with regard both to ftrength and beauty, he declared it the capital of the Dutch fettlements in India; and his choice of the fituation was fo juft, and his plan fo well contrived, that it rofe with unparalleled rapidity to that degree of magnificence and importance which has rendered it both the admiration and terror of all the more eaftern nations of India. It ftill retains a very confiderable rank and influence; although, for the laft 50 years, it has much declined both as to opulence and population. The form of the city is an oblong fquare, $\frac{1}{2}$ of a mile long, and $\frac{1}{4}$ a mile broad, interfefted by the river already mentioned, which runs from north to fouth, and is croffed by three bridges. The breadth of the river, within the city, is about 160 or 180 feet; and paffing the caftle and admiralty wharf, it difcharges itfelf into the fea. On both fides of its mouth are long piers of wood and brick-work, about 3,800 feet long, taken from the moat of the city: between which, on the weft fide, the veffels belonging to the free merchants are laid up and repaired; but along the eaft fide, the paffage lies open for the lighters, which go into and out of the city with the cargoes of the fhips. Oppofite to the outward point of the eaftern pier is a horn-work, commonly called the "Water-fort," conftructed of a kind of coral rock, and having, mounted or difmounted, fourteen guns, and two howitzers. It confifts of a parapet, retained by a wall; but the parapet has been much neglected, and the wall is nearly destroyed by the conftant working of the fea. This fort is protected on the land fide by a noxious fwamp, and towards the fea, on the north-weft, by extenfive flats, over which even boats cannot pafs. The only good approach is that by the channel, which it fees and defends. On the weft fide, about a quarter of a mile from the water-fort, is a battery, mounting feven guns, bearing down the river; and oppofite to this is a battery of fix guns, facing the river, and two to the eaftward. Each divifion of the city on either fide of the river has two canals, running parallel with the longeft fides, and interfefted at right angles by crofs-canals. Thefe canals join the great canal, or river, at the diftance of half a mile from the entrance; and below their junction is laid a boom of wood, armed with iron fpiques. The city is encompassed by a wall of coral rock, ferving as a facing to the rampart behind

it; and alfo by a moat, having feveral fluices, into which water is conveyed from the river. Sir George Staunton fays, that a part of the town-wall is built of lava, which is of a dark blue colour, and of a very hard denfe texture, emitting a metallic found, and very much refembling fome of the lava of Vefuvius. It is brought from the mountains in the centre of Java, where a crater is ftill fmoking. The rampart is defended by twenty or twenty-one ballions, which, as well as the wall, are in a ruinous ftate. Small projeftions, of various forms, are conftructed at intervals of about 350 feet, each of which generally mounted three guns. At fhort diftances from the town, three or four fmall ftar-forts of earth are erected in particular paffes, probably for defence againft the inhabitants of the ifland. The caftle or citadel of Batavia, which was formerly on the fea-fide, is now, by the continual increafe of the mud-banks before it, diftant from the fea more than 100 roods, and is feated on the eaft bank of the river. It covers about 200 roods of ground, and is a regular fquare fortrefs, built of coral-rock brought from fome of the adjacent iflands, compofed of that material. It has neither ravelins nor outworks. Two guns are mounted on each flank, and two, or fometimes three, on each face: neither "en barbette" nor "en embrafure;" but in a fituation between both, having the difadvantages of both without the advantages of either. The wall is of mafonry, about 24 feet high. It has no ditch, but a canal encompasses it at fome diftance. It has no cordon; and the length of the exterior fide of the work is about 700 feet. Between the moat and the buildings within the fort, on the fouth fide, is a large area or efpalanade. In the centre of the buildings that look towards the city, is a great gate, and then a broad paffage, with warehoufes on each fide, leading to another efpalanade, on the north fide, enclosed between the ramparts and the buildings, which are appropriated to the ufe of the company. The government-houfe, which forms the left wing of the buildings looking to the fouth, is provided with numerous and convenient apartments, but uninhabited. In it is a large hall, in which the council of India generally affemble twice a week. Near this is a little church or chapel, called the caftle church; and at a fmall diftance is a corps-de-garde, where a party of dragoons always mount guard. Over the caftle-bridge is a fpacious plain or fquare, planted with tamarind trees, which afford an agreeable fhade; and the entrance into it from the city is over a bridge and through a large ftately gate, mounted with a lofty cupola, from which arifes an octagon turret with a large clock, the only public one at Batavia. On the left fide of the gate is a large building, ferving as a corps-de-garde, having in front a long gallery, refting upon a row of pillars; where is ufually pofted a captain's guard of grenadiers. On the weft fide of the fquare ftand the company's artillery-houfe, and the difpenfary or promotion-magazine, both of which extend to the fide of the river, fo that the goods are taken in and out of the lighters with the greateft eafe. On the oppofite fide is the non-magazine, and the grafs-plot or place of execution, which is an artificial fquare entrance, upon which are a gallows and fome pofts; and behind it is a fmall building, with windows, opening towards the place of execution, where the counfellors of juftice may behold the completion of their fentences. Upon the plain are arranged pieces of iron and brafs artillery, and other warlike implements.

Batavia has five gates; and near to that on the north fide, to the weft of the river, is the admiralty wharf; and near this, the warehoufes for naval ftores, and the workfhop of the carpenters, coopers, fail-maker, and fmiths, with other offices and houfes that relate to the fhipping. In the fouth-eaft corner of the city, clofe to the ramparts, lies the workmen's

quarter, called "Ambagtsfc wartier," in which all the workmen and labourers employed by the company reside. Besides a great number of Europeans, there are more than a thousand slaves who belong to this quarter.

Besides the public buildings already mentioned, Batavia has a town-hall, which is well situated; two large and convenient hospitals, and several churches; three of which, within the city, are appropriated to the reformed religion, in which service is performed in the Dutch, Portuguese, and Malay languages; and one without the gates, called the outer Portuguese church. There is also a Lutheran church not far from the castle, provided with a fine organ and a very handsome pulpit. These churches are supplied every Sunday by twelve clergymen of the reformed religion, and three Lutheran ministers. One of these clergymen is deputed, once every year, or sometimes only once in two years, upon a visitation to the company's possessions on the west coast of Sumatra; and to the individuals thus employed, the visitation is rendered lucrative by the merchandize which they take with them for sale. The Chinese have also several temples, which are tolerated by government; but the exercise of the Roman Catholic religion is obstinately prohibited.

In the districts round Batavia, immediately subject to the Dutch, it is calculated, says Sir George Staunton, that near 50,000 Javanese families are settled, containing upon an average six persons to a family, or 300,000 persons in the whole. The city of Batavia, including the suburbs, contains near 8000 houses. Valentyn (cited in the *Mod. Un. Hist.*) states the number of houses in the city and suburbs at 4,770. Huysers, a more recent Dutch writer, who was long resident at Batavia, and who published his account in 1778, estimates the number of houses in Batavia at 3,500; but he does not say whether he included the suburbs. The number and description of inhabitants in 1778, according to this writer, were as follow: viz. 468 European burghers, 5,582 native Christians, 4,873 Mardykens or manumitted slaves of all nations, 23,309 Chinese, 289 Amboynese, 278 Bandamese, 966 Moors, 254 Gentoos, 1,852 Malays, 324 Buntanners, 1,983 Macassers, 3,707 Bougainese, 104 Timorese, 189 Mandharise, 85 Sumbawers, 13,073 Baliens, 33,408 Javans, and 20,072 slaves; making in all 110,816, exclusively of women and children, and of the company's servants. The company's establishment consisted, in 1776—1777, of 613 persons in civil, and 35 in ecclesiastical employments, 99 surgeons and assistants, 125 belonging to the artillery, 875 seamen and marines, 1,571 soldiers, and 903 mechanics; in all, 4,221 Europeans, besides 703 natives in their service.

The houses at Batavia, belonging to the Dutch, are well built, chiefly of brick, clean and spacious, and their construction is, for the most part, well adapted to the climate. The doors and windows are wide and lofty; the ground-floors are covered with flags of marble, which being sprinkled frequently with water, give a pleasant coolness to the apartment; but when Sir George Staunton visited the place, a considerable proportion of the houses was untenanted; a circumstance which indicated a declining settlement. The houses of the Chinese are low, and crammed with people. Most of them dwell in the southern and western suburbs, which are called the Chinese "Campon." Before the revolt of the year 1740, they had the best quarter of the city allotted them, to the west of the great river; but when in that commotion all their houses were burnt to the ground, the whole quarter was converted into a "passar," or market, where at present all kinds of provisions are daily exposed to sale. Before the perpetration of this massacre, several thou-

sand Chinese adventurers resorted to Batavia, allured by the prosperity of their countrymen already settled there. The number of these colonists, together with the robberies and murders committed by them, excited a considerable degree of apprehension; which induced Van Imhof, who was at that time a member of the council, to propose, that those who could not prove that they were gaining an honest livelihood, should be seized and transported to Ceylon, and there employed in mining and other labour for the service of the company. The execution of this order produced a tumult and an insurrection; and thousands of the Chinese retired from the city, and collecting a strong force, ravaged the country and assaulted the capital. The civil and military inhabitants united in repelling them. But a fire taking place soon after among the Chinese buildings in the city, several of the owners were accused of opposing with arms the extinguishment of it, with a view, as it was said, of allowing the conflagration to spread through the whole town, that in the moment of confusion they might assassinate the Europeans, and become masters of the place. The alarm was such, that the Dutch government gave instant orders to put all the Chinese heads of families to death; and the sailors from the vessels in the road were brought ashore, and induced, for the sake of plunder, to share in executing the bloody edict. All the Chinese, without distinction, men, women, and children, were put to the sword; and the innocent and guilty were indiscriminately exterminated. Whence this barbarous order issued has been a subject of unsatisfactory investigation. The governor-general Valkenier, and his brother-in-law Helvetius, were accused by the public voice of directing the massacre; but their guilt was never proved. The deed itself was condemned by the directors of the company in Holland; and much apprehension being entertained that the fact would excite the indignation of the emperor of China, deputies were sent to him in the following year, to apologise for the measure on account of the necessity of the case. These deputies were agreeably surpris'd to find that the emperor calmly answered, that "he was little sollicitous for the fate of unworthy subjects, who, in the pursuit of lucre, had quitted the country, and abandoned the tombs of their ancestors." The Chinese, however, are said to be now as numerous as ever in and about Batavia; and it is acknowledged by the Dutch, that the settlement could scarcely subsist without their industry and ingenuity. The quarter of the suburbs which they occupy is crowded with shops containing all kinds of goods; those of their own manufacture, and such as they receive annually from China, or purchase from the European importations. The number of Chinese, who live both within and without the walls of the city, cannot be precisely determined; but it must be very considerable, as the company receives a poll-tax from them of more than 40,000 six-dollars. Every Chinese who has a profession is obliged to pay a monthly poll-tax of half a ducatoon, or 3s. sterling; but women, children, and those who have no trade, are exempted from this tax. They are under a chief of their own nation, called the Chinese captain, who lives within the walls, and has under him six lieutenants in different districts. A flag is hoisted at his door on the first or second day in every month, and the Chinese that are liable to the tax are then obliged to repair to him for the payment of it. Each house in Batavia pays annually an assessment of half a month's rent, which is expended in dragging and cleansing the canals, and in repairing the town-hall and other buildings belonging to the city. The churches are repaired out of the duties levied upon funerals. At Batavia a bank of circulation has been established for

some years, which bank is united with the Lombard or bank for lending money on pledges. This bank is under the administration of a director (who is generally a counsellor of India), two commissaries, a cashier, and a book-keeper. Its capital is computed to amount to between two and three millions of rix-dollars, or between 435,000*l.* and 650,000*l.* sterling.

The suburbs of Batavia are remarkable on account of their considerable extent, uncommon pleasantries, and great population. They are inhabited by Indians of various nations, and by some Europeans; but the quarter of the Chinese is the most populous, and forms of itself a city. None of the streets of Batavia are paved; but along the sides of them near the houses are stone foot-paths, about three or four feet broad. The streets and canals are planted on each side with large trees, generally the "onophyllum catophyllum," and "calaba," the "canarium commune" and others of a fearful sort. The Dutch, who are so fond of gardens in Holland, have indulged that taste to a great extent at their houses in the environs of Batavia, which are every where interspersed with rivulets, by which the circumjacent rice plantations are inundated, and fertilized in the proper season. The country, though it be a fenny district, of which a gentleman upon the spot used the strong expression, "that the air was pestilential, and the water poisonous," is nevertheless every where so verdant, gay, and fertile, interspersed with such magnificent houses, gardens, avenues, canals, and draw-bridges, and so formed in every respect to please, if health could be preserved in it, that a youth just coming from sea, and enraptured with the beauty of every object he saw around him, but mindful of the danger to which life was exposed, could not help exclaiming, "What an excellent habitation would it be for immortals!" There are five principal roads which lead from the city towards the country, and they are all planted with high and sturdy trees, and adorned with handsome houses and pleasant gardens.

As to the habits and mode of living of the inhabitants of Batavia, they very much depend on the views and dispositions with which they resort thither, on the situation which they occupy, and on the qualities of the climate. The native Javanese are in general too remote from civilization to have any wants that are not easily satisfied, in a warm and fertile climate. No attempt is made to enslave their passions; and they find the government of the Dutch less vexatious than that of others who divide some share of the sovereignty of the island with them. As for the Chinese, who are constantly resorting thither from China in the vessels called "junks," their views are similar to those which influence the natives of Holland, and they are alike actuated by the desire of accumulating wealth in a foreign land; both the one and the other were trained in their own country to habits of idleness; but upon their arrival in Batavia, they are placed in different circumstances, and acquire different manners. The Chinese, having no prospect of advancement by favour and interest, apply with diligence to the occupation that is assigned them, and by exertion and economy meliorate their condition, without being able to gratify their ambition by the attainment of any public offices. In the city, they become retailers, clerks, and agents; and in the country, they are farmers, and the principal cultivators of the sugar-cane. Thus they at length acquire fortunes, which they value by the time and labour required to earn them; and this gradual acquisition makes no change in their disposition or mode of life; their industry is not diminished, nor is their health impaired. The Dutch, on the contrary, who are sent out by the company to administer their affairs in Asia,

become soon sensible that they have the power, wealth, and possessions of the country at their disposal. Those who survive the depredations of the climate, mount by a quick gradation to offices, lucrative but not laborious. Their influence likewise enables them to speculate in trade with great advantage. The drudgery of business is readily undertaken by the Chinese, who, like the native Bamias and Debasies in Calcutta and Madras, are employed as subordinate instruments; while their principals find it difficult, under such new circumstances, to retain their former habits, or to resist a propensity to indolence and voluptuousness, though often attended with the sacrifice of health, if not of life. Convivial pleasures, among others, are frequently pursued to excess. "The Chinese," says Stavorus, "are like the Jews in Europe, very cunning in trade, both in the largest dealings, and in the most trifling pedlary. They are so desirous of money, that a Chinese will run three times from one end of the city to the other, if he has the prospect of gaining a single penny." He adds; "in doing business with them, the greatest care must be taken to avoid being cheated." In stature they are rather short than tall, and in colour not so brown as the Javanese. Their heads are shaved all round, except a bunch of hair on the middle of the crown, which is twined with a ribbon that hangs down the back. Their dress consists of a long robe of nankeen or thin silk, with wide sleeves, and under it they wear drawers of the same, which cover the legs. In their houses they hang up in certain niches, images of their "joo'tjes" or idols, painted on Chinese paper, before which they burn lamps and incense. This joo'tje they consider as an evil spirit, and therefore they continually supplicate him not to do them any harm. In their adorations, they prostrate themselves before him, and express their reverence by striking their heads continually against the ground. They likewise consult their idol by a peculiar mode of divination, when they engage in any important undertaking. Notwithstanding this superstition, the Chinese are accused of gratifying their lusts by the most detestable violations of the law of nature. Their tombs are magnificent and costly; and great numbers of them are to be seen about half an hour's walk from Batavia, on the road to Jaccatra. When a Chinese of any note dies, his death is formally announced to all the branches of the family. The body is washed, perfumed, and dressed in the best apparel of the deceased. The corpse is then seated in a chair; and his wives, children, and relations, fall down before it and weep. On the third day it is put into a coffin, and placed in one of the best apartments, hung with white linen, the colour appropriated by them to mourning. In the middle of the apartment is erected an altar, on which is placed the portrait of the deceased, with incense burning near it. On one side of the coffin stand the sons, dressed in white coarse linen, exhibiting every sign of sorrow; while the mother and female relations are heard lamenting behind a curtain. On the day of burial, the whole family assembles, and the corpse is carried to the grave with much solemn pomp. Images of men and women, relations of the family (in the manner of the ancient Romans), and even of animals, together with wax tapers and incense-burners, are carried first in the procession. Then follow the priests with musical instruments; and after them the corpse upon a bier, attended by the sons of the deceased, clothed in white, and leaning upon crutches, as if disabled by grief from supporting themselves. The female relations are carried in chairs, hung with curtains of white silk, that conceal them from view; but their lamentations are distinctly heard; and other women are hired, who are trained to utter shrieks still louder and more piercing. Previously to the funeral, a table with fruits and other eatables

is laid before the corpse, and wax figures of servants placed on each side as attendants upon it. The Chinese visit the graves of their ancestors from time to time, strewing them with odoriferous flowers; and when they depart, they leave a few small pieces of silk or linen before the entrance, and sometimes boiled rice or other victuals, which are speedily made away with at night.

The mode of living practised by the Europeans, either from Holland or any other nation, that reside at Batavia, is very nearly the same. In the morning at five o'clock, or when the day breaks, they rise; and the table is spread at an early hour. Besides tea, coffee, and chocolate, fish and flesh are served for breakfast; and when this is finished, Madeira, claret, gin, Dutch small-beer, and English porter, are laid out in the portico before the door of the great hall, and pipes and tobacco are presented to every guest, with a bright brass jar for a sitting-dish. Those who have business appear at their proper stations at eight o'clock, and remain employed till between the hours of eleven and twelve. Their dinner hour is one o'clock; but immediately before dinner, two men slaves go round with Madeira wine, of which each takes a large glass. Then follow three female slaves, one with a silver jar, containing plain or rose water for washing; a second with a silver basin and low cover of the same metal, pierced with holes, to receive the water after it has been used; and the third with towels for wiping the hands. During dinner, a band of music plays at a little distance. The musicians are all slaves who have been instructed for this purpose. A considerable number of female slaves attend at table, which is covered with many dishes. Dinner is immediately followed by coffee. After drinking coffee, each person retires to a bed, consisting of a mattress, bolster, pillows, and chintz counterpane, but no sheets; and puts on his night-dress, a muslin cap, and loose long cotton gown. A bachelor is attended by a female slave, who fans him while he sleeps. About six they rise, dress, drink tea, take an airing in their carriages, and form parties for the evening. The morning meetings are composed generally of men, as the ladies seldom choose to appear till evening. "Married men," says Stavonius, "seldom give themselves much concern about their wives, nor shew them much regard. They seldom converse with them, at least on useful subjects, and such as concern society, with which of course they are little acquainted. Few of these ladies are natives of Europe, but many are descended from Dutch settlers here; and they are educated with some care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to those of the native inhabitants of Java. A pale languor overspreads the countenance. In their own houses, they dress like their slaves, with a long red chequered cotton gown descending to the ankles, with large wide sleeves. They wear no head-dress, but plait their hair, and fasten it with a silver bodkin on the top of the head. The colour of their hair is almost universally black; they anoint it with the oil of the cocconut, and adorn it with chaplets of flowers. When they go abroad, and particularly to their evening parties, they dress magnificently in gold and silver spangled muslin robes, with a profusion of jewels in their hair, which is worn without powder. They never attempt to mould or regulate their shape by any foreign idea of elegance, or any standard of fashion; and, therefore, exhibit a striking contrast to the Dutch ladies. Every native lady is constantly attended by a female slave, who sits at the feet of her mistress on the floor, holding her gold or silver box, the compartments of which contain arca-nut, cardamom seeds, pepper, tobacco, and slaked lime; all which, mixed together in due proportions,

and rolled within a leaf of betel, constitute a masticatory of a pungent taste, that is in general use. In public assemblies, when the ladies are incommoded with heat, they retire to change their dress, and return, without ceremony, in a more light and loose attire. Their example is followed by the gentlemen, who appear in white jackets, sometimes adorned with diamond buttons. The elderly gentlemen lay aside their wigs, and put on night-caps. The members of the government, except on these occasions, appear abroad in crimson velvet; their carriages are distinguished by peculiar ornaments; and they receive homage from others not of their rank. One of the gates of the city is opened only to let them pass. The Indian women marry young, generally at twelve or thirteen years of age; they have seldom many children, and they are old women at thirty. They are remarkably fond of bathing and ablutions; and use for this purpose a large tub containing three hogheads of water, in which they immerse the whole body at least twice a week; and some do this in the morning, in some of the running streams out of the city. They manifest a most excessive jealousy both of their husbands and of their female slaves; and when they discover the slightest familiarity, punish the latter with a variety of tortures; and of the former they avenge themselves in kind. The coaches used at Batavia are small and light, and for keeping these a yearly tax is paid to the company. Services of a domestic or menial kind are chiefly performed at Batavia by slaves. Three thousand of both sexes are annually brought hither from the coast of Malabar, Bengal, Sumatra, and other parts; but in the greatest number from Celebes. Their treatment is in general mild and gentle, though some instances of barbarity and inhumanity occur. They are not forced to excessive labour, and they are allowed sufficient sustenance. However, many of the males, who had formerly, perhaps, led an independent life before they were made captives in war, have taken offence against their masters upon slight occasions, and wreaked their vengeance by assassination. To the apprehension of such an event is ascribed the preference given at Batavia to female slaves, for every use to which they can be applied; and therefore the number of those that is purchased far exceeds that of the other sex. The slaves that are determined on revenge, often swallow, for the purpose of acquiring artificial courage, an extraordinary dose of opium, and soon becoming frantic as well as desperate, they not only stab the objects of their hatred, but fall forth to attack in like manner every person they meet, till self-preservation renders it necessary to destroy them. They are said in that state to be "running a muck;" so called because, during their frenzy, they continually cry out, "amok! amok!" which signifies "kill! kill!" and their fury has been erroneously ascribed to opium, whereas in reality it is the effect of unruly passion. Instances of it are not more common among slaves than among free natives of the country, who in the anguish for losing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the urgency of some other passion or misfortune, have recourse to the same remedy, with the same fatal effects. A fondness for play, and also for opium, is not uncommon among the Chinese also at Batavia; but by habits of restraint and moderation, they are prevented from falling into the same frantic excesses. The Chinese at Batavia are accustomed to keep gaming-houses, which are the means of seduction and ruin to the greatest part of the slaves in the city; and these pests of society are under the protection of the municipal government, the officers of which pay to the company, as a consideration for the profits accruing from them, a monthly contribution

contribution of 3,100 six-dollars, or upwards of 8,000*l.* sterling per annum.

The chief government of Batavia, and of all the possessions of the Dutch East India company in Asia, is vested in the council of India, at the head of which is the governor-general, who resides at a superb mansion near Batavia, possessing unbounded power, assuming a state, and exacting tokens of respect, much greater than any European monarch claims. The next in rank is the director-general, who is the old councilor of India; and to him are entrusted the direction and controul of the trade of the company throughout all India, and to Europe. Next in order follow the five ordinary and five extraordinary councilors of India. To the servants of the company justice is administered by an assembly called the council of justice, independent of the council of India, and consisting of a president, eight ordinary members, and two adjutors, taken from the company's servants. The citizens and free merchants of India, who are not in the company's service, are amenable to a separate municipal court of justice, called the board of schepens or aldermen, eight in number, with a president who is a member of the council of India. The punishments inflicted at Batavia are exceedingly severe, especially such as are inflicted upon the Indians; of these the chief, and the most terrible, is *IMPALMENT*. For taking alive those slaves who are guilty of the acts of murder called "mucks," the officers of justice are provided with a pole ten or twelve feet in length, at the end of which is a kind of fork, made of two pieces of wood three feet long, which are furnished within with sharp iron spikes: this is held before the object whom they wish to apprehend, and in his frenzy he runs into it, and is thus taken. If he happen to be mortally wounded, he is immediately broken alive up on the wheel, without any form of trial, in the presence of two or three of the councilors of justice.

The orphan-chamber at Batavia serves for the whole of the Dutch possessions in India; and the board consists of a president, who is a councilor of India, and six regents, who are appointed by the council of India, with subordinate clerks. There are several other courts or boards; as the commissioners of dykes and sluices, those of bankruptcies, a court of common pleas, a board of controul over marriages, and several others.

The establishment of regular troops at Batavia, according to the report of captain Parish, cited by Sir George Staunton, consists of 1,200 Europeans, of whom 300 are artillery, and the rest infantry. But as this number cannot be maintained complete in this unhealthy climate, 500 natives were employed, and thus the establishment of European regulars was reduced to 700. Three hundred volunteers of the town are also formed into two companies, but not disciplined. The irregulars are very numerous, consisting of enrolled natives of Java, who have never been embodied, and of Chinese, whom the jealousy of the Dutch allows to be armed only with lances. This establishment appears to find for any effectual resistance. Although every man who settles at Batavia must take up arms in its defence, it is acknowledged by one of the councilors of the Indies, that their chief dependence was on the havoc which the climate was likely to make amongst the enemy's forces. The chief protection to their ill-manned vessel lying in this port, is afforded by the fortified island of *OSRUSI*, which is well situated to command the channel that forms the principal passage into the road.

The climate of Batavia is singularly unhealthy, and has proved the occasion of disease and of death to many of the Dutch settlers, and other Europeans who have transiently

visited this place. The city is situated in the midst of swamps and stagnant pools, whence proceeds every morning a collection of pestilential vapours, whenever the sea-breeze sets in and blows over this morass. The meridian sun raises from the shallow and muddy canals which intersect the town, deleterious miasmata into the air; and the trees, with which the quays and streets are crowded, impede the course of the air, by which the putrid effluvia would in some degree be dissipated. Besides the noxious circumstances of a local kind peculiar to this place, the sudden transition from a cold northern region to the middle of the torrid zone, without the adoption of those habits that are requisite in the latter, must render the human frame more liable to be affected by any causes of disease. Hence it happens that preventive medicines are taken almost as regularly as food, and everybody expects the returns of febriles, as we do the seasons of the year. There are few examples of strangers who remain long in Batavia without being attacked by fever, which is the general denomination in that place for every kind of illness. The disorder at first is commonly a tertian ague, which after two or three paroxysms becomes a double tertian, and then a continued remittent that frequently carries off the patient in a short time. The Peruvian bark is seldom prescribed in any stage of the disease, or it is given in such small quantities as to be productive of little benefit. The chief, or rather the sole medicine administered, is a solution of camphor in spirit of wine. It is supposed, that of the Europeans of all classes who come to settle in Batavia, not always half the number survive the year. The place resembles in that respect a field of battle, or a town besieged. The frequency of deaths render familiar the mention of them; and little signs of emotion or surprise are manifested, on hearing that the companion of yesterday is to-day no more. When an acquaintance is said to be dead, the common reflection is, "Well, he owed me nothing;" or, "I must get my money of his executors." It appears by a calculation, that the company lose, in general, every year, full one-fifth of their servants. It is observed, however, that this climate is not so fatal to the female Europeans as to the other sex. They seldom expose themselves to the heat of the sun, make frequent use of the cold bath, and live more temperately than the men; and, for these reasons, they may suffer less from the insalubrity of the climate. In the lower town, on the north side, the mortality is greater, where uninhabited houses contract a foul and infectious air, than in the other parts of the city that are more fully inhabited. On this account, people not only leave the lower town, but abandon the city altogether, and reside in gardens without the walls, and at as reinote a distance as their employments will allow. This kind of migration increases from year to year, and will probably, in the lapse of time, produce the total abandonment and ruin of Batavia. The most tolerable season here is from March or April to November, when the rains begin, which last the rest of the year. The sea-breeze sets in about ten o'clock in the morning, and continues till four or five in the afternoon; it becomes then calm till seven or eight, when the land-breeze commences, and continues at intervals till day-break, followed by a calm for the remaining hours of the twenty-four. The heat of the weather at Batavia is not so excessive as in some other parts of the east. From July to November, Stavorinus observed, that his thermometer, which hung in the shade in the open air, stood generally between 84 and 90 degrees of Fahrenheit's scale, in the hottest part of the day; once indeed the mercury rose to 92°: in the morning, it seldom fell lower than 76°. The barometer scarcely ever varies from the mean height. Sir George Staunton,

who arrived at Batavia in March, informs us, that in the road, Fahrenheit's thermometer, during his continuance, was from 86 to 88 degrees; and in the town, from 88 to 92 degrees: but that its variations by no means corresponded to the sensations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumstance has little effect upon the thermometer. In the night, the thermometer, instead of sinking as it does in colder countries, sometimes 20°, keeps generally here within 4 or 5 of what it attains in the shade when the sun is at its highest elevation. The unhealthiness of the place, as Stavorinus justly observes, is owing not so much to the heat, as to the morasses by which the city is surrounded, and particularly to the mud which the sea throws up, and which it leaves, at low water, exposed to the sun. With care and attention on the part of the government, it is reasonable to imagine, that this evil might be greatly diminished, if not wholly removed. The general apprehension of the unhealthiness of Batavia for Europeans, deters most of those who can reside at home with any comfort, from seeking a settlement there, notwithstanding the temptation of fortunes to be quickly amassed in this place. From this circumstance it happens, that offices and professions are often necessarily entrusted with persons little qualified for occupying them. One of the clergymen, and the principal physician of the place, are said to have originally been barbers. The United Provinces furnish very few military recruits; the rest are chiefly Germans, many of whom are said to have been kidnapped into the service.

All goods which are carried into or out of Batavia, are subject to duties which are levied at the bar at the entrance of the city. These, as well as the other taxes and imposts, are annually farmed out, generally to Chinese. The whole of them amount together, upon an average, to 32,000 six-dollars per month, or about 83,800*l.* sterling per annum. The important revenues arising from these import and export duties, &c. and the valuable productions which the country round it affords, the principal of which are pepper, rice, sugar, cotton, and indigo, might lead us to suppose, that Batavia, or rather the colony of Jaccatra, for that is the account in the books of the company, to which all that relates to Batavia is carried, would be adequate to its own support; yet this is far from being the case. Batavia is the metropolis of the Dutch East India possessions; it is the seat of their government; a large garrison is constantly maintained in it; most of the company's ships touch here, both outward and homeward bound; their cargoes are landed and shipped; all recruits are received, maintained, and paid here: in short, almost all the charges of the marine and military establishment of the company are carried to the account of Batavia, and of course a considerable balance appears every year against it. Formerly there used to be a considerable surplus after defraying all these charges; but in the year 1779, the charges exceeded the receipts by about 51,327*l.*

The coins current at Batavia are the following: viz. the milled Dutch gold ducat, the Japan gold coupang, the Spanish dollar or piastre, the milled silver ducatoon (which is the current coin of the company throughout their possessions, except on the continent of India), the unmilled ducatoon, the milled Batavia rupee, other rupees, half and quarter rupees. The smaller coins are skillings, twopenny pieces, and doits. Of the skillings there are two sorts: the old, worth 6 stivers; and the new, worth 7½. The old twopenny pieces pass for 2 stivers; the new, for 2½: the doits are stamped with the mark of the East India company, and are equal to a farthing in value.

Vol. III.

The following table shews the value, in sterling money, of the above coins, at the sterling value of 1*l.* francs per pound.

	<i>l.</i>	<i>s.</i>	<i>d.</i>
The old Japan gold coupang	24	0	—
The new ditto	14	8	—
The milled Dutch ducat	6	12	—
The silver milled ducatoon	4	0	—
The unmilled ditto	3	15	—
The Spanish dollar, from	3	3	—
to	3	6	—
The six-dollar	2	8	—
The Batavia rupee	1	10	—
Other rupees, about	1	7	—

Most merchants' goods are estimated at Batavia by "picols" of 125 pounds; or according to Ricard, 118½ pounds Amsterdam weight: and these picols are subdivided into 100 "cattis," each weighing 1½ pound. Rice and other grain are measured by "coyangs," which differ in weight; but when received by the company at Java, they must weigh 3,500 pounds. They are shipped to Batavia for 3,400 pounds, and landed there for 3,300 pounds; for the out-factories, they are dispatched for 3,200 pounds, unloaded for 3,100 pounds, and delivered for consumption at the out-factories for 3,000 pounds: so that every coyang loses 500 pounds in weight. This deficiency is an allowance made to the company's servants who have the management of the rice. Sugar is taken by "caassers" of 3 picols, or 375 pounds neat; the gross weight being about 400 or 405 pounds. The "ganting" is a small rice measure of 13½ pounds. Every bag of coffee shipped from Batavia to Holland weighs 252, and a bale of cinnamon 80 pounds.

The bay and harbour of Batavia are excellently adapted to the commercial navigation that is carried on at this place. A circular range of fifteen islands protects the road from any heavy swell, and renders it a safe place of anchorage for ships; and it is large enough to contain all those that double the cape of Good Hope, as well as the Chinese junks and other trading vessels of the country. The names of the islands are, Onrust, de Kuiper, which are the innermost, and within sight of the city; Purmerend, Engels Onrust, Rotterdam, Schiedam, Middleburg, Amsterdams, Horn, Harlem, Edam, Enshuizen, Alkmaar, Leyden, and Vader Smit. The company make use only of four of these islands, viz. Onrust, de Kuiper or Cooper's isle, Purmerend, and Edam; which see. At the boom, which crosses the bay below the town, all vessels pay toll. The sea-breeze, which rises every morning at ten, serves to bring vessels within the bar, and a land-breeze at night carries them out. The observatory formerly erected at Batavia is now neglected; but the Society of Arts and Sciences, founded under the administration of the governor-general De Klerk, still subsists. The 1st volume of its Memoirs was printed at Batavia in 1779. S. lat. 6° 10'. E. long. 106° 51' 15". Stavorinus's Voyages, vol. i. & vol. iii. Stamford's Account of Lord Macartney's Embassy to China, vol. i. p. 235, &c. Mod. Un. Hist. vols. vii & ix. See JAVA.

BATAVIA, a Settlement of America, in New York, at the head of Schoharie creek, about 39 miles from its mouth, and 38 south-west from Albany, and as far north-west of Esopus.

BATAVIA, a river of Asia, so called by the Dutch, situate in Carpentaria, on the coast of New Holland.

BATAVIAN REPUBLIC, an appellation given to the United Provinces after the conquest of them by the French, the exclusion of the stadholder, and the change of their form

of government. Towards the close of the year 1794, and the commencement of the following year, the French forces, favoured by the froil of winter, by the discontents that prevailed in the provinces, and the neglectful support afforded to the Dutch by the British troops, took possession of their principal towns; and on the 27th of January 1795, the provisional representatives of the people of Holland assembled, and chose Pieter Paulus for their president. On this occasion, several decrees were immediately passed for the future regulation of the government, and for the deposition of the stadtholder from all his offices. Among these decrees were the following: viz. the sovereignty of the Dutch people, and the declaration of the rights of man:—the abolition of the stadtholdership; as also of the offices of admiral and captain-general of the United Provinces, with all their appendages:—the release of the citizens and inhabitants of Holland from their oaths to the old constitution:—the suppression of the college of the deputy council, and that of the chamber of accounts; and the establishment in their room of a committee of public safety, a committee of military affairs, and a committee of finance:—and the recall of the commission of the deputies to the assembly calling itself the states-general. It was also decreed, that the commissioners of the assembly of the provisional representation of Holland should immediately begin their sittings in the hall of the ci-devant states-general, in order to advance the general interests of the people. A treaty of peace and alliance was concluded between the French and Batavian republics, at the Hague, May 16, 1795; in which the French stipulated to restore immediately all the conquered places and countries that belonged to the seven United Provinces; the frontier towns of the generality, such as Maastricht, Venlo, Breda, Bergen-op-Zoom, with their territories, excepted. It was also stipulated that the French, as well as the Batavians, should enjoy, without paying any tolls, the free navigation of the Scheldt, the Rhine, and the Meuse, and all their branches as far as the sea; that the Batavians should pay to the French the expences of the war which the latter had been compelled to make against the former; that the French republic acknowledged the independence and sovereignty of the Batavian; that an alliance offensive and defensive should be established between both republics; and that neither the French nor Batavians should conclude peace, or make any other treaty, in which both parties did not participate.

In 1796, the national convention of the Batavian republic made some considerable alterations in matters relating to religion. It was determined, that all the inhabitants of the republic were free to exercise without molestation any mode of public worship whatever to which their opinions might lead them; that there should be no established religion in the republic; that the use of bells in convoking persons to public worship, should be prohibited; and that Jews should be allowed to become citizens of the republic, and empowered to purchase lands in the same manner as other citizens. On the 11th of January 1797, the new plan of the constitution was discussed; and it was decreed, that the Batavian people are one and indivisible; that the sovereignty appertains to the whole Batavian people; and that the Batavian people shall elect representatives to exercise its sovereignty. It was also resolved, that all citizens born and resident in the republic, and twenty-one years of age, should be invested with the right of voting; and also strangers, after having resided within the republic six years successively. It was also resolved, that the republic should be divided into eleven departments. Towards the close of the year 1797, the French directory issued their mandate for a revolution.

The execution of this mandate was intrusted with Charles Le Croix, and the plan of operations for accomplishing it was concerted with the Dutch general Dazandels, who was an original mover, and principal agent in the revolution. Accordingly it was effected on the 22d of January 1798. This revolution gave birth to a new form of government in the Batavian republic, which was introduced and established by acts of violence. An assembly, termed by revolutionary despotism and military force, and assuming the name of the constituent assembly of the Batavian people, abolished those provincial divisions, and other administrations, that had been established under the convention; which was a constitution grounded on principles deemed more popular than those which formed the basis of that which was about to be presented when this revolution took place, and against which a formal protest had been previously made by forty members of the convention, when it was offered to the primary assemblies for their consideration. The people, wearied with continual agitations, and indeed incapable of effectual resistance, accepted this project formed on the model of the French constitution, as the best remedy against further convulsions; and thus Holland sunk for a while into the state of a dependent province, under the protection of Le Croix, the revolutionary delegate of the French directory. The principal articles that constituted the basis of this new government are the following: viz. —The abolition of the division into provinces:—Separation of church and state:—No corporation or society to have rules contrary to the laws of the state:—Exclusion from the right of voting of all the adherents of the Orange family:—The formation of a democratic representative government by means of a legislative body composed of two councils, and a provisional executive directory consisting of five members, having under it the agents of the executive power:—The formation of a new plan of finance, founded upon the relative means of the citizens:—The commissioners of the treasury are to be appointed by the executive power:—Those of the chamber of accounts by the legislative assembly:—The territory of the republic to be divided into a suitable number of departments; and accordingly, the nine provinces were divided into eight departments, the extent of which was measured by the population and the limits formed by the great rivers; these departments were again divided, each into ten circles; and each department was presumed to contain 235,000 inhabitants; and the general population of the republic was estimated at a million eight hundred and ninety-two thousand individuals:—A distinct division of three powers, the legislative, the executive, and the judiciary:—The right of individual petition to the citizens:—Revision of the constitution after the expiration of the fifth year:—The oath of hatred to the government of the stadtholder, federalism, aristocracy, and anarchy, to be taken by all the persons employed by the republic:—No power to have the right of interfering with the banks of circulation in the different towns of the republic:—Institutions for public instruction in arts and sciences:—And alliance with the French republic.

In the year 1801, a new constitution for the government of the Batavian republic, consisting of 108 articles, was introduced. This constitution abolishes the executive directory, and substitutes a late directory, consisting of twelve persons, one of whom goes out annually. The legislative body is to consist of 35 members. The territory of the republic is to be divided into eight departments, whose boundaries are to be the same with those of the old provinces. The allowance of the members of the legislative body is to be 4000 florins. They are to meet twice in the year, and

to fit from the 15th of April to the 1st of June, and from the 15th of October to the 15th of December. The government has the power of convoking them at pleasure. For further particulars, see HOLLAND, and UNITED PROVINCES. By the treaty of peace concluded at Amiens, March 27, 1802, the Batavian republic cedes and guarantees to his Britannic majesty, in full property and sovereignty, all the possessions and establishments in the island of Ceylon, which before the war belonged to the republic of the United Provinces, or to the Dutch East India company.

BATAVIENSIS, in *Entomology*, a species of *CRYPTOCEPHALUS*; the head, thorax, wing-veins, and legs of which are livid. Hornst. Sch. Berl. Naturf. Inhabits Java.

BATAVODURUM, in *Ancient Geography*, a town of the Batavi, in the island called after their name. According to Tacitus, the Romans had a bridge in this place, and the post was defended by a Roman legion, when the Germans, who resorted to the succour of Cerealis, were desirous of penetrating into the island; and here they were repulsed after great slaughter, and at length obliged to throw themselves precipitately into the river. Some have supposed that this town was the same with the modern *Duerstede*; but others conjecture that it was not on the same side of the river.

BATAVORUM INSULA, the island of the Batavi, was formed by the Vahalis or Waal to the south, and a branch of the Rhine to the north. This last branch, and also the Vahalis, rejoin afterwards, and form the Mosa or Meuse. According to Tacitus, the Rhine was divided at its entrance into Batavia into two rivers: one of which retained its name, and pursued its course through Germany, till it discharged itself into the ocean; the other, washing the coast of Gaul, with a broader and more gentle stream, was called Vahalis, which on its joining the Mosa, assumed its name. From this account it seems that the island of the Batavians was bounded by the Ocean, the Rhine, and the Vahalis. Cæsar extends it to the Mosa; but Pliny's account coincides with that of Tacitus. It appears, however, that this island was of greater extent in the time of Tacitus than in that of Cæsar; as Drusus, the father of Germanicus, had by a new canal conveyed the waters of the Rhine into the ocean at a considerable distance to the north of the former mouth of that river. It is not certainly known who were the first inhabitants of this island. Some historians say, that they had been removed by the Cimbri and Teutones, when they invaded the Roman territories; and it is not improbable that the prospect of a more commodious establishment might induce them to abandon a country which was constantly exposed to the inundations of the water that encompassed it. The Batavi, when driven from their own country by the Catti, took possession of it, and became a very powerful people. A part of this country still bears the name of *Batav*, formed from Batavi; and is probably the same with the ancient "Insula Batavorum." This name, however, is given only to the eastern part of the island, and is the same with that which has the river Leck to the north, and Vahal to the south, to the north of Nimeguen.

BATAVORUM Oppidum, *Batenbourg*, a town which seems to have been the *Batavodurum* of Ptolemy, but different from that of Tacitus. Ptolemy places it upon the Mosa, or Meuse; and the Batavodurum of Tacitus was more to the north upon the Rhine.

BATBERGEN, in *Geography*, a town of Germany, in the circle of Westphalia, and bishopric of Osnaburg.

BATCHAJOVE, a town of Asia, in Armenia, 90 miles south of Erivan.

BACHELOR. See BACHELOR.

BACHELOR's Buttons, in *Botany*. See LYCHNIS.

BACHELOR's Pear. See SOLANUM.

BACHELOR's River, in *Geography*. See BACHELORS.

BATCHURISCHKOI, a town of Russia, in the government of Archangel, on the east coast of the White Sea; 8 miles north of Archangel.

BATCOLE, or BAKUL, a sea-port on the coast of Malabar, in the peninsula of India, situate between Onore and Barcelore. The English had a factory here till 1670, when they were massacred by the natives. It was ceded to the British by the treaty of 1799. N. lat. $13^{\circ} 58'$. E. long. $74^{\circ} 37'$.

BATE, GEORGE, in *Biography*, born at Maid's Morton, in Buckinghamshire, in 1608, was sent to Oxford at the age of 14 years, where he soon distinguished himself by his diligence and application to study; and having made choice of medicine for his profession, he was admitted to practice as soon as he had taken his degree of bachelor in that line. In 1637 he was made doctor in medicine; and when Charles the First kept his court at Oxford, he was appointed his physician. Removing soon after to London, he was elected fellow of the college of physicians, and physician to the Charter-house; and conforming to the circumstances of the times, he soon obtained such favour with the ruling party in the state, that he was sent to Scotland, in 1651, in conjunction with Dr. Wright, to attend Oliver Cromwell, then confined there with an intermitting fever, and was appointed his first physician. This, however, did not prevent his being made physician to king Charles II. on his accession to the throne, and being elected fellow of the newly constituted Royal Society. These honours were procured him, Anthony Wood says, by a report industriously circulated by his friends, that he had hastened the death of the protector, by administering a deleterious medicine; a story, which, if believed, whatever reward it might otherwise have procured him, would never have placed him in a confidential post about the person of the sovereign. He died in 1668, and was buried in the chancel of All Saints church, at Kingston upon Thames, where a monument is erected to the memory of him and his wife, who died the year before. The only medical work in which he engaged, was in contributing a part towards a treatise "De Rachitide," published by Dr. Glisson in 1650. His prescriptions, collected by Shipton, an apothecary in London, were published some years after his death, under the title of "Pharmacopœia Batæana," and have passed through many editions. He published, in 1649, "Elenchus motuum nuperorum in Anglia, simul ac juris regii et parliamentarii, brevis narratio," 12mo. Paris. A second part of this work was printed at London, in 1661. In composing this, he was assisted by papers furnished by the chancellor Hyde. A third part appeared in 1676, written by Dr. Skinner. He is also said to be the author of the "Royal Apology, &c." 1647. Biog. Brit.

BATE, in *Ancient Geography*, a village or canton of Greece, in Attica, belonging to the tribe of Ægeides, where resided Abro, the commentator of Callias, who wrote concerning feasts and sacrifices, and Amynomachus, to whom Epicurus bequeathed his property. Steph. Byz.

BATE, or Bait, in *Geography*, one of the principal ports in a district of India, inhabited by a piratical tribe called Sangarians, on the south coast of the gulf of Cutch. The other port is ARAMROY.

BATEAH, a town of North America, in the province of Yucatan, 190 miles S.S.W. of Merida.

BATEAU, in *Navigation*, a particular kind of boat, very generally used upon the large rivers and lakes in Canada. Its bottom is perfectly flat, and each end very sharp

and exactly similar. The sides are about four feet high; and for the convenience of the rowers, four or five benches are laid across, and sometimes more, according to the length of the bateau. It is a heavy and awkward vessel both for rowing and sailing: but it is preferred to a boat with a keel for two very obvious reasons: first, because it draws less water while it carries a larger burthen; and secondly, because it is much safer in lakes or wide rivers, where storms are frequent. An oil-cloth awning may be thrown over the widest part of it, and supported by hoops similar to those of a waggon; and thus may be formed a very excellent cabin, which secures from the inclemency of the weather, and at the same time allows a view of the beauties of the scenery on each shore.

BATECUMBE, or **BADCOMBE**, **WILLIAM**, in *Biography*, an eminent mathematician, supposed by Pits (De Illust. Angl. Scriptor. An. 1420. n. 784.) to have flourished about the year 1420, in the reign of Henry V. He studied at Oxford, and made great proficiency in mathematics; which appears from his writings. It is not known where he died. He wrote "De Sphæra concavæ fabrica et usu," "De Sphæra solida," "De Operatione Astrolabii," and "Conclusiones Sophiæ." *Biog. Brit.*

BATELEUR, in *Ornithology*, a name given by Sonnini and others to **FALCO ECAUDATUS** of Latham, &c.

BATELLO, **ST.** in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, three miles north of Reggio.

BATEMAN BAY, lies on the south side of point Upright, on the east coast of New Holland, in which are three or four small islands. The north point is in S. lat. 35° 35'.

BATEMAN'S Drops, in *Pharmacy*, are the anodyne Balsam made with a weaker spirit, so that a larger dose can be taken; they are tinged with aniseed.

BATENBOURG, or **BATTENBURG**, in *Geography*, a town of the duchy of Gueldres, seated on the north side of the Meuse, nearly opposite to Ravelstein. N. lat. 50° 55'. E. long. 5° 35'.

BATANI, in *Ancient Geography*, a people of Asia, placed by Pliny and Solinus towards the Oxus and Bactriana.

BATENITES, a sect of apostates from Mahometanism, dispersed over several parts of the East, who professed the same abominable principles with the Ismaelians and Karmatians. The word signifies Esoteric, or people of inward or hidden light or knowledge. Sale's Koran, p. 186.

BATENKETOS, in *Astronomy*, a star about the third magnitude, in the constellation of CETUS.

BATES, **WILLIAM**, in *Biography*, an eminent non-conformist divine, was born in 1625, and educated at Cambridge, where he took his degree of B. A. in 1647. He afterwards became a celebrated preacher among the presbyterians in London. Upon the restoration, he was appointed chaplain to Charles II. and received a degree of doctor in divinity, by royal mandate from Cambridge. He was one of the commissioners at the Savoy conference for reviewing the liturgy, and one of the disputants on the side of the protestants against Dr. Pearson and other episcopalian. He took the oath required of non-conformists by the five-mile act, and was concerned in several unanimous efforts for effecting a comprehension of the dissenters by certain alterations and concessions. Moderate in his temper, and accomplished as a scholar, he was a fit person to be employed for such purposes; and he was always treated with respect by the members of the establishment. He was also much regarded by king William, and queen Mary frequently perused

his writings. Dr. Bates, towards the close of his life, resided at Hackney, where he died in 1699. His works, consisting chiefly of sermons and discourses, were collected after his death, and published in one volume folio. Besides these, a posthumous volume appeared in 8vo, consisting of "Sermons on the everlasting Rest of the Saints." He likewise edited a volume of the lives of eminent persons, written in Latin, and entitled, "Vitæ selectorum aliquot Virorum, qui doctrinâ, dignitate, aut pietate inclaruere," Lond. 1681, 4to. The style of Dr. Bates has been commended for its elegance; and he appears to have read many books in polite literature, as well as in theology. *Biog. Brit.*

BATES, **Josab**, Esq. late commissioner of customs, was born at Halifax, in Yorkshire, where he began his school education under the celebrated Dr. Ogden, with whom he remained till the doctor returned to reside at Cambridge. During this time he received the rudiments of music from Mr. Hartley, the organist of Rochdale. When Dr. Ogden quitted Halifax, Bates was removed to the school of Manchester, under Mr. Parnell; and it was there, as he has frequently told his friends, that the grand style of organ-playing, in which he so eminently excelled, was suggested to him by the performance of old Wainwright on the organ in the collegiate church. While he remained at Manchester, he had made such a proficiency in music as to be able frequently to officiate for his old master Hartley, when his avocations called him away from Rochdale.

Bates, on quitting that seminary, was removed to the foundation at Eton; but there his progress in music received a considerable check, and was in danger of being totally stopped; for it was contrary to the rules of that society for any of the boys on the foundation to be permitted the use of musical instruments. In this state of musical privation Bates remained some months, and had no other means of practising than by playing on imaginary keys on the table, which for a considerable time was his custom every day. At length, having by chance had an opportunity of touching the college organ, his talents for music were reported to Mr. George Graham, one of the assistant masters, who having a harpsichord, invited him to his rooms; and finding what an extraordinary performer he was, obtained permission for him to pursue his musical studies, accommodated him with the use of his harpsichord, and procured him liberty to play on the college organ at his leisure hours.

When he went to Cambridge, the vacancies for King's college were so few, that he was in danger of being superannuated, and was actually entered at Christ's college, where, while he was a member, two of the university scholarships became vacant, and he declared himself a candidate. It proved on this occasion a fortunate circumstance, that he had not gone off to King's; for as Dr. Heath and Mr. Keate, both of King's college, and his seniors, were candidates, the custom of that college would not have permitted a junior to become a candidate. But though he was now a member of Christ's, that circumstance did not prevent his being a candidate for a university scholarship; the examination for which is considered as the most severe of any classical examination in the university of Cambridge. Some of the most distinguished under-graduates were at this time candidates; and after an examination of several days, Zouch of Trinity, and Bates, were elected.

This success established his literary character in the university as high as his musical had been before: and soon after, as the term of superannuation was expired, a vacancy happening at King's, he was admitted a scholar, and

in three years, fellow. The regularity of his conduct during his scholarship, recommended him so much to provost Sumner, that he was appointed tutor to the college soon after his admission as fellow. While he was in this situation, among his private pupils he had not only students of his own college, but the present lord Bolton, and Mr. Coxe the traveller, both then scholars of King's, were his private pupils; as was the Hon. William Augustus Montagu of Trinity college, second son of the earl of Sandwich. This produced a connexion with that nobleman, which ended in his lordship's tempting him to resign his fellowship, and reside with him at the admiralty in the capacity of private secretary.

Few dilettanti musicians have ever acquired or deserved more fame for their knowledge in music, judgment, and experience in its effects, and abilities in conducting a complete orchestra and numerous band of fingers, than Mr. Bates, who, at the university of Cambridge, distinguished himself as a fine performer on the harpsichord, as well as a zealous votary of the works of Handel; and as long as he remained at college, he performed the part of a Coryphæus at all public and private concerts. It may perhaps not be thought unworthy of notice here, that at this time (about the middle of the last century), the university of Cambridge was in possession of four very extraordinary dilettanti musicians: Dr. Smith, master of Trinity college, for the theory of sound; the Rev. Thomas Twining, an admirable performer and leader on the violin, and an excellent judge of every species of music; the late worthy and ingenious Mr. Lobb of Peterhouse, the most correct and certain *Sight's* man on the harpsichord or organ with whose performance we have been acquainted; and Mr. Bates for his masterly performance on keyed instruments, and abilities in conducting a band. There being at this time no very able professor in the university, these gentlemen regulated and performed at all public and private concerts during their residence in college.

No one stood higher in character, or was more courted in society, while at Cambridge, by persons of all ages than Mr. Bates; in particular by the late Dr. Smith, the master of Trinity college, with whom he spent most of his evenings, and who, at his death, left him a legacy.

Before he quitted the university, an organ was built for the church of his native place, Halifax; and determining that it should be opened with éclat, he, for the first time that any oratorio had been performed north of Trent, attempted the *Messiah*. With the assistance of the Rev. Mr. Allott, of Kirkheaton, who had trained up the country people in his parish to sing choruses in a very superior style, and with the addition of Bates's own exertions, with the fingers of Halifax, the choruses were performed with a precision that astonished every one; and it was universally acknowledged by the best judges, that the *Messiah* had never been so well performed. The first violin, on this occasion, was performed by the celebrated Dr. Herschel, the astronomer; and his profession being then music, he was immediately elected organist.

It was the success of this undertaking that inspired the late commissioner with the idea of rescuing the compositions of old masters from oblivion, by having them executed by a numerous and select band of vocal and instrumental performers; and after being settled in London as private secretary to lord Sandwich, he had an opportunity of communicating his plan to persons of the first distinction, and the establishment of the *Concert of Ancient Music* in Tottenham street was the consequence, being formed and executed entirely under Mr. Bates's direction: and as many of the works of Handel, which had not been performed for many years, and never so well as at this establishment, were revived, the

number of that truly great, and often sublime, composer's admirers was much increased.

His majesty, a constant and steady patron and protector of the works of Handel, soon after the establishment of this concert, graciously condescended to become a subscriber; and together with her majesty and the princesses, constantly to attend the several performances. The nobility and gentry, who were enrolled among the original subscribers to this respectable institution, have been likewise steady in their patronage and attendance. And it is now (1802), from the splendor and celebrity of its admirable performances, in higher public favour, than at any former period of its establishment.

After remaining some years with the earl of Sandwich at the admiralty, Mr. Bates was appointed commissioner of the victualling office; and soon after, he married his celebrated pupil, Miss Harrop, who had been educated under his eye from his first arrival in London; and whose seraphic voice, and disposition for music, he so highly cultivated, as to render her one of the most enchanting singers which this or perhaps any country ever produced.

The victualling office on Tower hill now became the resort of persons of the highest rank; and at his residence there, was planned that most stupendous musical performance, the *COMMEMORATION OF HANDEL* in Westminster abbey and the Pantheon, which was conducted by Mr. Bates in a manner never to be forgotten by those who had the happiness of being present. The great splendor and success of this *COMMEMORATION* will unite the name of commissioner Bates with the renown of *HANDEL*, as long as such a memorable event shall remain in the records of the musical art. And the performance of Mrs. Bates, particularly in the pathetic songs of Handel, has rendered it so difficult for her successor at the concert of ancient music, to satisfy the old subscribers in such songs as she used to perform there, that something will always seem wanting to complete their happiness.

Soon after the commemoration, Mr. Bates was promoted to a seat at the board of customs; but previous to his quitting the victualling-office, having officially experienced the difficulties which the capital of the kingdom often labours under for want of flour, he projected the plan of the *Allion Mills*; on the success of which he was so sanguine, that he vested his whole fortune, and even that of his wife, in the capital stock of that company, to the amount of 10,000*l*. By the conflagration which happened to this building, he was completely ruined. His whole fortune was not only vested in the company, but his credit for a large part of the stock in hand, which was all consumed by the fire; so that he was totally bereaved of the means of making any provision for his family, and of guarding against the vicissitudes to which humanity is subject. He submitted to this event with dignity and fortitude; but the circumstance of having involved his wife in the ruin, and sacrificed her professional acquaintances without her approbation, preyed so continually on his mind, as at length to produce a complaint in his chest, which finally proved fatal, and brought him to the grave, the 8th of June 1799, at the age of 59.

BATESON, THOMAS, an English Madrigalist of the beginning of the seventeenth century, not devoid of merit as a vocal composer. He was organist of the cathedral of Chester in 1600. *Ant. Wood* says, that he was a person esteemed very eminent in his profession, especially after the publication of his English madrigals to three, four, five, and six voices. About 1618, he became organist and master of the children of the cathedral church of the Blessed Trinity in Dublin; and in the university of that city, he obtained the degree of bachelor of music.

BAT-FOWLING, a method of catching birds in the night, by lighting some straw or torches near the place where they are at roost; for, upon beating them up, they fly to the flames, where being amazed they are easily caught in nets, or beat down with buikes fixed to the end of poles, &c.

BATGAN, or **D'HATGAN**, in *Geography*, a city of Hindoostan, situate in the extensive plain of the kingdom of Nepal or Napaul, to the east of Lelit Pattan; and 10 miles south of Catmandu, the capital of Nepal. It contains about 12,000 families, extends towards the east to the distance of five or six days' journey, and borders upon another nation, also independent, called Ciratas, who profess no religion. In 1769, the king of Gorka took possession by force of the city of Batgan. See Father Giuseppe's account of the kingdom of Nepal in Asiatic Researches, vol. ii. p. 308. N. lat. 28°. E. long. 85° 12'.

BATH, a city of Somersetshire in England, is situated in N. lat. 51° 22' 30", W. long. 2° 21' 30", at the distance of 107 miles west from London, and 12 east of Bristol. This ancient and elegant city is singularly favoured by nature and art, whose joint co-operations have conspired to give it importance and celebrity. The beauty and peculiarity of its situation are perhaps unequalled by any town in England. Planted originally in the bottom of a deep and narrow valley, where its hot waters boil up, it continued for ages to be confined to the dimensions which the Romans had first marked out; and till within the last century, the ancient Roman walls (inclosing a space of about fifty acres) formed the boundaries of Bath. But the fashion and celebrity which it latterly obtained, induced many builders and speculators to extend the streets in all directions, by additional houses, which were instantly occupied upon completion. Built of the fine *oolite*, or granulated egg-like freestone, which forms the basis of the surrounding hills, the houses are remarkable for their exterior neatness and splendour; and being raised over the sides of the broad acclivity of Lansdown (which rises to the north), in irregular groups of streets, squares, parades, circuses, and crescents, they present to the eye an appearance equally singular, magnificent, and beautiful. Nothing, indeed, can be more picturesque than the views of this city from various stations on the surrounding eminences; where houses rise above houses in progressive order, and the more elevated seem to look down with proud superiority on the no less elegant and extensive structures below.

BATH, Ancient History of. Various names have been given to this city at different periods. Its British appellation was *Caer-Badon*. In Latin, it was called *Aquæ Solis*, *Fontes Caldi*, *Achamannum*, *Therma*, *Badonia*, &c.; and in Saxon, *Aecmannes-ecastre*, *Aecmannes-bepi*, *Leabædun*, &c. Most of these names refer to its situation, and its springs or baths. The origin of this place as a settlement or town, is lost in the lapse of ages; and its early history is enveloped in legendary tales and monkish fables. The strange story of Bladud and his leprous pigs is discredited by all rational thinkers, though it formed a part of the creed of the Bath citizens only within the last fifty years. "But the present generation (observes Mr. Warner) are wiser and more prudent than their fathers, and rather attentive to the value of the fragments of their origin, have at length formed the happy enquiry of their discovery, in the agreeable contemplation of the large rents which they throw into the common stocks."

But Bath was one of the principal, if not the most considerable of the Roman stations in England, is satisfactorily proved by the many architectural and military antiquities which have been found within its precincts. It is probable that

if Bath was not originally built by the Romans, it was at least reduced under their power, and embellished by their arts, as early as the middle of the first century; when, in the reign of the emperor Claudius, according to Tacitus, about the year 44, the western and south-western parts of this island were completely subdued by Flavius Vespasian. Attracted by the medicinal and warm springs which they found here, and which afforded every means of indulging in that prime enjoyment of Roman luxury, the bath, the Roman soldiers fixed in this place one of their principal stations. "*Aquæ Solis*," the name by which they designated this delightful residence, was soon established as a colony; and of course became entitled to the privilege, which all the Roman colonies enjoyed, of minting its own money. It is to be conjectured, also, that a military forge, or college of armourers, was erected here for the fabrication of legionary arms, under the authority of a Roman government. In the reign of Adrian, about A. D. 118, the first detachment of the second legion, which had been stationed here, was joined by a division of the sixth; and in that of Severus, a part of the twentieth legion, removed from Devana, or Chester, had its station in *Aquæ Solis*, which was then become the most capital city in Roman Britain, and the principal, if not the only, place in this part of the island, for preparing the legionary arms and ensigns. The form of the city then constructed, according to that usually affected by the Romans, approached to a parallelogram, swelling out on one side, so as to describe an outline somewhat pentagonal, and stretching in length, from east to west, about 400 yards, and 380 yards in the broadest part from north to south. The wall, which rose upon the outline of the settlement, appears, from subsequent discoveries, to have been twenty feet above ground in height, and in thickness sixteen feet at the base, and eight at the summit. It was strengthened with five towers, rising at the angles; and had four portæ, or entrances, facing the cardinal points, which were connected together by two grand streets, dividing the city into four parts, and intersecting each other at the centre.

The place thus fortified and strengthened for security, was next adorned with houses for the officers, temples, and those magnificent baths, the remains of which were discovered, in digging to a considerable depth, in the year 1755. These baths were seated near the centre of the city, betwixt the north and south gates, on the eastern side of the great fosse-road. The sudatories, tympanum, fluted-columns, cornices, pilasters, and sculptured ornaments, found here, prove that the buildings were constructed from elegant designs, and of similar characters to some structures described by Pliny and Vitruvius. Many altars have also been found here bearing the inscriptions of *Dææ Sulini Minervæ*, *Dææ Sulinis*, &c. concerning which many conjectures have been adduced. Mr. Warner affirms the goddess *Sulinis* to be a local deity; Mr. Lysons asserts that the name is of Gothic origin; whilst Mr. Whitaker more appropriately and happily explains it to be the British characteristic appellation for *Minerva* as the tutelary goddess of medicine, deriving her influence immediately from the sun. This great dispenser of heat was denominated *Sul* in the Celtic language. The ancient baths occupied a space measuring 240 feet in length from east to west, and 120 feet at the broadest part from north to south. (These baths, and remaining fragments, have been particularly described and illustrated by governor Powel and Mr. Warner, in publications expressly on the subject; and the fragments are represented and described by Mr. S. Lysons in a volume lately published.)

The Romans being established here, constructed four of their great military roads to communicate between this place
(*Aquæ*

(Aque Solis) and the stations of Durocorinium (Cirencester), Verulacio (Heddington), Iffsalis (Isheden), and Abone (Aurebury). The conquering Romans having enjoyed the possession of Bath and England for nearly four centuries, at length left the whole island to the possession of the Britons, who were afterwards subjugated by the hardy Saxons. It was not till the year 577 that Aque Solis fell into the hands of these destroying conquerors, who under the command of Ceaulin and Cuthwin, overcame Commail, Cardidan, and Farinmail, the three British kings of Gloucester, Cirencester, and Bath, at a place called Dyham, eight miles from the latter place, and took possession of their respective dominions. Bath now received the privileges of a Saxon burg; had its Gerefa or judiciary appointed to it, who presided in the monthly meeting of its citizens, called the burgemote or solemote; councils instituted for the regulation of the police, and administration of the laws within the burg. Bath was afterwards taken by Offa king of Mercia; and during the civil wars and Danish invasions which prevailed in the eighth century, it was torn to pieces and nearly exterminated as a town. During the brilliant reign of Athelstan, this place again rose to consequence; and a mint was established here by that monarch, who also gave several large donations of estates to Offa's abbey. King Edgar was crowned and inaugurated here, and testified his regard for the place by granting it several privileges. The inhabitants seem to have been fully sensible of the favours conferred on them by this monarch; and according to the statements of Leland they prayed for several centuries "in all their ceremonies, for the king's soule; and at Whitfuntide," he states, "there is a king elected every year of the townes men, in the joyful remembrance of king Edgar, and the privileges given to the town by him." During the Danish dominion in England, the mints of Bath continued to be worked, and several coins of Canute the Great, struck here, are still remaining in some select cabinets.

The Norman conquest had produced much general evil to the country; and Bath, with several other cities, experienced, in consequence of it, great deterioration. But this was partial and light, compared to the miseries which happened to it in Rufus's reign; when in the insurrection raised by Odo bishop of Bayeux, Geoffrey bishop of Constance, and Robert de Mowbray; the two latter took the place by assault, and, in the spirit of the times, delivered it over to plunder and burning.

Bath was indebted for its restoration to John de Villola; who purchased it of Rufus, in 1090, for 520 marks, and obtained permission to remove the pontifical seat from Wells hither. He rebuilt the city, erected a new monastery upon the ruins of the old one, and united the bishopric to this institution. Thus reinstated, Bath gradually increased its monastic possessions, in consequence of the munificence of monarchs and private persons; but the sweeping dissolution of Henry VIII. drove the monks from its monastery, when the abbey-house, with its lands, &c. was granted to private individuals.

The citizens of Bath returned Members to the English parliament as early as the 26th of Edw. I. and writs were regularly sent them for the same purpose every time parliament was summoned to meet. But as these privileges were attended with heavy charges on the burgesses, who generally paid the expences of their members, the city was not represented during the 1st and 2d years of Edward II. It now sends two members, who are elected by the body corporate, consisting of thirty-one persons. The government of Bath was originally vested in a sheriff; and the first that appears to have borne this office was Ælfred, who

is said to have been a great benefactor to the city, and died A. D. 907. It had afterwards a provost or bailiff. Its first charters were confirmed by king Edward III., Richard II., Henry V., and Henry VI. Queen Elizabeth, in the 32d year of her reign, granted the city a new charter, declaring it to be a sole city of itself, and the citizens to be a body corporate and politic, by the name of mayors, aldermen, and citizens of the city of Bath. This charter was renewed in 1794, when two additional franchises were granted the citizens; and under that charter the corporation derive their authority, power, and rights.

The commerce of this city, abstracted from the expences of fashionable company, is inconsiderable, nor is there any manufactory deserving particular notice. Bath was formerly distinguished for its clothing trade; and at the time of the restoration, it is said, there were no less than sixty broad-cloth looms used in the parish of St. Michael.

The river Avon, which winds round the southern part of this city, was made navigable by an act of parliament in the 10th of queen Anne; and the first barge, laden with deals, pig-lead, and meal, was brought here December 15th 1727.

In the earlier part of the civil wars, this city was garrisoned for Charles I. and the sum of 7000*l.* is said to have been expended on its fortifications; notwithstanding which, it quickly surrendered to the enemy, and was made one of the principal posts for the parliament's forces. Sir William Waller lay here for a considerable time with his whole army, making sallies into the country, and inviting together all the disaffected from the neighbouring clothing towns and villages. But after the battle of Roundway-down, July 13 1643, in which Waller was defeated, and the withdrawalment of the garrison for the reinforcement of Bristol, the king's troops took possession of the city.

Having stated a few particulars relating to the early history of Bath, we proceed to a brief description of its principal public structures, and other prominent objects which characterize this fashionable place.

The Public Baths are four in number, besides two private baths. These are all constructed with particular attention to the convenience and accomodation of invalid bathers; and the laws and regulations are very equitable and fair. (For an analysis of the hot waters of Bath, and an account of their medicinal powers, vide Dr. Gibbs's Treatise on the Bath Waters.)

The King's Bath is supposed to be so denominated from some of the Saxon kings having made this city their residence. It is situated to the west of the abbey church, and forms a parallelogram, 65 feet 10 inches in length, and 40 feet 10 inches in breadth; the bottom of which is 12 feet below the surface of the ground. The spring or main source is from the centre, which is covered with a large leaden reservoir, to restrain its rapid motion, and to disperse the water more equally, both for bathing and drinking. There are also two commodious rooms with pipes, fire-places, and other conveniences for the bathers. This bath fills in nine hours.

The Queen's Bath, which receives its waters from the former, forms a square of about 25 feet in diameter. *The Cross Bath* forms a handsome termination to Bath-street, and is a very elegant building, constructed after a plan of Mr. Baldwin's; its shape is triangular. *The Hot Bath* is erected to the south-west of the latter, and is so called from the superior heat of its water; this also forms a parallelogram, and is perfectly convenient with respect to an open bath, private baths, dry-pump, and dressing rooms. Certain regulations are prescribed respecting these baths and the persons belonging to them; as well as particular fees for every process of bathing, pumping, &c. A building to the King's Bath,

in Stall-Street, are some new private baths, which were erected by Mr. Baldwin in 1783. These baths belong to the corporation. There are also the private baths, called the duke of Kingston's, or the abbey baths, belonging to lord Newark, and in the occupation of Mr. Sloper. See *BATH WATER*.

BATH, Public Buildings. The Guildhall is a very handsome structure, built after a design of Mr. Baldwin, and contains a number of useful and convenient rooms for public business. In the common-council room, one of the most elegant of the kind in England, are portraits of the king and queen, the late prince and princess of Wales, and the late earls Chatham and Camden. The Pump-room was constructed, by the same architect, in the year 1796: its length is 85 feet, including the recesses at the ends; in breadth 46 feet, and 34 feet in height. The inside is set round with Corinthian three-quarter columns; and lighted by a range of large windows below, and of lesser ones above. Here is a marble statue of Richard Nash Esq. the arbiter elegantiarum of Bath; a gentleman to whom this city is principally indebted for its fashionable celebrity. The pump is held under a beneficial lease from the corporation for three years, the rent being 800 guineas, exclusive of taxes; which, however, is sufficiently low to enable the lessee to lay up 1200l. or 1500l. during the term. Most of the elegance of street-building in Bath is owing to the late Mr. Wood; who commenced his operations with spirit, and conducted them with taste. To him the city is indebted for Queen-square; the northern side of which presents a chaste and neat range of structures, decorated with all the ornaments of the Corinthian order.

The Circus is of his designing; here the houses partake of the three orders, Doric, Ionic, and Corinthian, highly ornamented. To the grandeur of his designs, the North and South Parades bear ample testimony; as do several streets stretching to the northward of the old city, which strongly mark his judgment and execution. Subsequent architects have followed Mr. Wood's example, and hence arises a profusion of new squares, crescents, parades, and streets; thus increasing Bath to six times its original size; and the beauty of the city is equal to its extent.

The new Assembly Rooms are the most elegant of the kind in Europe; these were built by Mr. John Wood in 1771, at an expense of 20,000l. The ball-room is 105 feet 8 inches long, 42 feet 8 inches wide, and 42 feet 6 inches high; the other parts of the building are composed of the octagon room, the tea-room, and the card-room, all of equal beauty. The regulations to preserve order and decorum in these rooms are simple and satisfactory. The lower rooms, near the north parade, have a convenient suite of apartments appropriated to the elegance of the place; and here are to be seen the original regulations by Mr. Nash, which he wrote for the purpose of reducing politeness and urbanity to a system. A neat small Theatre was erected in Orchard-street by the late John Palmer Esq. who obtained a patent for dramatic entertainments in 1768; and here plays are performed on Tuesdays, Thursdays, and Saturdays. Sydney gardens are laid out in a very pleasant and elegant style, for the purpose of evening promenades: where galas and public music and singing are given similar to the entertainments at Vauxhall gardens of London.

Hospitals, &c. Buildings and institutions of this nature form a striking feature of Bath; and no place in the realm, according to its size, exhibits so many foundations for the extermination of disease and wretchedness, for the support of the poor, and the instruction of the ignorant. The general hospital, from

the munificence of its plan, is an institution open for all the sick poor in the united kingdom, who labour under diseases to which the hot waters of Bath particularly apply, with an exception to those persons inhabiting the city, who have the waters at their own houses for a small expense. Mr. Nash had the honour of suggesting the idea for its foundation, in 1715, and the first stone was laid in 1738. St. John's hospital, originally founded by Reginald Fitz-Joselin in 1180, and the chapel attached to it, stand near the cross bath, and were built in 1728, upon the site of an old structure for the accommodation of six infirm men and women. St. Catharine's hospital, called also the Black alms and Bimberries, is another asylum for ten poor persons. Bellot's hospital entertains twelve poor men and women, who have each an apartment, the liberty of bathing, and a small weekly allowance. The Bath city Dispensary and asylum, is equally open to the inhabitants and strangers in cases of physical and surgical emergency; and is a most excellent institution. The Casualty hospital is appropriated to paupers who have been injured by accidents. The Puerperal, or child bed charity, is another benevolent institution, whose objects are explained by its name.

Bath has, besides these establishments, a public grammar school, charity and Sunday schools, with many humane and scientific societies. The principal of these are, the strangers friend society, and the Bath and west of England society. The first is established and conducted on the most benevolent principles of universal philanthropy; and the only recommendation for relief, is a sufficient proof of evident distress. The second was established by Mr. Edmund Rack, in 1777, for the encouragement of agriculture, arts, manufactures, and commerce; and from the judicious management of its founder, and late secretary Mr. W. Matthews, it has acquired some celebrity, and proved of extensive utility. The philosophical society was established in the year 1799, by some respectable literary characters at Bath, upon a plan somewhat similar to that at Manchester, for the promotion of science and the diffusion of knowledge.

Parishes. Bath is divided into the parishes of St. Peter and St. Paul, St. James, St. Michael, and Walcot. Bathwick, though connected by Pulteney bridge, and consisting of a great number of handsome houses, is out of the jurisdiction of the city. Each of these parishes has its church; and in that of Walcot are several chapels of ease. Of these, the principal is the Abbey Church, which presents a noble specimen of English architecture. It is built in the form of a cross, from the centre of which rises a tower 162 feet high, ornamented with beautiful light perforated battlements. The length of the body, from east to west, is 210 feet, from north to south, 126; and the breadth of the body and side aisles, 72 feet. The grand entrance at the west is through a noble arched doorway; and the chaste uniformity, proportion, and harmony in the structure of the interior of this stately building, powerfully arrests the attention of the beholder. The west window is of extreme richness, and the whole of this front displays a representation of allegorical carving, not usually met with. The roof, consisting of two parts, the nave and the choir, is equally remarkable; the ribs which compose its tracery being the only solid work, the intermediate spaces having been originally left open, and afterwards filled up with lath and plaster. The windows are all large, of admirable and nearly uniform construction; this has occasioned the church to be called "The Lantern of England." A profusion of marble monuments ornament, or rather crowd up, the inside; among which may be noticed those of bishop Montague, Quin, beau Nash, lady Miller, and sir William

William Draper. The vestry contains a small library, founded by bishop Lake. Oliver King, bishop of Bath and Wells, in the time of Henry VII. undertook this building we have described; but by a neglect of his four successors, cardinals Adrian and Wolsey, and bishops Clark and Knight, the undertaking was so dilapidated, that at the dissolution it was proffered to the citizens for 500 marks. They refusing the purchase, under an idea of offending the king, the glass, iron, bells, and lead were stripped from it, and sold at a foreign market. Thus it continued in a ruinous state till the reign of queen Elizabeth, when subscriptions were set on foot to restore it; and Thomas Bellot Esq. steward of her household, repaired the choir for divine service; bishop Montague, in the next reign, at the expence of 1000l., completely restored the whole to its former state: and with the assistance of several munificent noblemen and gentlemen, the abbey of Bath became again a consecrated temple to divine worship and a grand ornament to the city.

St. James's church was erected in 1768, and is a freestone structure, with a square tower rising at the west end, containing eight musical bells. St. Michael's church was begun in 1734, and is injudiciously situated in the middle of a street. Walecot church, dedicated to St. Swithin, is a neat modern structure, rebuilt in 1780. In this parish are four chapels of ease, and a church for the use of the poor: of these, Christ's church was built by voluntary subscription for the use above mentioned; and the whole area is therefore appropriated solely to accommodate the poorer class of inhabitants. There are also in Bath other chapels and meeting-houses for divine service: the Octagon and Laura chapels are of the established religion. The Unitarians, Quakers, Baptists, Methodists, Moravians, and Roman Catholics have each a place for divine worship.

Bath is furnished with 438 lodging-houses, and 19 boarding-houses, where individuals and families are accommodated with every domestic convenience during the winter, which is the fashionable season. The shops of bath are particularly splendid, and its libraries are numerous and respectable.

Civil Government. The judicial business of the city is transacted in the guildhall, where quarter-sessions, a court of record, and a court of requests are held. The corporation consists of a mayor, ten aldermen, two sheriffs, and eighteen common-council men, besides town-clerk, constables, &c. The principal markets are kept on Mondays and Saturdays.

For further particulars concerning the history and description of this city and its environs, see Warner's History of Bath, 4to. and the Bath guides published at this place.

BATH Water. Bath has been long celebrated for its thermal waters. There are three principal sources of the water; called the King's bath, the Cross bath, and the Hot bath. The supply of water is abundant and invariable. The temperature of the hottest of these is uniformly 116°, when fresh drawn, and of the coldest 112°; and no variety of season appears in any degree to influence this temperature. By some accurate observations that were made on the heat of Bath and Bristol water, by Mr. Canton, it appears, that a Fahrenheit's thermometer held in the stream from the common pump of the king's bath after pumping about a quarter of an hour, was raised to 112°. The stream from the common pump of the hot bath raised it to 114½°. At the pump of the cross bath it stood at 110°; the heat of the shaded air at noon being 66°, and of common water exposed to it 61°. And the Bristol water raised the thermometer to 76°, whilst in common water exposed to the shaded air it stood at 62°. Phil. Transf. vol. lvii. N° 22.

The analysis of Bath water has been the cause of much controversy among chemists, but it seems now to be well understood. To the taste it is neither brisk, nor acid, nor alkaline, nor saline, nor sulphureous, but simply hot and chalybeate; and it is truly remarkable that the chalybeate taste is entirely lost as soon as the water cools, before any sensible precipitation of the iron takes place. The actual quantity of the iron is so minute as never to have been estimated with any accuracy: probably a quarter of a grain in a gallon is an ample allowance, a quantity so small as only to be perceptible to the taste when fresh drawn and hot. Bath water contains no other ingredients of any importance. It is hard, and holds some calcareous earth in solution, and (as Dr. Gibbs has discovered) a portion of silex. It is perfectly free from sulphur. A considerable quantity of azotic gas rises from the earth along with the water, and a certain portion is held by it in solution or rather weak affinity. Of carbonic acid it only contains about $\frac{1}{25}$ of its bulk.

The diseases for which the Bath water has been recommended are very numerous. It has long enjoyed a high celebrity in the cure or relief of gout, chiefly of the atonic kind; of rheumatism; paralysis, especially that partial palsy of the limbs induced by rheumatism; and diseases of the urinary organs. When drank fresh from the spring (the only time when it possesses any peculiar virtues), it sometimes raises the pulse, causes the face to flush, and heats the body very considerably; and hence there are many invalids who cannot bear its operation, or who must be gradually accustomed to it. This heating effect, however, is by no means constant or universal. It often produces a costive state of body, and generally keeps the skin pervious and easily perspirable. Its use as a hot, warm, or tepid bath, is full as extensive and probably important as when taken internally. It has been thought by many that the practice of drinking our Bath waters in Somersetshire is not very ancient, and that their ancient use was in bathing; but Dr. Freind endeavours to shew the internal use of those waters to have been very early. Dr. Guidot, in whose time this usage revived, and who has given us an historical narrative of these waters, goes no higher for their internal use than the latter end of the sixteenth century. But they appear to have been in use in the thirteenth century. Gilbert, surnamed Angliens, who, according to Bayle, lived in 1210, in the reign of king John, or more probably in that of Edward I. mentions a person cured of a leucoplegma attended with a swelling, &c. by the sulphureous baths: which Dr. Freind understands of the Bath waters; and that the cure was wrought by drinking, not bathing, which had been improper in such a case.

Dr. Musgrave makes it probable, that they were resorted to in the time of Geta; there being still the remains of a statue erected to that general, in gratitude for some benefactions which he had conferred on the place. Some pretend that these waters were in use 800 years before Christ. Phil. Transf. N° 49. 346.

The two stated seasons for drinking the Bath waters are spring and fall; though they may be used whenever they are found necessary.

BATH, in Geography, a river of Africa, in the kingdom of Fez, which rises in mount Atlas; and joining the Suba or Sebu, flows into the ocean north of Mahmore.

BATA, a county of Virginia, in North America, about 60 miles long and 50 broad, bounded on the east by the county of Augusta; and noted for its medicinal springs, which are hot and cold, near the foot of Jackson's mountain.

BATH, a township of Lincoln county, in the district of Maine, in America, containing 949 inhabitants. It lies on

the west side of Kennebeck river, about 13 miles from Wiscasset, 60 N.E. from Portland, 32 from Hallowell, and 165 N.E. from Boiton. N. lat. $43^{\circ} 49'$.

BATH, a thriving town, in Berkley county, in Virginia, seated at the foot of the warm-spring mountain. The springs in the vicinity of this town, though less efficacious than the warm springs in Bath county, draw upwards of 1000 people here, during summer, from various parts of the United States. The country in the environs is agreeably diversified with hills and valleys; the soil rich and well cultivated; 269 miles S.W. from Philadelphia.

BATH, a township of America, in Grafton county, New Hampshire, containing 493 inhabitants; and lying on the east bank of Connecticut river; 35 miles N.E. by N. from Dartmouth college, and 97 N.W. from Portsmouth.

BATH, or *Port Bath*, an ancient town in Hyde county, North Carolina, on the north side of Tar river, about 24 miles from Pamlico sound, 61 S. by W. from Edenton, and in the port of entry on Tar river. It contains about 12 houses, and is declining. N. lat. $35^{\circ} 31'$. W. long. $77^{\circ} 15'$.

BATH, a village in the county of Rensselaer, New York, pleasantly seated on the east bank of Hudson river, nearly opposite to the city of Albany, at the head of Sloop navigation. A mineral spring has been discovered in this place, and a commodious bathing house has been erected, at a considerable expence, containing hot, cold, and shower baths.

BATH, a thriving post-town in Steuben county, New York, containing about 50 houses, situate on the north bank of Conhocton creek, a northern head-water of Tioga river, 42 miles south-east from Williamsburg, 120 from Niagara, and 221 west from Hudson city. N. lat. $42^{\circ} 15'$. W. long. $77^{\circ} 10'$.

BATH, a village in the eastern parish of St. Thomas, in the island of Jamaica. It owes its rise and name to a hot spring near it, which is said to be very efficacious in the cure of the dry belly-ache. The sulphureous water flows from a rocky mountain about a mile distant, and is so hot that the hand cannot be held in it.

BATH, BALNEUM, a convenient receptacle of water for persons to wash or plunge in, either for health or pleasure. Baths are either natural or artificial. Natural, again, are either hot or cold.

BATHS, Natural, hot and cold. See *Mineral Waters*.

BATHS, Artificial or Medicated. The very accurate imitations of most of the mineral waters for the purpose of drinking which are now met with, have induced some ingenious artists to extend the imitation to larger quantities of water sufficient for the purpose of bathing. The method of performing each will be explained under the article of *WATERS, Mineral*.

Of artificial baths some are aqueous, others vaporous, others dry, &c.

BATHS, Aqueous, are those prepared from common plants and other substances of emollient, resolvent, and nervous kinds. *Aqueous Baths* sometimes consist of milk and emollient herbs, with rose-water, &c. when the design is to humectate; at other times of bran and water, when the design is only to cleanse; sometimes again they are made of a decoction of roots and plants, with an addition of spirit of wine, when a person bathes for a great pain or tumor, &c.

In *Vapour Baths*, the fume or steam of some decoction is received upon the body to promote a perspiration. These are also by some called *Balnea Lævonica*.

Vapour Baths are, when the patient is not plunged into what is prepared for the bath, but only receives its steam

upon those parts of his body which require it: as in some distempers of the fundament and womb, where the patient sits and receives the fumes of some proper fomentation, &c. Mr. James Playfair has published "A Method of constructing Vapour Baths," so as to render them of small expence, and of commodious use in private families." The principles on which this method is founded are, that in the vapour bath the water being applied, not in the state of steam, but of solution in air, a much less quantity of the heated fluid than that usually applied will suffice, provided the heat of the inclosed air can be maintained in a sufficient degree; and that dense substances, especially metallic ones, being the greatest conductors of heat, are to be avoided in the construction of the vessel containing the vapours, and the lightest and most non-conducting materials used instead of them. The whole apparatus for the vapour-bath is, therefore, reduced to a tin boiler, tin pipes wrapped in flannel, and a deal box, with a cotton cover, for the reception of the body and circulation of the vapour.

To these may be added the bagnio, where people are made to sweat by the heat of a room, and pouring on of hot water; after which they generally go into a hot bath, or bagnio. See *BATHING*.

BATHS, Dry, are those made of ashes, salt, sand, shreds of leather, and the like.

The ancients had divers ways of sweating by a dry heat; as by the means of a hot sand, stove rooms, or artificial bagnios, and certain natural hot steams of the earth, received under a proper arch, or hot-house, as we learn from Celsus. They had also another kind of bath by insolation, where the body was exposed to the sun for some time, in order to draw forth the superfluous moisture from the inward parts; and to this day it is a practice in some nations to cover the body over with horse-dung, especially in chronic diseases, to digest and breathe out the humour that causes the distemper. In New England, they make a kind of stoves of turf, wherein the sick are shut up to bathe or sweat. Phil. Trans. N^o 384. p. 130. The same name is sometimes also given to another kind of baths, made of kindled coals, or burning spirit of wine; the patient being placed in a convenient close chair for the reception of the fume, which rises and provokes sweat in a plentiful manner: care is here taken to keep the head out, and to secure respiration.

This bath has been found very effectual in removing obstinate pains in the limbs, and venereal complaints; and, it is said, will often complete a cure, left unperformed by salivation.

BATHS, Metalline, those made of water impregnated with the *scoria* of metals. The most common and useful of this kind are those prepared with the *scoria* of iron, which abound with the earthy, saline, and sulphureous substance of the metal; and these are of excellent service for strengthening and bracing up the part to which they are applied, and recovering weak and decayed limbs; stopping various kinds of bleeding; and restoring the menstrual and hæmorrhoidal flux, where obstructed; inasmuch that they may well be substituted for the natural iron baths.

Adjacent to the smelting huts where metals are run from their ore, are to be found large quantities of the slag of copper, antimony, and cobalt, which abounding with sulphur, vitriolic salt, and an earthy principle, make serviceable baths for strengthening the lost tone of the fibres, and relaxing them when they are too stiff. These baths have likewise a detensive and cleansing virtue; so that, with prudence and due regard to circumstances, they may be used on many occasions. The way of making these artificial baths is, either to take the slags as they come hot from the furnace,

rice, or else to heat them afresh, and throw them into hot water: which is afterwards to be used, either in the way of bath or fomentation occasionally. There are other artificial baths, prepared of alum and quicklime by boiling them together in fine rain-water. Such baths are highly serviceable in paralytic disorders and weakness of the limbs.

The *pepper bath*, or *pepper wasser* on the Alps, is one of the most celebrated in Europe, and has been the subject of particular treatises, besides what has been said of it occasionally by Scheuchzer and others. It was first discovered in the year 1240, and is of the periodical kind. The water breaks forth in a dreadful place, scarce accessible to the sunbeams, or indeed to men, unless of the greatest boldness, and such as are not in the least subject to dizziness. These baths have this singularity above all others, that they commonly break forth in May, and that with a sort of impetuosity, bringing with them beech leaves, crabs, or other woodfruit; and that their course desists in September or October.

Scheuchzer professes himself of opinion, that these waters are not impregnated with any minerals; or, if they do contain any, that their virtues in curing distempers and preserving health, do not proceed from them. They are exceedingly clear, destitute of colour, taste, or smell. Phil. Trans. N^o 316. p. 151.

BATH, BALNEUM, in Chemistry. In many chemical processes it is of the utmost importance both for the security of the vessels, and the success of the operation, that the application of the necessary heat should be gradual and regulated. This is particularly the case in most distillations, and in digestions at a moderate temperature, and wherever glass vessels are employed. Hence the contrivance of baths or intermedes between the burning fuel and the vessel containing the subject of the process, in which the vessels are immersed, and whereby they receive the heat in a regular gradual manner. As fluids heat with more uniformity than solids, they are preferable where only a heat a little inferior to the boiling point of the fluid is required; and they possess this important advantage, that the heat is so kept down by evaporation, that it can never rise beyond the known and given point of boiling. But where as much even as a low red heat is required, no fluid can be employed with any convenience, and recourse must be had to some incombustible solid reduced to powder. A great variety of baths were invented by the elder chemists, especially those who were engaged in alchemical pursuits, which were supposed to require long digestions in a very accurately regulated heat; but most of these are now laid aside, and only the following kinds of baths are retained.

The *Water Bath, Balneum Aqua*, is of great use in the distillation of essential oils, of the aromatic part of vegetables, of the finer kinds of ardent spirits, in evaporating into dryness the solutions of vegetables employed in medicine whose virtue would be lost by any excess of heat, and in many other processes. The apparatus for this bath forms part of the improved ALFEMIC (which see, in *Plate III. fig. 13. A. of Chemistry*); but any vessel full of water, capable of being heated to boiling, and of containing a retort or other vessel, may be used as a water bath. As the utmost heat which any substance immersed in a boiling liquid can acquire thereby, falls short by a few degrees of the temperature of the liquid itself, the heat of a water bath cannot amount to 212°. This is considerably increased, however, by using a strong solution of sea-salt, or any other salt, instead of water; as the boiling point of saturated brine is much higher than that of mere water. This forms the ancient *Balneum Maris, Bath of Mary (the Virgin, as some*

have interpreted the term); but others with more plausibility write *Balneum Maris, sea-water, or brine-bath*.

Mercury, the fusible alloy of bismuth tin and lead, tin alone, and other metals, have been proposed for the purpose of baths, and now and then used, when a higher heat than the salt-water bath was required; but the metals are cumbersome by their weight, expensive, mercury dangerous to the by-stander from its evaporation, and they all have the inconvenience of requiring more pressure to be used than the mere weight of the substance which they are to heat, to enable it to be immersed in the melted metal.

Balneum Siccum. This whimsical term has been applied to the *vapour bath*, in which the vessel to be heated is enclosed in a kind of case filled only with the steam of boiling water. It is almost if not quite out of use for chemical purposes, but it forms a valuable implement for the kitchen.

Balneum Arenæ, Sand-bath, of all kinds of chemical baths that which is used the most extensively. In experimental furnaces, or smaller chemical operations, the vessel to contain the sand is of cast iron, very much in the form of an inverted round hat, of which the hollow part is supported by the projecting rim upon the sides of the furnace, and hangs down over the burning fuel, the flame of which plays round it and gradually heats the sand which it contains, together with every vessel buried therein. The sand should be of middling fineness, the finest as well as the very coarsest being separated by sifting; for by this means the heat is more gradually distributed. Those distillations, which at any part of the process require as much as a low red heat, are usually performed in sand baths, even in manufactures in the great way, as of aqua fortis. Sand, when thoroughly heated, continues hot for a very considerable length of time.

Bath is also used in another sense, to signify the fusion of metallic matters in certain operations: thus, in refining or cupelling, the metals are said to be *in bath* when they are melted.

BATHS, the name proper to such public or private edifices as are used for bathing.

The practice of bathing is found among all the nations of antiquity. The people of the East were ever accustomed to it, and have continued the habit to the present time; their methods being perfectly conformable to those of the Greeks and Romans. If we may credit Homer, Moschus, and Theocritus, the first ages of Greece knew no other baths than the rivers; and it was in them that the princesses Nausicaa, Europa, and Helen bathed. Homer (say the French Encyclopedists) indicates, that in his time private baths of a regular form were in use. Telemachus and Pisistratus, they observe, were conducted to baths of uncommon neatness: the most beautiful slaves in the palace bathed them, perfumed them, and adorned them with the handsomest garments. But all this is an assumption which the text of their author by no means warrants. The passage alluded to is in the *Odyssey*, book xv. l. 135.

Χερμβα δ' αμφιπολός προχίλ' ἐπεχυσσε φερούσα
Καλή χερυσίνη, υπερ ἀργυρίου λεβητος;
Νιφασσάει.

And the lines which follow plainly show, it was nothing more than a common ablution previous to an entertainment. The *Λεβητος* was a kind of vase occasionally placed upon a tripod.

The Romans, who for a long time bathed in the Tyber, borrowed the idea of artificial baths from the Greeks; their various habits of life and dress rendered such accommodations necessary; and, to make short of our relation, all the most splendid and fascinating luxuries of the emperors were

multiplied and brought together in the vast buildings of the *thermæ*.

The *thermæ*, those prodigious monuments of Roman magnificence, were formed in imitation of the Greek gymnasia. In both were assembled all the institutions favourable to health, all the exercises of the body, all that could give relaxation to the mind, or afford amusement to the people. Although the name of *thermæ*, given by the Romans to these edifices, signifies a place destined to the use of warm-baths, yet the diversity of uses to which they were applied will not suffer us to comprise the whole in a single article. All that concerns the immediate use of the baths will be found here; but for other details, we shall refer to *THERMÆ*.

The most complete and beautiful baths were composed of six principal apartments.

The first was called the *apodyterium*, where the frequenters of the bath undressed; it was furnished with tables to receive the garments of the bathers, and guards named *cap-sarii* to take care of them. This room was also called by the Romans the *spoliatorium*. All the baths were not furnished with an apodyterium. Lucian says, that in those which were without it, the *frigidarium* was used for the same purpose. The apodyterium is found neither in the gymnasium of Vitruvius, nor in the palaestra described by Lucian. It is very probable, there was no such apartment in the Greek gymnasia, and that the frigidarium supplied its place. Pliny is the only author who mentions it, when describing the baths of his country-house.

The second apartment was the cold-bath; named *Λουτρον* by the Greeks, and *frigidarium* by the Romans. This room was usually exposed to the north, and served, as we have just related, the purpose of an apodyterium to such baths as were without one; of course it was then the first apartment. The marquis Galiani imagined that the frigidarium and tepidarium were the same; but ancient paintings prove the contrary.

The third room was the *tepidarium*. Its principal use was, by the temperate air it contained, to prevent any bad effects that might be occasioned by passing too suddenly from the warm to the cold apartment. In the paintings of the baths of Titus, this apartment is found between the frigidarium and the *concamerata sudatio*. The tepidarium, according to historians, joined the frigidarium to the warm bath; and it is for that reason that Pliny calls it *cella media*, the middle room. Galen gives it the same name, and imagines it acquired this appellation not only on account of its situation in the centre, but from its temperature; for, says he, this chamber was as many degrees colder than the third or warm bath as it was warmer than the first or frigidarium. The frigidarium and tepidarium, however, were more frequented for the benefit of their air than of their water.

The fourth chamber was that which contained the stove; and was called *laconicum*, from the name of the oven which warmed it. According to Galen, it inclosed a dry heat; and he advises persons of a warm temperature not to enter it, but rather to use the warm bath, where the water absorbed by the pores would hinder the heat from being attended by any bad consequences. The laconicum also had its name, as having been originally derived from Laconia. Martial says to one of his friends (lib. 6. ep. 42.):

Ritus si tibi placeant tibi laconicum,

Contentus potes arido vapore

Cruda virgine Martiâque mergi.

Dion informs us, that they who perspired in the laconicum anointed themselves with oil, and then entered the cold bath; nevertheless in its origin the laconicum was only used by old

men and valetudinarians. This room, agreeably to Vitruvius, as well as to the ancient paintings of the baths of Titus, joined the tepidarium, and communicated to it a more temperate heat. A sort of furnace was usually suspended at one corner of the room, of a circular form, terminating in a small cupola, open at the top; which, as Vitruvius says, served to regulate the degree of heat which the bathers wished to give the room. It seems beyond a doubt that the *laconicum* itself was nothing more than a kind of furnace; and the mistakes it has occasioned owe their rise to the room in which it was placed having taken its name from it. In the paintings of Titus's baths, it is called the *concamerata sudatio*; but Vitruvius furnishes us with a proper distinction, when he says (l. 5. c. 10.), "laconicum sudationesque sunt conjungendæ tepidario;" and explains himself more fully in the next chapter, where he reckons the stove as a chamber of the palaestra. There should in one of its corners, he says, be placed the laconicum, and in another the warm bath. "Concamerata sudatio longitudine duplex quam latitudine quæ habeat in versis ex unâ parte laconicum ex adverso laconici caldam lavationem." It should perhaps have been before observed, that according to Vitruvius, the laconicum had niches which were called *sudationes*, where those who used the dry baths seated themselves, as we see in ancient paintings.

The fifth apartment was the balneum, or warm bath, called *thermolousia*, and was the most resorted to. Its size was proportioned to the number of those who bathed in it at once. Its breadth was a third less than its height, without including the gallery, called *schola*; which was carried round it, and terminated near the basin with a little wall for the bathers to lean against. This gallery was sufficiently large to contain those who waited for their turns to bathe. The middle of the room was occupied by a basin called *psicina*, or by a bathing place which had the name of *alveum*, as we see in the balneum of ancient paintings. The bath was placed immediately below the only window by which the light was admitted, that it might not be darkened by the shadows of those who were walking in the gallery.

The sixth room was the *desteresium*, or *unctuarium*. Here were preserved the oils and perfumes used both in entering and quitting the bath; and it was so constructed as to receive a considerable degree of warmth from the hypocaust.

The hypocaust was a sort of subterranean furnace, which Vitruvius calls *suspensura*; the bottom forming an inclined plane, by a gradual descent from the opening where the wood for heating it was thrown in; by which means the heat was increased, and the apartments warmed more expeditiously. It extended under the greater part of the rooms we have mentioned.

Beside these rooms particularly destined to the use of the bath, there were several others intended for the exercises previously taken. Such were the *sphaisterium*, the *consisterium*, the *coryca*, the *stadium*, the *ephebeum*, and others; all forming part of the gymnasia; but which were not always appendages of the baths, particularly those of private persons. Private baths, however, differed greatly in construction from those we have mentioned. Each possessor followed his own caprice, either in changing the rooms of which they were composed, or making the same chamber serve for different purposes. The description the younger Pliny has left us of his bath at Laurentinum, is a proof of this. In this building there was neither apodyterium nor tepidarium; and the arrangement of its other parts was very different from that of the public baths. You first entered a spacious frigidarium; where contiguous to the walls, and opposite

to each other, were placed two baths sufficiently extensive to swim in. Nigh this chamber was the unctuarium: you then entered the hypocaust, the propnigeum, and two other apartments, neat but not magnificent: you afterwards came to an hot bath, from which the sea was discovered; and farther on was the *spheristerium*, exposed to the afternoon sun. In his house in Tuscany, on entering the bath, we first find a great apodyterium, a spacious and agreeable chamber for undressing. This conducted to the frigidarium; which was darkened, and contained a bath of an appropriate size. When it was not found sufficiently spacious, there was in the open air a vast basin, which might be used for the same purpose. Not far from the frigidarium was a chamber exposed to the sun sufficiently warm, but less so than the stove; this was the tepidarium. This room had three partitions, each having a different degree of heat. The two first were entirely exposed to the sun; and though the last had not all the heat of the former, it was equally light. Above the apodyterium was the *spheristerium*, or place of exercise for different games. Although Pliny does not inform us how the bathers employed themselves after having undressed and anointed, it is highly probable they went up to the *spheristerium* and exercised, descended by another staircase into the stove, and afterwards returned to the apodyterium; not forgetting in their way to visit the tepidarium and frigidarium.

The following description, according to the Hippias of Lucian, gives another idea of the baths of the ancients, with the various apartments they contained.

“Having passed the great vestibule, to which was an easy ascent, you entered a spacious hall for the use of the domestics who attended their masters. On the left were the chambers, where they who quitted the bath retired; which were the handsomest and most agreeable of all. Farther on was another hall destined for persons of consideration. After this apartment, on each side were galleries, where the bathers changed their dresses. The centre, which was both elevated and well-lighted, contained three baths of cold water, ornamented with Laconian marble; and had likewise two statues of the same material, the one of Hygeia, and the other of Esculapius. On leaving this part of the baths by a long vaulted passage, the building became insensibly warmer, although the heat was far from disagreeable: this passage led to a light apartment where the oils and essences were preserved, which on the right hand had a communication with the *palestra*; and the door-posts of which were covered with Phrygian marble. The apartment contiguous to this, as Lucian informs us, was more beautiful in its decorations than any we have mentioned; its very floor was composed of the marble already spoken of. It was of a size sufficiently large for the bathers to walk in, and was furnished with seats. After this apartment you entered a sort of gallery, heated; of sufficient length to admit the exercises of the course. It was incrusted with Numidian marble; and led to a handsome well-lighted apartment, painted with purple, where were three warm baths. To leave it, it was not necessary you should go back by the way you entered, but across a warm chamber where the heat gradually diminished. All the chambers were lighted from the top; and Hippias shewed great judgment, in constructing the apartments which contained the cold bath so as to face the north. In regard to those which required a greater degree of heat, he exposed them to the south, the south-east, and west.”

It appears from this description, that the bath of Hippias had no apodyterium; there were only at each end of the frigidarium, which contained the three baths of cold water, tables on which the dresses were placed. The bathers

entered a warm passage which conducted to the unctuarium; whence having anointed themselves they gained the *spheristerium*, the largest and handsomest apartment of the whole. When the exercises were finished, they passed into the hot bath by a gallery where there was sufficient heat to preserve the perspiration first excited in the *spheristerium*; so that when the bathers first entered the warm bath, the difference they found was scarcely perceptible; since the warmth of the water was pretty nearly the same with that of the body. After having used the bath, they returned by a shorter way, and crossed an apartment where the heat diminished in proportion as they approached the frigidarium where their dresses had been left.

The following is the description which Vitruvius has left us of the *Grecian* baths. Having described the different apartments of the gymnasium, he says: “On the right of the ephebeum is built the *corvceum*, or the room for shaving, dressing, &c.: near which should be the *considerium*, where the sand for the wrestlers is preserved; and at the corner of the *perystyleum*, the *loutron*, or cold bath. On the left of the ephebeum, the *eleothesium*, or apartment for the essences and oils: near which is constructed the frigidarium; whence a passage should conduct the bathers to the propnigeum near the stove in the corner of the portico. Adjoining, on one side the frigidarium, is built the vaulted chamber for perspiration, which is always made twice as long as wide; and at one of its angles, usually that opposite the warm bath, the *laconicum*.”

The disposition of each of the apartments we have mentioned varied still more in the *thermæ* of the Romans, although their plans evince uniformity to a certain extent. As the Romans had two *perystilia* in their *thermæ*, it seems right to conclude they had a double order of baths. Varro proves incontrovertibly, that the women bathed in different apartments from the men; for, in speaking of the public baths of Rome, he says: “Item primum balneum nomen et Græcum introit in urbem: ubi bina essent conjuncta ædificia lavandi causâ; unum ubi viri, alterum ubi mulieres lavarentur.” What Martial and St. Cyprian relate of the baths, where the men and women bathed indiscriminately, does not confute this passage; since writers attribute those indecencies to none but women of infamous character:

“Cum te licentâ balnearior extinctâ
Admittat inter builtuaras mœchas.”

This separation is conspicuous in the baths of Caracalla; a great part of which was surrounded by a vestibule which encompassed the principal buildings of the *thermæ*. This part was divided into fifty vaulted halls separated from, but perfectly resembling each other. One of these yet remains entire, and sufficiently indicates how the others were disposed. It is approached by a small vestibule. The room in which the bath was placed, was thirty-one feet in length by fifteen feet three inches wide: the basin was of masonry, with a border of larger stones extending eighteen inches from the edge of the hollow. The cavity between the sides was twelve feet wide by fifteen long. It was defended to in front by seven or eight steps extending the width of the bath: four above the brink, and three or four went to the bottom of the basin: and the whole was lighted by a small opening at the top. A thousand persons could bathe in this part of the *thermæ* at once.

When the water flowed into these baths, it seems to have been only lukewarm, as it was brought from the hot baths of the great *thermæ*; of which these, as we have already mentioned, formed only the outer circle. The water was conveyed from these baths, by pipes, into a great piscina,

or pool, destined for the use of those who wished to exercise themselves in swimming.

In front, on the right and left, were other baths for people of superior consequence. In the room of basins they had large bathing vessels, which were of copper, porphyry, granite, or basalt. They also contained seats of marble or porphyry; of which we yet see a great number at Rome. Olympiodorus assures us, that the baths of Caracalla had no less than sixteen hundred.

The grand hall was a rotunda, 111 feet diameter; which is believed to have been called *cella solaris*, or the hall of sandals, of which Spartianus speaks in these terms: "Cellam solarium archæcti negant posse ulla imitatione quâ facta est fieri." It seems to have had its name from the bars of copper and bronze which, according to some, formed its pavement, and to others its ceiling; bearing some resemblance to the fastening of the sandals among the ancient Romans. It had also large plates of bronze or copper, which covered and ornamented the piers of the windows and other parts of the rotunda. It contained a number of vessels in which the warm bath was taken.

Of all that relates to the baths, nothing has so embarrassed the learned as the manner in which hot water was supplied to all the receptacles for bathing which have been found. For if we suppose, and it may be done without exaggeration, that each bath in the thermæ of Dioclesian was capable of containing six bathers, 1800 persons might have bathed at once. But as no vestige remains, sufficient to favour our conjectures as to the manner in which the water passed into these vessels, we must content ourselves with what Vitruvius has said upon it.—Baccius has treated this subject better than any of the moderns. He imagines the water was conveyed from reservoirs outside the thermæ, and that machines were used for raising it to that height, which, agreeably to his examination of Dioclesian's baths, seemed requisite. He was also induced to conclude, that the water was heated outside the thermæ, from the number of pipes which he saw underneath the area of the building; where there had never been any alteration, and which were all surrounded by other pipes from the hypocaust. But this supposition appeared to Baccius himself so replete with difficulties, that he pushed his researches on this matter no farther.

The two figures of the water towers or reservoirs for the baths of Caracalla, engraved by Piranesi, will suffice to explain how easily the Romans heated the largest body of water their thermæ could contain.

The water tower of Caracalla received its supply from the aqueduct of Antoninus, part of which passed by the Appian way.

It appears from the plan of this reservoir, that it had, immediately above the hypocaust, twenty-eight vaulted chambers; that these chambers formed two ranges of fourteen each; and that they had a communication one with the other. Above these were twenty-eight other chambers, which were connected with each other in like manner, though only one of them communicated with the chambers below. Above all these was a spacious reservoir, not very deep, but which extended the whole length of the water tower; in this, the water received considerable warmth from the heat of the sun, before it passed into the chambers. This reservoir did not receive its water directly from the aqueduct, but from an intermediate cistern. Whenever it appeared necessary to draw off the water of the lower chambers to fill the bathing places, the water of the reservoir became useless, and would have overflowed but for an opening on one side of the cistern, by which it escaped with-

out going into the baths. During all this time the water of the reservoirs was tranquil. The cistern answered two purposes; it prevented any agitation in the water of the reservoir, and carried off that which was of no use. When the twenty-eight vaulted chambers, immediately above the hypocaust, began to heat, the warmth they acquired was quickly augmented; as there was only one of them which communicated with the exterior air.

The strength of the walls and vault was quite sufficient to resist the rarefaction of air within the water, and of consequence to hinder its evaporation from producing danger. It was necessary that it should have pipes to give the water a sufficient heat for the usage of the bath. When the hour of bathing came, the warm water was let into the bathing places from the lower chambers; where it ran with incredible swiftness, and rose to a perpendicular height equal to the surface of the reservoir of the water tower.

To hinder the water from cooling as it passed through the subterranean pipes, they were inclosed in others which came from the entrance of the hypocaust, forming a sort of double tunnel, and acquiring a considerable degree of heat before the water entered them.

Each chamber was within the walls 49 feet long, 27 wide, and about 30 high. The number of square feet on the surface of the lower chamber amounted to 38,500. If we allow for the medium height 30 feet, the quantity of water contained in the lower chambers amounted to 1,143,450 cubic feet.

The ancients do not inform us how they discovered the method of heating such large volumes of water. We are therefore in the dark whether it was an invention of the Romans, or whether they brought it with them from the East. It is reasonable, however, to suppose, that such methods could be of no use before the construction of the thermæ at Rome, and of course could not be older than the time of Augustus; in whose reign, Dion Cassius informs us, Mæcenus built a warm bath capable of admitting persons to swim in.

This method, or one very similar, was used in all the baths of Rome. That described by Vitruvius was insufficient to furnish water for these vast buildings, which Ammianus Marcellinus compares to provinces (*lavacra in modum provinciarum extructa*); though it was undoubtedly the case in private baths. They heated the water of the bath, says Vitruvius, by means of three vessels of copper, so disposed that the water flowed from one to the other. One was called *caldarium*, another *tepidarium*, and the third *frigidarium*. The marquis Galiani observes, that it is no easy matter to give a precise idea of the situation of these vases above the furnace. Cæsarino and Caporali have engraved one above the other, or rather one within the other, placing the *frigidarium* above the *tepidarium*, and that above the *caldarium*, which was placed immediately above the furnace. But the great difficulty is, that in this arrangement the heat, by the ascension of the flame, ought to warm the upper vase, or *frigidarium*. Perrault, on the contrary, places the three vases on a level; and he imagines that syphons carried the water of one vase into another: but how, without a piston, or some such expedient, the water could be raised so as to descend, he has not explained.

The ancient paintings of Titus's baths place these vases upon three steps, in such a manner that the bottom of the water of one vessel shall be upon a level with the aperture of the other; so that it is easy to comprehend how the water was conveyed. But the marquis Galiani believes, that this disposition is not altogether agreeable to the truth; and that it was adopted by the painter, only to afford a more clear idea how the water was transferred.

I believe,

I believe, he says, that the three vases were upon a kind of level: the caldarium immediately above the furnace; the tepidarium a little backward, so as to receive a reverberation of the heat more than the fire itself; and the frigidarium upon a massy pedestal, so that the warmth could not reach it. From the caldarium to the baths was a pipe, which, by means of a cock, supplied any quantity of water that was requisite. Another pipe carried the water of the reservoir to the frigidarium, and kept it at the same level. All the figures which Vitruvius has given of this process, seem to require that an attendant should overlook this transfusion of the water: but that author himself tells us, that the operation was performed without assistance; *ita collocanda uti ex tepidario in caldarium quantum aque caldæ exiit influat de frigidario in tepidarium ad eundem modum.*

They had also other means of heating the water of the baths. We construct, says Seneca, a species of vases high and narrow, in the form of dragons and other fanciful shapes, in which we place pipes of native copper, of a spiral form, through which the water passes till it acquires a sufficient degree of heat. In the same degree as the cold water enters the pipes, the warm passes out; so that all the water which runs through, acquires the same temperature. Seneca explains the advantage of this process, and informs us the tube through which the water passes having no communication with the fire, the vapours are not mixed with smoke; *ne trahit vaporem evaporatio, quia clausa pertrahitur.*

The parallel which Seneca has given in his letters between the baths of Scipio Africanus and those of his own time, is highly interesting, and will probably elucidate much that has been already written on the subject.

“Scipio’s bath,” he says, “was small and somewhat dark, agreeable to the ancient custom; for our ancestors thought that a bath could not be warm enough unless it was close. It was therefore a great pleasure to me to compare the manners of Scipio with our own. In this little nook did Scipio (the dread of Carthage, and to whom Rome was indebted for having once taken it) use to bathe his body when fatigued with rustic labours. Under this low and fordid roof he stood, and disdained not to tread so vile and mean a floor. But who is there in our time who would condescend to bathe in this way? A man thinks himself poor and mean, unless the walls are decorated with large and precious embossments; unless Alexandrian marble is pointed and inlaid with Numidian rough cast; unless a rich and curiously variegated plaitering be spread upon them in picturesque; unless the roof is covered with glass-work; unless the Thasian stone, once reckoned a scarce and curious ornament, even in some temples, now compass about the pools in which we bathe our bodies when enfeebled with fatigue at some trifling sport: in short, unless the water is conveyed by a silver spout. I am speaking as yet of common stoves; but what shall I say when I come to speak of our freedmen? What noble statues! What vast pillars supporting nothing; but placed there for mere ornament, and the vain ostentation of expence! What large and far-sounding cascades! We are arrived to such a pitch of delicacy and extravagance, that we cannot tread but upon the most precious marbles.

“In Scipio’s bath there are some chinks, rather than windows, cut out of the stone wall to let in the light without hindering the strength of the building. But now we call the baths moth-houses and dungeons, if they are not so contrived as to admit the whole day’s sun through the most spacious windows, whereby men are tanned as well as washed; and from the bathing vessels have a prospect both of the meadows and the sea. So that these baths, which, at their first con-

struction, called together a vast concourse of people, and filled them with admiration, are now rejected as poor antiquated things; while luxury is daily presenting some novelty that must at last prove its own ruin. Formerly there were but few baths, and those not ornamented with any costly decorations; for to what purpose is it to adorn a common room, open to any one that paid his farthing, and which was built not for pleasure but for use? It was not customary to have the water sprinkled or poured in upon the bathers; nor did it always run fresh, as from a warm spring; nor did they think it material, how clear the water was wherein they were to wash off their filth.”

From this letter of Seneca, we perceive to what a pitch of magnificence luxury had carried the edifices destined for the baths. And nothing gives a stronger confirmation to the account, than the fragments of those buildings which have reached our own time. The greater part exhibits to us the most precious furniture. The hall of the bath, discovered a few years since at Otricoli, has preserved the reliques of the rarest marbles; its pavement was formed of the same wonderful kind of mosaic which at this day ornaments the rotunda of the Vatican museum. In the baths of Titus, the marble coating is carried to the height of about ten feet; where, to preserve the paintings from the dashing of the water, the walls were covered. It appears that in these baths one division of the rooms, especially those which were destined for the warm baths, had no openings to admit the light; at least none have been found. When it became fashionable to frequent the baths by night, it was necessary the place should be lighted by lamps and candelabres; the introduction of which contributed very much to the decoration of the apartments. The most magnificent we have seen at Rome, have been found in the *Thermæ*: their light was reflected by masses of crystal, suspended from the roof or fixed against the walls, so as to produce the most effulgent light.

The use of glass in the decoration of the baths, commenced about the time of Pliny, who calls it a modern invention; *novitium et hoc inventum.* It did not exist, as far as has been discovered, in Agrippa’s time; whose baths were covered with ornamented clay or stucco, called *albarium opus.*

Having thus brought the history of the Roman baths to a conclusion, it will not be irrelevant to add a brief notice of the principal ruins of them which remain, taken chronologically.

The better half of Paulus Æmilius’s baths is nearly perfect.

Those of Livia, on the Palatine hill, and under the ruins of the imperial palace, still shew two small apartments entire, decorated with stucco, painting, and gilding.

The magnificent ruins of the baths of Titus, Caracalla, and Dioclesian, still shew the entire plans: sufficient remains of the walls to determine the sections and elevations with tolerable certainty; and of the construction of the conduits and stoves, enough to give the most satisfactory information.

There are some remains, but very incomplete, of the baths of Constantine, in the gardens of prince Colonna.

All the rest of the ancient baths, in or about Rome, are nearly or entirely destroyed: and it is to be remarked, that the baths of Titus, Caracalla, and Dioclesian, are entirely stripped of their magnificent columns and fine marbles, excepting the great hall of Dioclesian’s baths, which was converted into a church by Michael Angelo, and its granite columns of single stones, each forty feet in height, preserved.

That the Romans, who enjoyed dominion in our island near four hundred years, had their baths, is evident from the frequent ruins of them which are found; and some instances occur where the builders had undoubtedly the thermæ of their parent country in view. At Hovingham in the north riding of Yorkshire, 1735, a Roman bath was discovered, which had its sudaria and vaporarium (Camden, ed. 1739, in. 85.); and ten years after, in taking down the abbey house at Bath, to build a new set of baths called the duke of Kingston's, the workmen found remains of very noble Roman baths and sudatories, whose springs and drains were made use of for the present baths. The plan and elevation of them were engraved by Mr. Gough. (Ibid. i. 79.)

Nor while mentioning the ancient baths in England, must we forget one instance where a magnificent building of the kind occurs among the monastic conveniences of the middle ages. Hugh, the sacrist of the monastery of Bury, we are told, early in the twelfth century finished the *aulam hospitium* and *balneatorium* of his house; and Sampson, who was elected abbot in 1182, appears to have completed the latter edifice upon a scale, for those times, peculiarly grand. (*Aquæductum et aquam per rivulos derivatam et lavatoria opere mirifico et magnitudine miranda consummavit.*) See Leland, *Itin.* vol. iv. App.

But it must be owned, that in spite of all the advantages derived from the habitual use of baths with respect to health and cleanliness, the moderns have till lately very much neglected to employ them; though from this censure we must except the Orientals and the Turks, among whom the practice of the bath has been more easily preserved, on account of its connection with religious worship. Their manner of bathing is very similar to that of the ancients; they have still vast edifices for the purpose, which are heated by means of pipes, and receive light from the top: and though the use of the strigyl (see ARCHITECTURE, *Plate III.*) may not have been preserved, proper frictions for the excitement of perspiration are still used; and the instruments adopted by the ancients are replaced by rough cloths and flannels. The rich among them have private baths, in the construction of which they are expensive, and devote to them the most considerable part of their mansions.

Among the modern Europeans, the practice of bathing, generally speaking, has returned to the same condition it was in when Homer described it in the earlier ages of Greece. It is in the river, during the heat of summer, that the multitude bathe; and that more for pleasure than on any other account: without once reflecting on the accidents which are likely to result from the crudity of the water, the intemperature of the air, or the action of the sun, to which they are frequently exposed.

At Florence, on the bank of the Arno, public baths were constructed by the late duke, with such accommodations as seemed most appropriate for general use: adjoining which there are other baths belonging to private persons; and gardens of promenade.

What are called public baths at Paris, are far from uniting these advantages; they are no other than large boats, called *tone*, covered with a cloth, with small ladders attached by cords, to facilitate the purposes of bathing. The French have also private baths for hire, similar to those in England; and many of their larger mansions are furnished either with domestic baths of the larger kind, or bathing vessels formed of metal.

Those which are called natural baths, are usually buildings constructed nigh the sources of mineral waters; such as the baths of Puzzuoli, Baix, and St. Germano, near Naples:

Pisa, in Tuscany; Bourbon and Vichi, in France; Buxton, Bath, and Harrowgate, in England.

Of the engravings which accompany this article, *Plate I.* exhibits the plan of the baths of Caracalla; of the references in which we give the following explanation.

1. The great square, surrounded by a portico, for the exercises of the stadium.
 2. Those parts of the porticos which served for entrance to the vestibules of the palæstra.
 3. The *cella solæaris* of the palæstra: the gates of which were furnished with lattice work of bronze.
 4. Vestibules of the great hall.
 5. The great hall, furnished with the *xystum*.
 6. Other vestibules belonging to the lateral apartments of the palæstra.
 7. Others, narrower than those already mentioned, leading to the same apartments.
 8. Halls, open at the top, whose sides were ornamented with basso-relievos in marble. A fragment of one of the last of these was lately in the possession of cardinal Albani.
 9. Anti-rooms belonging to the *xylla*.
 10. Common entrances to the same.
 11. Openings to give the *xylla* light.
 12. A spacious *xystum* in the middle of the palæstra, for the exercises of the *athletæ*.
 13. Apartments in which the *athletæ* anointed themselves and left their vestments, with staircases ascending to the upper part of the *cella solæaris*.
 14. Receptacles for the rain-water from the roofs of the porticos (*fig. 19.*), which was conveyed by pipes to the lower baths.
 15. Other uncovered receptacles, for the same purpose, formed in the side walls.
 16. The portico, whence passing through the *xystum* you reached the great bath: it was exposed to the S.W. and was sometimes warmed by the sun, and at other times by furnaces.
 17. Chambers or baths belonging to the wrestlers, and other combatants, of the theatre and *xystum*.
 18. The cistern of water in the centre.
 19. Porticos, ornamented by niches, with magnificent fountains, serving as a shelter for the populace from the rain and sun.
 20. Double portico before the theatre.
 21. Seats for the spectators at the games; in front of which, upon occasion, the stage, and scenes for theatrical representation, were erected.
 22. Open spaces between the porticos and the great hall or saloon.
 23. Uncovered halls.
 24. The *athenæum*.
 25. Open space in front of the philosophic walks.
 26. The philosophic walks.
 27. Quarters for the prætorian guard.
 28. The great *exedræ*, for trials of strength.
 29. Apartments appertaining to the *exedræ*, subdivided into smaller ones for the accommodation of the officers and exercisers in the different games.
 30. Apartments for the scenes, and other theatrical apparatus.
 31. Openings with iron gratings, for the admission of light to the lower story.
 32. Staircases from the lower to the upper story.
 33. Vestibules of the upper story.
 34. Other staircases of ascent to the porticos.
- Lower Story.*
35. Quarters of the prætorian bands; with porticos in front.

36. Piscinæ, or pools of cold water.
 37. Porticos erected at a later period, by Alexander Severus.
 38. Cold bath with fountains in the centre.
 39. Walks for public accommodation.
 40. Magnificent fountains.
 41. Walls surrounding the summit of the hill on which the baths of Caracalla were erected.
 42. Open space around the reservoirs of water.
 43. The aqueduct of Antoninus, which supplied the baths.
 44. Intermediate reservoir, into which the water of the aqueduct was discharged.
 45. The opening by which the water was conducted to the warm baths.
 46. The reservoir.
 47. Walls of the city, anterior to those of Aurelian, which were enlarged by Caracalla, for the extension of the thermæ.
 48. The fountains mentioned in *fig. 38.*
 49. Porta Capena in the city wall.
 50. Porta Terentiana.
 51. The Appian way.

Plate II. exhibits a painting from the baths of Titus, on a brown ground, representing three slight temples: in the centre one a statue, supposed to be Apollo, with a priest on either side; and above each of the lateral temples a bas-relief, representing the sacrifices of Bacchus. The smaller figures in Arabesque.

Here may be remarked, that in strict contradiction to all that is asserted by the French writers, the paintings of the ancients, whether Greek or Roman, are in bad perspective.

Plate III. contains a section of the baths of Caracalla, from Piranesi; with Montfaucon's idea of explaining the relative situation of the different apartments in the Roman thermæ.

BATH, in *Jewish Antiquity*, is the name of a liquid measure, containing the tenth part of an omer.

Some distinguish five kinds of baths: viz. the greater bath, containing 80 pounds of water, or, according to Josephus, 1440 Roman ounces; the second bath, containing 100 ounces; the third, 66½ ounces; the fourth, containing 25 ounces; and the fifth, 6½ ounces of water. *Beverin. Sync. de Mens. p. ii. p. 127.*

Some have estimated the sacred bath at half as much again as the common bath; but there is no sufficient reason for this distinction. *Calmet.*

BATH, Knights of the. This order was instituted in England at the coronation of Henry IV. in 1339, and revived by George I. by his letters patent, bearing date at Westminster, the 18th of May in the 11th year of his reign, 1725, in the following words:

"George, by the grace of God, of Great Britain, France, and Ireland, king, defender of the faith, &c., to all to whom these presents shall come greeting. Whereas our royal predecessors, upon divers wise and honourable considerations, have, on occasion of certain august solemnities, conferred with great state, upon their royal issue male, the princes of the blood royal, several of their nobility, principal officers, and other persons distinguished by their birth, quality, and personal merit, that degree of knighthood which hath been denominated the knighthood of the bath; we, being moved by the same considerations, do hereby declare our royal intention not only to re-establish and support the said honour of knighthood in its former lustre and dignity, but to erect the same into a regular military order: and, accordingly, of

our especial grace, certain knowledge, and mere motion, and by virtue of our royal prerogative, being the fountain of honour, we have instituted, erected, constituted, and created, and by these our letters patent, do institute, erect, constitute, and create a military order of knighthood, to be and be called for ever hereafter by the name and title of "The Order of the Bath," whereof we, our heirs and successors, Kings of this realm, for ever shall be sovereigns; which said order shall consist of a great master, to continue during the pleasure of us, our heirs or successors, and thirty-six companions, to be from time to time nominated and appointed by us, our heirs and successors, wherein a succession shall be always regularly continued; which said order shall be governed by statutes and ordinances, to be from time to time made, ordained, altered, and abrogated, by us, our heirs and successors, at our and their pleasure. And to the end that such statutes may be legally established, we, following the example of our royal predecessor king Edward the Third, of glorious memory, founder of the most noble order of the garter, who gave sanction to the statutes of that order, by affixing to them the seal which had been by his command made and appointed for the same order, do hereby direct and appoint, that a seal shall be immediately engraven, having upon one side the representation of our royal person on horseback in armour, the shield azure, three imperial crowns or, the arms usually ascribed to the renowned king Arthur, with this circumscription, "Sigillum Honoratissimi Ordinis Militaris de Balneo;" and on the reverse, the same arms empassing our royal arms: and our royal will and pleasure is, that the said seal shall for ever hereafter be the seal of the said order of the bath; and that the statutes to be perpetually and inviolably observed within the said order, shall be established and sealed by and with the same seal: and we do hereby for us, our heirs and successors, declare and ordain, that the said statutes so to be given by us, our heirs or successors, to which the said seal shall be affixed, shall be of the same force and validity as if the same statutes, and every article of them, had been verbatim recited in these our letters patents, and had been passed under the great seal of this our realm. And further, we do hereby ordain, constitute, nominate, and appoint our right truly and right entirely beloved cousin John duke of Montagu to be the first great master of the said order, to hold the said office during our pleasure, with such powers, privileges, and emoluments, and subject to such regulations as shall be for that purpose appointed in the statutes to be established by us, our heirs or successors, as aforesaid. And whereas it is absolutely necessary, for the dignity and service of this order, that there should be officers peculiarly appropriated thereto, we do by these presents, for us, our heirs and successors, will and ordain, that there shall be for ever hereafter a dean, genealogist, king of arms, register, secretary, usher, and messenger, of and belonging to the said order, whose respective duties, privileges, emoluments, and perquisites shall be particularly expressed and declared in the said statutes; and we do hereby for us, our heirs and successors, constitute, create, and appoint the dean of the collegiate church of St. Peter's Westminster, for the time being, to be for ever hereafter dean of the said order, and do for us, our heirs and successors, give and grant full power and authority to the great master of the said order, for the time being, to constitute, nominate, and appoint, under the seal hereby appointed for the said order, a genealogist, king of arms, register, secretary, usher, and messenger of the said order; and from time to time to fill up the places of such officers upon vacancies, according to such rules and directions, as shall for that purpose be laid down and expressed in the said statutes to be given as aforesaid. And to the end that the

respective fees to be paid to the several officers of the said order of the bath by such persons as shall be nominated unto and accept the honour of a companion of the said order, may be certain and fixed, we do by these presents, for us, our heirs, and successors, will and declare that all such fees shall be especially and particularly ascertained and established in and by the statutes to be given and ordained to and for the said order, by us, our heirs or successors, under the seal hereby appointed for the said order, and shall be of the like force and effect as if the same had been particularly expressed and set forth in these our letters patents: and, lastly, we do hereby, for us, our heirs and successors, grant that these our letters patents, or the enrolment or exemplification thereof, shall be in and by all things good, firm, valid, sufficient, and effectual in the law, according to the true intent and meaning thereof; any omission, imperfection, defect, matter, cause, or thing whatsoever to the contrary thereof in anywise notwithstanding. In witness whereof we have caused these our letters to be made patents.

Witness ourself at Westminster, the eighteenth day of May, in the seventh year of our reign."

The badge, cognizance, or ensign of this order, is a rose, thistle, and shamrock, issuant from a sceptre between three imperial crowns, surmounted with the motto of the order; viz. "Tria juncta in uno;" the whole of pure gold, chased and pierced, and is worn by the knight elect, pendant from a red ribbon across the right shoulder. The collar is of gold, weighing thirty ounces troy weight, and is composed of nine imperial crowns, and eight roses, thistles, and shamrocks, issuing from a sceptre, enamelled in their proper colours, tied or linked together with seventeen gold knots, enamelled white, having the badge of the order pendant thereto. The star consists of three imperial crowns of gold, surrounded by the motto upon a circle of red, with rays issuant from the centre silver, forming a star, and is embroidered on the left side of the upper garment. The installation dress of a knight of the bath is a furcoat of white sattin, with a mantle of crimson sattin lined with white, tied at the neck with a cordon of silk crimson and gold with gold tassels, and on the left shoulder is embroidered the star of the order; a white silk hat, adorned with a standing plume of white duck feathers, white leather boots, edged and heeled, crimson and gold spurs, a sword in a white leather scabbard, with cross hilts gold. The knights receive the order by investiture in the king's closet, or, if abroad, by warrant. The ceremony of investiture is as follows. The dean, the knights, and the officers of the order attend in the privy-chamber in their mantles and collars, and proceed from thence, after the levee, into the sovereign's presence, making the usual reverence, in the following order; gentleman usher of the order in his mantle, chain, and badge, bearing the scarlet rod; regiller and secretary of the order in their mantles, chains, and badges; bath king of arms in his mantle, chain, and badge, bearing the sceptre of bath, carrying the ribbon and badge of the order on a crimson velvet cushion; the genealogist in his mantle, chain, and badge; the knights of the order with their mantles, collars, and badges; the dean of the order in his mantle, chain, and badge; the first knight and principal companion, acting as great master. Then by his majesty's command the intended knight is introduced between the two junior knights of the order, preceded by the gentleman usher of the order, with reverences as before. The sword of state is then delivered to the sovereign by the second knight of the order in seniority, and the intended knight is knighted therewith. Then the principal knight companion presents the ribbon and badge to the sovereign, and his majesty puts it over the new

knight's right shoulder, who, being thus invested, has the honour to kiss the king's hand. The procession then returns to the privy-chamber in the order above mentioned. After the investiture, the knight wears only the ribbon and badge; as he cannot wear either the collar or star before his being installed, without a letter of dispensation, which is only granted to those on foreign service. On the revival of the order, king George the First allowed the chapel of king Henry the Seventh in Westminster abbey to be the chapel of the order, and ordained that each knight's banner, which shall be placed over his stall, shall be two yards in length, and one yard three quarters in breadth, fringed about with red and white silk; and that, in the lower margin, the name and title of the knight shall be inscribed with letters of gold upon a black ground; and that the crest, helmet, and sword shall likewise be affixed to the stall, together with an escutcheon of his arms and supporters, enamelled within a circle gules, having thereon the motto of the order in letters of gold, and his name and title in like manner as the knights of the garter are in St. George's chapel, Windsor; the arms also of his three esquires are enamelled on one plate, with their names and title affixed thereto, and placed under the knight. At an installation of the order, each knight is allowed three esquires, who must be by the statutes "gentlemen of blood, bearing coat armour;" they precede their knight in the procession, having for their dress a crimson silk waistcoat with sleeves, breeches, stockings, and shoes with roses, the whole of which are silk, of the same colour, with a furcoat of white silk, lined and edged with crimson, having a hood of the same affixed thereto, and on the right shoulder of the furcoat the plain escutcheon of the order, "azure, three imperial crowns or;" a black silk hat or coif: for which service each esquire "shall, during the term of his life, enjoy all rights, liberties, privileges, exemptions, and advantages which the esquires of the sovereign's body, or the gentlemen of the privy-chamber do lawfully enjoy, or are entitled unto by virtue of any grant, prescription, or custom whatsoever; and the eldest son of every of these esquires shall have and use the addition and title of esquire in all acts, proceedings, and pleadings: provided that all these esquires to be entitled to these privileges, shall have certificates of their qualifications before their respective admission, and likewise an exemplification of their actual performing their duties upon the creation of any knight or knights of the bath, attested by the great master under the seal of the order." An esquire of the order is allowed to hunt and fish in the king's royalty, and is exempt not only from serving the office of high sheriff, but any parochial office. To prevent any abuses in the claiming these privileges and exemptions, the following notification was inserted in the gazette, previous to the installation of the order in 1803, when twenty-two knights were installed, attended by their esquires, sixty-six in number.

"It is hereby notified, that no exemplification will be issued to any esquire, from his royal highness the duke of York, after the ensuing installation, until it shall be certified to his royal highness by the genealogist, that the pedigree and coat armour of the several knights and their respective esquires have been entered in the genealogical books of the order, in obedience to the said statutes.

Given at the Horse-guards, this 13th day of May 1803; Frederick, acting as great master of the said most honourable military order of the bath."

The dress of the officers of the order is as follows: viz. the mantle and cordon of the dean are the same as the knights; he wears a gold chain, with the badge of the order, but no collar. The genealogist, king of arms, registrar, secretary, and usher's is a white sattin mantle or robe lined with crimson, having

having on the right shoulder the badge of the order tied about the neck with a cordon, the same as the knight's; under it is a furcoat like the esquire's, with a gold chain about their necks, to which is pendant an escutcheon of gold, thereon enamelled the badge of the order; except that on collar days, the badge is worn pendant to a red ribbon. The office of genealogist is a distinct office of record for the pedigrees and coat armour of the knights of the order and their esquires, which are entered in a regular series from the year 1399 to the present time. The office of genealogist has, from the revival, been successively filled by John Aulstis Esq., John Suffield Brown Esq., and George Naylor Esq., York herald, its present possessor.

The order of the bath doth not appear to have been of greater antiquity, in this kingdom, than the reign of Henry IV. who, on the day of his coronation, conferred that dignity upon forty-six esquires, who had watched all night before, and had *bathed* themselves; yet this degree of knighthood may justly boast of a much earlier antiquity. The learned William Camden, and Jean Du Tillet suppose it to have been practised by the old Franks, or inhabitants of lower Germany: with whom Mr. Aulstis (who was genealogist of the order on its revival) is of opinion, the Saxons, who invaded England, had the same common descent; and who, upon their settlement in England, introduced the same method of knighthood. Du Tillet further remarks, that those ancient Franks, when they conferred knighthood, observed many solemn rites. Before they performed vigils, they bathed, to signify that such as were admitted to this degree should be of a pure mind and honest intentions; be willing to conflict with any dangers or difficulties in the cause of virtue; take care, both in their words and actions, to follow the maxims of prudence; and, on all occasions, religiously observe the motto of the order, "Tria juncta in uno;" which implied a true belief of the Trinity: which rites and conditions, according to his testimony, still continued to be practised in England; and from the practice of these, gentlemen were denominated knights of the bath. Mr. Aulstis, with his usual precision and clearness, hath fully proved that William the Conqueror, and the succeeding kings of England, conferred this degree of knighthood as well in Normandy as in England. We have a very particular detail of the ceremonies that were used in creating knights of the bath, at the coronation of king Henry V.: and our historians and records amply vouch that from that time, till the reign of king Charles II. inclusive, it was the usual practice to create knights of the bath at, or previous to, the coronation of our kings, the creation of princes of Wales, and at the celebration of their nuptials, and those of others of the royal family. King Charles II., previous to his coronation, created no less than sixty-eight knights of the bath; from which time no knights of that degree were created, until the revival by George I. in 1725.

BATH Metal is a preparation of copper with zinc, which gives a more beautiful colour than the calamine used in the preparation of the common brass.

BATH Kol, in *Jewish Antiquity*, a species of revelation by a voice or echo from heaven.

The word signifies, in the Hebrew original, *daughter voice*, or *daughter of a voice*; for it may be interpreted both ways. It seems to have been thus called with respect to the oracular voice delivered from the mercy-seat, when God was consulted by urim and thummim: this latter was the grand and primary voice of revelation; the former, of secondary dignity, and inferior to it as the daughter to the mother.

The Jewish writers speak of three kinds of revelation

among them: the first by urim and thummim, which obtained from the erecting of the tabernacle to the building of the temple; the second by the spirit of prophecy, which prevailed from the beginning of the world to the death of Malachi; the third, the *lath kol*, or *filia vocis*, which took place when the spirit of prophecy wholly ceased in Israel; and was, says Grotius, the sole oracle which remained during the time of the second temple.

This bath kol, says Dr. Prideaux, was no such voice from heaven, as the Jewish, and particularly the Taimudical, writers pretend; but only a fantastical mode of divination of their own invention, resembling the "Sortes Virgilianæ" among the heathens. (See SORTES.) Prid. Conn. pt. 2. b. 5. vol. 3. p. 463. Godw. Moses and Aaron, lib. 4. c. 8. Lightfoot's Works, tom. i. p. 485. Grot. in John, xii. 28.

Danzius has a dissertation on the iniquity and imposition of the bath kol: "De filia vocis nefanda, divinæ æmula."

BATHA, in *Ancient Geography*, the ruins of an ancient city of Africa, in the kingdom of Algiers, about 2 leagues south of Oran, which was destroyed in the wars that raged between the African powers, about the beginning of the seventh century. It has been remarkable, in more modern times, for a little chapel, erected in memory of a marabout, who lived among these ruins, and by the presents he received for his hospitality to travellers, became rich enough to maintain 500 disciples, whose employment it was to go through a long litany of all the divine attributes, by the help of their beads, at certain hours of the day: but the sect has of late declined and is almost extinct.

BATHA, a town of Ethiopia, near Egypt. Pliny.

BATHA, *Bach*, or *Bachia*, in *Geography*, a town of Hungary, situate near the Danube, and capital of a county of the same name. It was formerly the see of a bishop, now united to Coloeza; 20 leagues south of Buda. N. lat. 46° 40'. E. long. 20° 40'.

BATHA, a town of Ethiopia, on the confines of the country called by the Arabs Berbera, and more commonly Zanguebar.

BATHA, a name sometimes given to the isle of Bas; which see.

BATHASECH, a town of Lower Hungary, in the county of Tolna, on the Sarwitz.

BATHENAS, in *Ancient Geography*, a town of Syria, between Cyrrhus and Edessa. Anton. Itin.

BATHGATE, or **BATHGET**, in *Geography*, a market town in the county of Linlithgow, in Scotland. There are three fairs held annually in Bathget; second Wednesday in April, first Wednesday after Whitsunday, O. S. fourth Wednesday in June, third Wednesday in July, third Wednesday in August N. S. and first Wednesday after Martinmas. The circumjacent country is rather hilly, yet by no means destitute of agricultural improvement: the soil of late is made to yield abundant crops; and rural economy advances daily. In a morass, about a quarter of a mile from Bathget, some slight traces of the principal residence of Waller, high steward of Scotland (the founder of the royal house of Stuart), are still discernible. The mansion, and lands thereto belonging, were the dowry bestowed on the high steward's wife, lady Margery, by her father king Robert the Bruce, in A. D. 1316.

BATHING, the act of using or applying a bath; that is, of immersing the body, or part of it in water, or other fluid. See BATH.

Bathing, on a religious account, is more properly called ABLUTION, or BAPTISM.

Bathing is a practice of antiquity. The Greeks, as early as the heroic age, are said to have bathed themselves in the

sea, in rivers, &c. We even find mention in Homer of hot baths in the Trojan times; but these seem to have been very rare, and only used on extraordinary occasions. Athenæus speaks of hot baths as unusual even in his age. In reality, public baths appear to have been discouraged, and even prohibited, by the ancient Greeks, who were contented to wash themselves at home in a sort of bathing tubs. Pott. Archæol. tom. i. lib. iv. c. 19. The method of bathing among the ancient Greeks, was by heating water in a large vessel with three feet, and thence pouring it on the head and shoulders of the person seated in a tub for that purpose, who, at coming out, was anointed with oil. Burette, in Hist. Acad. Infer. tom. i. p. 117.

The Romans were also long before they came into the use of baths: the very name of which, *therma*, shews they borrowed it from the Greeks. As the ancient Romans were chiefly employed in agriculture, their custom was, every evening, after work, to wash their arms and legs, that they might sit down to supper with more decency: for it is to be observed, the use of linen was then unknown, and the people of that age went with their arms and legs bare, and consequently exposed to dust and filth. But this was not all; for every ninth day, when they repaired to the city, either to the *naumina*, or to attend at the assemblies of the people, they bathed all over in the Tyber, or some other river which happened to be nearest to them. This seems to have been all the bathing known till the time of Pompey, when the custom began of bathing every day. Mercurial. de Art. Gymn. lib. i. c. 10. Mem. Acad. Infer. tom. ii. p. 414.

The Celtic nations were not without the use of bathing: the ancient Germans bathed every day; in winter in warm water, and in summer in cold. This is what Tacitus seems to suggest, "statim e somno—lavantur, læpius calida, aut apud quos pluvium hiems occupat." De Mor. Ger. cap. 22.

Bathing, among the ancients, made a part of diet, and was used as familiarly as eating, or sleep; and cold bathing was in high esteem among their physicians for the cure of diseases; as appears from Strabo, Pliny, Hippocrates, and Oribasius: whence occur frequent exhortations to washing in the sea, and plunging into cold water. The first instance of cold bathing, as a medicine, is Melampus's bathing the daughter of the king of Argos; and the first instance of warm bathing, is the use of it by Medea, who was said to boil people alive, because Pelias king of Thessaly died in a warm bath under her hands. The cold bath was successfully used by Antonius Musa, for the recovery of Augustus; but after the death of Marcellus, who was thought to have fallen a sacrifice to the improper use of it, the practice sunk into neglect. It was again revived towards the close of the reign of Nero, by a physician of Marseilles named Charmis; but it was afterward disused during the ignorance of the succeeding ages. Among the Turks, bathing forms a part of diet and luxury; and in every town, and even village, there is a public bath, for those who have not the convenience of private baths attached to their own houses. Paron de Tott (Mémoires) gives us the following account of the construction of the private baths. Two small chambers, built with brick and faced with marble or plaster, communicate with each other, and each of them is enlightened by a small cupola cut in chequers. This little edifice is commonly joined to the house by a small room, in which those who bathe undress: double doors, sliding over and lifted with felt, shut in the first and second part of the stove. A wood fire is kept in a subterranean vault, the entrance into which is from without. This fire-place is under the farthestmost chamber, and heats a caldron immediately beneath the marble floor, which serves

as a ceiling to the vault. Pipes, placed within the walls, proceed from the inside of the caldron, and go out at the cupola, for the purpose of evaporating the water, which is kept continually boiling. Other tubes, communicating with a reservoir, are likewise contained within the brick work, and furnish the inside with cold water, by means of cocks placed at the side of those which yield the warm water. Small seats of smooth wood are made to fit on, and drains cut in the marble to carry off the water which is thrown down. These private baths, always heated twenty-four hours before they are used, by being thus constructed, possess such a degree of heat, that persons, who undress in the exterior chamber, and put on high sandals of wood to preserve the feet from being burnt by the marble floor, cannot enter the first room with safety till they have stopped a moment between the two doors, to let the lungs dilate; after which they cannot enter the second stove, under which the heat is most active, without similar precaution. A sudden perspiration rushing through all the pores, is felt immediately as they are entered; but the violence of this heat does not prevent the women from staying in these baths five or six hours, and returning to them very frequently. The following description of the public bath, and the method of using it, is abstracted from the account given of the baths at Cairo by Savary, Travels, vol. i. p. 146, &c. The first apartment, or undressing chamber, is a lofty and spacious hall, which rises in the form of a rotunda, and is open at the top for admitting a free circulation of the air. A spacious estrade, or raised floor, covered with a carpet, and divided into compartments, goes round it, on which the person who bathes lays his clothes. In the middle of the building, a jet-d'eau spouts up from a basin, and agreeably entertains the eye. When you are undressed, you tie a napkin round your loins, put on a pair of sandals, and then enter a narrow passage, where you begin to feel the heat. The door being shut, at the distance of twenty paces you open a second door, and proceed along a passage, which forms a right angle with the former: here the heat increases. Those who are afraid of suddenly exposing themselves to a stronger degree of it, stop in a marble hall, in the way to the bath, properly so called. The bath itself is a spacious and vaulted apartment, paved and lined with marble, around which are four closets. The vapour, incessantly rising from a fountain and cistern of hot water, mixes itself with the burning perfumes, when perfumes are desired by the persons who bathe. The bathers, extended on a cloth that is spread out, and with the head supported by a small cushion, stretch themselves freely in every posture, whilst they are enveloped by a cloud of odiferous vapours, which penetrate into all their pores. After reposing there for some time, till a gentle moisture is perceived over the whole body, a servant presses you gently, turns you over, and when the limbs are become supple and flexible, he makes all the joints crack without any difficulty. He masses, i. e. delicately touches, and seems to knead the flesh, without making you feel the smallest pain. When this operation is finished, he puts on a glove covered with a piece of coarse stuff, and rubs you for a long time: and during this operation, he detaches from the body, running with sweat, a scurf or sort of small scales, and removes even the imperceptible filth that stops the pores. The skin becomes soft and smooth like satin. He then conducts you into a closet, pours a lather of perfumed soap upon your head, and then withdraws. The closet is furnished with a cistern and two cocks, one for cold and the other for hot water. After having washed in this apartment, the servant brings a depilatory pomatum, composed of a mineral called "ratina," which is of a deep brown, and which the Egyptians burn lightly, knead with water, and mix with half the quantity

quantity of slaked lime. This greyish paste, applied to the hair, makes it fall off in a little time; and it is generally used both by men and women in Egypt. After being well washed and purified, you are wrapped up in hot linen, and conducted through the windings that lead to the outer apartment: and by this gradual transition from heat to cold, or by stopping for some time in the hall next the stove, no inconvenience arises from the use of the bath. On arriving at the estrade, you find a bed prepared for you, and as soon as you are laid down, a child presses every part of the body with its delicate fingers, in order to dry you thoroughly. Here you change linen a second time, and the child gently grates the callosity of your feet with pumice stone. He then brings you a pipe and Mocha coffee.

By these baths, says Savary, the use of which the ancients strongly recommended, and which are still the delight of the Egyptians, they prevent or dispel rheumatism, catarrhs, and such cutaneous disorders as are produced by want of perspiration. Thus the blood is made to circulate with freedom, the whole body acquires a suppleness and lightness, and the spirits gain a vivacity and flow, which are not experienced in an equal degree by those who do not pay so much attention to external cleanliness. The women are particularly fond of these baths, and frequent them at least once a week. After undergoing the usual preparations, they wash their bodies, and more especially their heads, with rose-water. Here the female head-dressers form their long black hair into tresses, to which they apply costly essences, instead of powder and pomatum. Here they blacken the edges of their eye-lids, and lengthen their eye-brows with "cohel," or a preparation of tin burnt with gall-nuts. Here also they stain their finger and toe nails with "herme," (See *ALCANNA*), which gives them a golden colour. The linen and clothing which they use are passed through the sweet steam of the wood of aloes. The days, appropriated to the use of the bath, are festivals for the Egyptian women; and on this occasion they pay great attention to the ornaments of their dress, as well as to the cleanliness of their persons.

Baths similar to that above described, though differing in size, are constructed in all the principal towns of Egypt. The necessity of cleanliness in the eastern climates, where perspiration is so copious, has rendered baths indispensable: the comfort they produce preserves the use of them; and Mahomet, who knew their utility, has re-enforced the practice of ablution and bathing by express precept.

Mr. Tooke (*View of the Russian Empire*, vol. ii. p. 7, &c.) informs us, that the common Russians, in general, use but few medicines; supplying their place in all cases by the sweating bath, a practice universal among them, and which has a decided influence on the whole physical state of the people. The use of the bath, that venerable relief of the manners of the ancient world, as this ingenious writer denominates it, is now almost entirely confined to the Oriental nations, where it ministers both to health and to luxury, and is perpetuated by religion. In Europe it has been gradually declining for several centuries, though it was here also in some sort interwoven with religion, the holy water of the Roman catholic church being a slight remnant of it.

Russia and Hungary are at present the only countries in this quarter of the world, where it is still the custom to bathe after the manner of the ancients. In Russia particularly the bath forms so essential a part of the system of living, that it is used by people of every age, and in all circumstances, by infants, by lying-in women, in almost all sicknesses, before and after a journey, after hard work, &c. The bath is a necessary of life so indispensable to the common people, that they frequent it as often as possible, well or ill, and without

any particular occasion, once a week at least. Persons of middle station in good circumstances, and the great, usually construct vapour baths, after the Russian fashion, in their own houses, though in these classes the practice is declining under the increasing influence of foreign manners. Baths have been common in Russia from time immemorial. They are described by Nestor so long ago as the 11th century, precisely in their present form. Among the ancients the baths were public buildings, under the immediate cognizance of the government. The invention of them was owing to cleanliness and convenience; but in process of time all the graces of architecture were lavished upon them; and at length luxury and voluptuousness so perverted them from their primitive purposes, that they became offensive and shocking to the moralists of antiquity. Alexander was astonished at the magnificence of the baths in Persia. At Rome, under the emperors, there were once 870 of these edifices, such, with respect to magnificence and taste, as might pass for master-pieces of art; and in after ages they were demolished by the Goths, or converted by bishops into churches. In our days, however, Hungary is the only country that can still exhibit baths, equal in magnificence to those of the ancient Romans. In Russia, on the contrary, they are always of that simple construction, which indicates their primitive and most essential destination. Here the public baths, called public because they are under the care of the police, and let out to common people on the crown's account, usually consist of mean wooden houses, situate, whenever it is possible, by the side of a running stream. In the bath-room is a large vaulted oven, which, when heated, makes the paving stones lying upon it red-hot; and adjoining to the oven is a kettle fixed in masonry, for the purpose of holding boiling water. Round about the walls are three or four rows of benches one above another, like the seats of a scaffold. The room has little light, but here and there are apertures for letting the vapour escape; the cold water that is wanted being let in by small channels. Some baths have an anti-chamber for dressing and undressing; but in most of them this is done in the open court-yard, which on that account has a boarded fence, and is provided with benches of planks. In those parts of the country where wood is scarce, they sometimes consist of wretched caverns, commonly dug in the earth close to the bank of some river. In the houses of wealthy individuals, and in the palaces of the great, they are constructed in the same manner, but with superior elegance and convenience. The heat in the bath-room is usually from 32° to 40° of Reaumur; and this is much increased by throwing water every five minutes on the glowing hot stones in the chamber of the oven. Thus the heat often rises, especially on the uppermost bench, to 44° of the thermometer. The persons that bathe lie quite naked, on one of the benches, where they perspire more or less in proportion to the heat of the humid atmosphere in which they are enveloped. For promoting perspiration, and more completely opening the pores, they are first rubbed, and then gently flagellated with leafy bunches of birch. After remaining for some time in this state, they come down from the sweating bench, and wash their bodies with warm or cold water, and at last plunge over head in a large tub of water.

Many persons throw themselves immediately from the bath-room into the adjoining river, or roll themselves in the snow in a frost of ten or more degrees.

The Russian baths are, therefore, "sweating baths;" not the Roman tepidaria or caldaria of a moderate warmth, but very violent sweating-baths, which to a person unhabituated to the practice, bring on a real, though a gentle and almost voluptuous swoon. They are "vapour-baths," not

water nor yet by sweating-baths; differing in this respect from all the baths of antiquity, as well as from those of the modern Orientals; and in this consists their essential excellence, that they are beneficial in such a variety of cases, where hot-water-baths would be useless or even pernicious. They are further "sedatory baths," as they promote cleanliness, assist the perspiration, render the skin soft and smooth, &c. and not voluptuous baths like those of the Greeks and Romans. All the inventions of effeminacy and luxury are entirely obviated; and of anointing after the use of the bath, indispensable in those, the Russian is wholly ignorant. Instead of this the sudden transition from heat to a rigorous frost hardens his body, and adapts it to all the severities of climate, and to every vicissitude of weather; a transition which seems to us unnatural or dangerous; merely from the prejudices of a soft and effeminate age.

Mr. Tooke adds, that, without doubt, the Russians owe their longevity, their robust state of health, their little disposition to certain mortal diseases, and their happy and cheerful temper, mostly to these baths, though climate, aliment, and habits of living likewise contribute their share.

The great lord chancellor Bacon, and other sagacious observers of nature, and of mankind, have lamented, and certainly not without cause, that the practice of bathing has fallen into disuse among the modern nations of Europe, and anxiously wish that it might again revive in all our towns and villages. In fact, when we consider, says Mr. Tooke, that the old physicians so early introduced into their practice this remedy of nature's own invention, and employed it with such great success; when we recollect that Rome for 500 years had no physicians but only baths, and that to this day a multitude of nations cure almost all their maladies merely by baths; we cannot avoid regarding the dismission of them as the epocha of a grand revolution, which has been wrought in the physical state of the human race, in one quarter of the world. The natural perspiration, the most important of all excretions, must naturally go on better in a body constantly kept soft by bathing. Many impurities that privily lay in us the train to tedious and dangerous distempers are removed in time, before they poison the blood and juices. All exanthematic diseases are abated by bathing, and consequently the small-pox; and if this dreadful disorder be actually less fatal in Russia than in other countries, this phenomenon need not be attributed to any other cause besides vapour-baths.

BATHING, *medicinally considered*, ranks among the most efficacious means by which diseases are prevented or cured. Its effects vary according to the variation of temperature, and according to the qualities of the liquid medium employed: that is, according as the bath consists either of common water, or of water containing salt or other mineral ingredients (see MINERAL WATERS), or of water impregnated with the virtues of aromatic or other herbs. These last, which go under the name of *medicated baths*, are seldom used; and when they are, we are inclined to believe that it is to the watery medium, rather than to such impregnations, that their beneficial operation is to be ascribed.

Under the present head, we shall confine ourselves to the consideration of the effects produced by bathing, so far as they depend upon a diminution or increase of temperature above or below the natural standard of the human body.

Baths of different degrees of temperature, corresponding to the familiar terms, *cold*, *temperate*, and *hot*, are suited to different and opposite states of the body. The manner of using them is also different; the time of immersion or staying in them varying according to the difference of temperature,

and according to the required quantum of impression or effect, as will be particularly noticed in treating of each.—And, first, of the

COLD BATH, by which is understood water of a temperature from 65 to 70 of Fahrenheit. The general effects produced in a healthy person by immersion into an ordinary cold bath (that is, water of the temperature of 48 or 50) are, according to the accurate statement of Dr. Saunders, as follow: "First, there is a general sensation of cold, forming that sudden shock to the whole system, which is one of the most important effects of the cold bath. This is almost immediately succeeded by an equally universal sense of warmth, which increases rapidly to a certain point, so as to cause the surrounding water, though actually cold, to feel of a comfortable warmth; and this feeling is sooner produced, and continues longer, in proportion as the person is in full health, and naturally possesses a vigorous circulation. By degrees, however, if the body continues immersed, it becomes chilled; violent shivering comes on; the extremities grow numb and pale; sometimes sickness takes place; and, at last, the animal powers are exhausted by cold and fatigue. In this process, the most remarkable effects are those which occur first, and are directly consequent to the shock of immersion; and these require particular attention in a medical view, as it is only to the production of these that the cold bathing should be suffered to proceed. The sensations of returning warmth which take place directly after the cold of the first immersion, constitute what has been called the *reaction of the system*; and this is certainly a proper and characteristic term, as it imports an action produced in the body itself, to resist an external impression. Reaction in this place seems to be a peculiar effort of the living power, and to be excited in a degree proportionate to the force of that power, and to the intensity of the cause which called it into action. It implies not merely an increase of the production of animal heat, but, superadded to this, a sudden effort within the body, and the whole arterial system, to overcome an impression on the extremities as sudden and powerful. Hence it is, that a mere abstraction of heat, by a cold medium, will not produce that which is precisely meant by reaction, except the external cold be applied suddenly, and to a large surface. These two conditions are fulfilled by sudden immersion into cold water. The superior power of conducting heat which water possesses over air, is also a circumstance that is always to be kept in mind in applying cold externally. This is particularly shewn where a person continues long in this cold medium beyond the first effects of reaction. On account of the high conducting power of water, the body must be constantly employed in producing an unusual quantity of heat; and this appears to be a great effort in the constitution, which, if carried too far, goes directly to destroy the animal powers." Thus three effects are produced by immersion in cold water; viz. an instantaneous and powerful shock, a sudden abstraction of heat from the surface of the body, and that exertion of the vital energies to counteract the shock and restore the lost quantity of animal heat, which is termed reaction. It is easy to perceive, that when the body is placed under such circumstances for a few seconds, a considerable impression must be made, first, upon the sentient system, i. e. the brain, and its ramifications, the nerves; and, secondly, upon the sanguiferous and absorbent systems: and that such impression may be rendered subservient to the prevention and cure of various diseases. Accordingly, the cold bath is a principal remedy, first, in many convulsive affections, and in maniacal attacks; and, secondly, in certain forms and conditions of fever.

1. In the convulsions to which children are so liable, Dr. Currie of Liverpool (whose observations on the subject of cold bathing cannot be too often quoted) has found this application a most useful remedy, whether the convulsions originated in worms, or other causes. In early infancy, however, he remarks, that he has used it with caution, sometimes tempering the water when the weather was cold, and sometimes pouring it upon the patient, rather than immersing the patient in it; making the application of the cold water in this way sudden and transient, so as to secure reaction, and avoiding the remedy entirely in all cases where the vital energy seemed much exhausted. He further remarks, that the chief benefit derived from the cold bath in convulsive diseases, depends on its being used in the paroxysm of convulsion. It not only shortens the duration or abates the violence of the existing paroxysm, but has a remote good effect in retarding or wholly preventing its return. In that convulsive disorder termed *chorea Sti. Viti*, the cold bath, though strongly recommended by most practitioners, has not succeeded with this author; and he candidly acknowledges, that his experience of its effects in epileptic fits is as yet too limited to enable him to form any satisfactory conclusion. The late Dr. Heberden, whose experience in these affections was considerable, had no great opinion of it. Against *tetanus*, whether idiopathic or arising from local injury, this remedy has been employed with the most decided good effect, particularly in the tropical climates; nor has it proved less beneficial in maniacal paroxysms. See Dr. Currie's work hereafter quoted.

2. In certain forms and conditions of fever. In these cases, cold bathing, whether by immersion or affusion, is of eminent service when properly applied; as, by abstracting the preternatural degree of heat, it rids the body of an exhausting stimulus and irritation, and thereby abates the frequency of the pulse, the delirium, and other febrile symptoms. It may be resorted to in most fevers (some of the exanthematous fevers excepted) where the skin is hot and dry; but it is especially adapted to the *typhus* or common contagious fever of this country, the ardent fevers of the hot climates, and the yellow fever of the West Indies, &c.—“The safest and most advantageous time (says Dr. Currie) for using the aspersion or affusion of cold water, is when the exacerbation is at its height, or immediately after its declination is begun; and this has led me almost always to direct it to be employed from six to nine o'clock in the evening; but it may be safely used at any time of the day, when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration.” It is of the utmost importance that medical practitioners be careful not to apply this remedy during the cold fit of fever, when it would extinguish life; nor to apply it when the heat of the body is less than natural, or even only equal to the natural heat; nor when the fever-patient is in a state of perspiration. Cold bathing has also been tried in the *scarlatina*; but in this species of eruptive fever as well as in measles, the application of cold water to the surface of the body is, in our opinion, by no means advisable. Another caution we would subjoin with regard even to fevers that are not eruptive; viz. that when they are complicated (as often happens in this climate) with pneumonic inflammation, cold ablution is inadmissible.

Cold bathing has often been recommended in certain glandular diseases, and particularly in scrophula. Accurate observation, however, has proved, that in these cases it is generally hurtful; and that for such complaints, a temperate bath, whether of fresh or salt water, is preferable.

Having thus described the general effects of cold bathing, as well as its particular application to certain states of disease; we have only further to add a few words respecting the manner of using it. In the case of *immersion*, the time of staying should in general not exceed a minute or two, where the degree of cold is below 60; but in the summer and autumnal seasons, immersion in rivers, and especially in the sea, may be continued as long as is pleasant to the feelings of the bathers; provided the body is at the same time exercised in swimming. Much mischief, however, is frequently done by staying in too long.

It has been commonly supposed, that if a person has made himself warm with walking or any other exercise, he must wait till he becomes cooled before he should plunge into the cold water. Dr. Currie, however, has shewn that this is an erroneous idea, and that in the earlier stages of exercise, before profuse perspiration has dissipated the heat, and fatigue debilitated the living power, nothing is more safe, according to his experience, than the cold bath. This is so true, that he has for some years constantly directed infirm persons to use such a degree of exercise before immersion, as may produce some increased action of the vascular system, with some increase of heat; and thus secure a force of reaction under the shock, which otherwise might not always take place. The popular opinion, that it is safest to go perfectly cool into the water, is founded (he observes) on erroneous notions, and sometimes productive of injurious consequences. Thus, persons heated and beginning to perspire, often think it necessary to wait on the edge of the bath until they are perfectly cooled; and then plunging into the water, feel a sudden chilliness that is alarming and dangerous. In such cases, the injury is generally imputed to going into the water too warm, whereas in truth it arises from going in too cold.

Besides immersion, there are other modes of cold bathing; such as *affusion*, which consists in suddenly pouring upon the body a sufficient quantity of cold water from buckets or other vessels. This mode of applying cold water produces a very considerable shock, and consequent reaction. It is this mode of cold bathing that has been resorted to with advantage in the contagious fevers of this climate, and in the yellow fever of the West Indies. What is termed the shower-bath is only another mode of affusion.

As cold bathing is a remedy which is successfully employed for the cure of various disorders, so is it a preservative against others, and particularly against febrile infection. When used by persons in health, it increases the tone of the muscular fibre, strengthens the digestive organs, and by diminishing the sensibility of the whole system, and particularly of the skin, renders the body less susceptible of atmospheric impressions from cold, wet, and sudden changes of temperature; thus contributing to the production of what is termed a robust or athletic constitution. A temperate bath (i. e. from 70 to 85, or more) is applicable to the same cases as the cold bath, and may be used in the same manner. It is preferable in many cases where the shock of the ordinary cold bath is too great.

If after going into the cold bath a person feels dull or chilly, or complains of head-ach or tightness across the chest, it is a proof that it disagrees, and it should accordingly be discontinued. It should further be remarked, that this remedy is not suited to those who have a tendency to consumption, nor to such as are constitutionally liable to bowel complaints. The best seasons of the year for cold bathing are the summer and autumn.

We now proceed to the consideration of

WARM BATHING: a remedy not less efficacious than the former in diseases of an opposite nature; but concerning

concerning the operation of which, wrong notions have till very lately been entertained by the generality of medical writers and medical practitioners. It has been imagined that the warm bath relaxes (a figurative expression) and weakens, whereas it produces a contrary effect; unless indeed the temperature be so high, or the time of immersion continued so long, as to bring on that degree of debility which is accompanied with delirium. But this arises only from an abuse of hot bathing, and is even then the consequence of an excess of stimulation. So far is immersion of the body in water heated to 96 from having a lowering or weakening operation, that when duly regulated it is found to raise the spirits, to mend the pulse and appetite, and to refresh and invigorate the whole frame. Hence the benefit derived from it after great fatigue; in old age; in atonic gout, accompanied with stiffness and pallid swellings of the joints; in paralysis; in chlorosis, in diseases arising from a certain torpor of the lymphatic and glandular system, such as scrophula, leprosy and other chronic eruptions, &c. In cases of predisposition to phthisis, it abates the frequency of the pulse, and tends to retard at least, if it does not wholly prevent, the pulmonary affection. In consequence of its soothing and agreeable impression upon the surface of the body, it produces very beneficial effects in certain disordered states of the alimentary canal, originating in diminished action; and it affords the best and speediest relief in a great variety of painful disorders, whether connected with local inflammation or not; such as chronic rheumatism, certain forms of lues venerea, nephritis, calculus vesicae, colic, enteritis, &c.

The time of immersion should be varied according to the temperature of the water, and the feelings of the patient. In a bath of 96, a person may remain fifteen, twenty, or thirty minutes, or even longer; but in one of 98 or 100, it will seldom be proper, and indeed there are few persons that can bear, to remain beyond ten minutes, and in the generality of cases not so long. Patients labouring under chronic rheumatism and palsy bear the high degrees of temperature best. When sweating is desired (which will seldom happen except in cases of local inflammation), the warm bath should be used in an evening, and the patient should immediately afterwards be put into a warm bed, and remain there until late the next morning: but in all other cases, where sweating is not required, or in which it would be hurtful, the best time for using the warm bath will be in the forenoon, about two hours after breakfast. In these cases, the bathers should not retire to bed, nor confine themselves within doors, but go about as usual; unless the weather should be particularly damp or inclement. Hot bathing, like cold bathing, is applied topically by pumping on the diseased part, as will be described when we come to treat on mineral waters. Sometimes steam is applied to the body instead of warm water. See VAPOUR BATH.

Among the works on cold and warm bathing, the following are those which seem most entitled to notice: viz. "Floyer on Cold Bathing," 1709. It should be remarked, however, that this author writes without method on this subject; that he is too indiscriminate in his praises of the cold bath, and that he recommends it in some diseases of debility to which warm bathing is better adapted. "Marsard über die Natur und den Gebrauch der Bäder." Hanover, 1793. Currie's "Medical Reports on the Effects of Water, cold and warm," 1797. And the 6th chapter of Dr. Saunders's "Treatise on Mineral Waters," 1800.

BATHING *a lusk* or *faleon*, is, when being weaned from her ramage fooleries, and also hired, rewarded, and thoroughly reclaimed, she is offered some water to bathe her-

self in, in a basin, where she may stand up to the thighs, choosing a temperate clear day for that purpose. By the use of bathing she gains strength, with a sharp appetite, and so grows bold.

BATHING, among the Cophts and Æthiopians, denotes the day of Christ's baptism, reputed the 6th of January; when, from an opinion of an extraordinary sanctity in the waters on that day, they not only, by ancient custom, baptized their catechumens, but were re-baptized themselves. The water of this day they carry home to keep; and Chrysofom assures us, that it had been often known to remain sweet and uncorrupted for two or three years. Orat. 74.

BATHING-TUB. In the Roman baths there are two kinds of bathing-tubs; the one fixed, and the other moveable. Among the latter, some were contrived in purpose to be suspended in the air; whereby, to the pleasure of bathing was added that of being swung or rocked by the motion given to the bathing-tub. Burette, in Hist. Acad. Inscript. tom. i. p. 122.

BATHINUS, in *Ancient Geography*, a river of Pannonia, near which the young men of the country assembled, laid down their arms, and threw themselves at the feet of the victorious Romans.

BATHIS, BATHUM, a river of Asia, in the territory of Colchis, which ran from the east to the west, and discharged itself into the Euxine sea, 6 leagues south of the mouth of the Phasis.

BATHIS, in *Entomology*, a species of PABILIO (Pleb. rur.) that inhabits Surinam. The wings are two-tailed, with a black ocellar spot; beneath brown, fasciated with white; anal angle rufous. Fabricius.

BATHMONSTER, in *Geography*, a town of Hungary, separated by the Danube from BATHA.

BATHOS, in *Ancient Geography*, a town of the Peloponnese, in Arcadia, near the river Alpheus, according to Pausanias; who adds, that they celebrated every third year the mysteries of the greater goddess in this place.

BATHRACUS, a port of Africa, in Marmarica. Ptolemy.

BATHRITITES, the name of a nome of Egypt, whence, according to Eusebius, king Vaphres sent succour to king Solomon.

BATHRUM, a name given by ancient surgeons to a kind of stool or bench proper for the reduction of dislocated bones. This is called *βελτον* *ἰπποκράτειον*, or the *Hippocratic stool*. Its description and use are represented at large by Schullterus, Arm. Chir. p. i.

BATHURST, RALPH, in *Biography*, born at Howtherpe, a small hamlet belonging to the parish of Theddingworth in Northamptonshire, in the year 1620, received the rudiments of his education at the free-school in the city of Coventry; where his progress in the Latin and Greek languages was so rapid and extensive, that he was sent to Oxford, and entered in Gloucester Hall (now Worcester College), October the 10th, 1634, being then only fourteen years of age. He was however soon removed to Trinity College, where his father had been educated, and of which two of his brothers, George and Edward, were then members. Proceeding in his studies, he was elected scholar of the college, June 5th, 1637. In January following he took his degree of Bachelor of Arts; and in the year 1640, he was appointed Fellow of the College. In 1641, he proceeded Master of Arts; and in 1644, was ordained priest by the bishop of Oxford; his inclination, his biographer says, disposing him to theological studies. Finding however, from the troubles that then and for many years after afflicted the country

country, little prospect of advancing himself in that line, he applied to the study of medicine, which, in a letter to a friend some years after, he called "his refuge in bad times, and not his primitive design." But as his mind was vigorous, he soon acquired considerable eminence in this profession; being assisted in his endeavours by Dr. Thomas Willis, with whom he kept up an intimate connection until death deprived him of that valuable friend. In 1654, he took the accumulated degrees of Bachelor and Doctor in Medicine; but he had before so far signalized himself, as to obtain the appointment of physician to the sick and wounded of the navy, which office he performed to the satisfaction of the commanders of the ships, and of the admiralty. Quitting this situation, he returned and settled in Oxford; and, with his friend Dr. Willis, attended Abingdon market regularly every Monday, to give advice to such patients as applied. He was an associate with Mr. Boyle, Dr. Seth Ward, Christopher Wren, and various other persons, who met every week at the rooms of Dr. Wilkins, to discuss philosophical subjects; which meetings led to the formation of the Royal Society in London, in 1662. A committee or branch of the society continued their meetings at Oxford for several years after, of which Dr. Bathurst was elected president in 1688. On the restoration of king Charles the Second, he quitted the practice of medicine, and resumed his theological studies. In 1663, he was made chaplain to the king; and the year following, president of the college, which was nearly rebuilt under his direction. The expence of the building was furnished in part by the college, part by subscriptions solicited by the doctor, and no small portion of it from his own fortune. About the same time he married the widow of Dr. John Palmer, warden of All Souls College; but had no children by her. In 1670, he was installed dean of Wells. This advancement was procured him by the duke of Devonshire, to whose notice he had recommended himself by an elegant copy of Latin verses to Mr. Hobbes, on his treatise of Human Nature, which was printed with the volume. In 1673 he was made chancellor of the university, and was re-elected to that office the two following years, by which means he had opportunity of reforming many abuses which had crept into the institution, and of establishing many useful regulations which still continue to be observed. As he had contributed largely in rebuilding and beautifying his own college, and was the first in introducing Grecian architecture in Oxford, he now set about restoring St. Mary's church, which had suffered much during the protectorate. He subscribed 300*l.* towards paving the choir with marble, and erecting an organ there. In 1691, he was nominated by king William and Queen Mary, bishop of Bristol, with liberty to keep his deanery and headship of the college; but had the resolution to decline this noble offer, lest it should detain him, he said, too long from the university, and be the means of retarding the improvements he was making there, both in discipline and in the buildings. In the mean while his fame for proficiency in letters became so extended, that he corresponded with most of the first literary characters in the kingdom, who frequently submitted their works to his inspection and criticism before they were published. He was particularly instrumental in advancing Derham, the celebrated author of the "Astro," and "Physico-Theology," from obscurity and indigence; recommending him to the bishop of Salisbury, through whose means he was raised to an eminent station in the church. As he was a strict disciplinarian, and regularly attended his duty both in the university and at his deanery, he had little leisure for undertaking any extensive works; accordingly, excepting his "Prelectiones

tres de Respiratione," we have only his "Orations" before the university, on his being appointed vice-chancellor, on laying down his office, and on a few other subjects; with some short poems. These however have been sufficient to establish his character as an elegant Latin scholar. He was very abstemious in his diet, and regular in taking exercise; and had the happiness of enjoying an almost uninterrupted state of good health until he was upwards of fourscore years of age; when his sight began to fail, and at length he became blind. Walking one day in his garden, the only amusement that remained to him after the failure of his sight, he had the misfortune to break his thigh bone, by what accident it is not said; which occasioned him excessive torture, and after languishing a few days, he died in 1704. His property, which was considerable, he had directed by his will to be disposed of in the manner he had expended a large part of his income in his lifetime; in donations towards improving his college; in books and medals to different libraries; in donations to the cathedral at Wells, and to the servants of the cathedral and of his own college. The remainder was left among his relations, who were numerous. His directions concerning his funeral, as being singular, and marking somewhat the disposition of the man, we shall transcribe.—"Concerning the place and manner of my funeral (he says) I am not at all solicitous, but shall leave it to the discretion of my executor; except it shall please God to give me leisure and opportunity of ordering it at the time of my death, as occasion may then require: only I shall always desire, that it may be performed with all convenient frugality and privacy; and that my mouth and nostrils may be firmly closed up with a plaster of diachylon, and my whole head wrapped in cere-cloth; and that I be buried without any cover to my coffin, only with a black pall of woollen stuff loosely nailed on, and hanging loose down." See Life of Ralph Bathurst, by T. Warton.

BATHURST, ALLEN, earl Bathurst, a nobleman not more distinguished by the elevation of his rank, than by his abilities and integrity as a statesman, and by the elegance of his taste and the variety of his accomplishments as a polite scholar, was the son of Sir Benjamin Bathurst, descended from an ancient family of Lunenburg, residing at a place called "Batters;" and settled in England in the time of the Saxons, at a place called "Batters Hurst," or Batters Grove, in Sussex, whence the name; and born in Westminster, in the year 1684. At the age of 15 years, he was entered in Trinity College, Oxford, where he enjoyed peculiar advantages for improvement under his uncle, dean Bathurst, who was then president. Having availed himself in an eminent degree of these advantages, he commenced his political career as a senator in 1705, being chosen representative for the borough of Cirencester in Gloucestershire, which he served in two parliaments. Under this character he distinguished himself in the debates that related to the union of the two kingdoms, and vigorously supported this measure. He likewise concurred in the opposition planned by his two friends, Mr. Harley and Mr. St. John, against the duke of Marlborough and his adherents; and by his spirit and eloquence he was of great service to his party. At the same time he was duly sensible of the merit of those from whom he differed in political principles; and by his conduct toward lord Somers, both in and out of office, he preserved his lordship's esteem and friendship. In his opposition to the whig ministry, he appears to have acted from the conviction of his own mind; for after their dismissal, he accepted no place under government, though his abilities and activity entitled him to notice, and his connection with the principal Tories of that period might naturally have led him to expect some honourable

able and lucrative preferment. However, his merit was recompensed in 1711, by advancement to the dignity of a peer of Great Britain, under the title of lord Bathurst, baron Bathurst of Battleleden in the county of Bedford. Upon the accession of king George I. the political friends of his lordship were in disgrace, and some of them were actually exposed to the prosecution of government; and yet his attachment to them remained firm and unchangeable. He even showed his disapprobation of the treatment they suffered, which he considered as severe and vindictive; and on this occasion he is said to have observed, in strong and poignant terms, "that the king of a faction was only the sovereign of half his subjects." His zeal in defence of his friends was manifested by his joining in the protests against the attainder of lord Bolingbroke and the duke of Ormond; and by his opposing the prosecution, and concurring in the unanimous acquittal, of lord Oxford. In 1716, he opposed the septennial bill; and united with thirty peers in entering his reasons for dissenting from it, as a violation of the constitution. From the commencement of the year 1718, he took an active and distinguished part, for the space of twenty-five years, in every matter of importance that came before the upper house of parliament, and he steadily opposed the measures of the court, and the administration of sir Robert Walpole. Lord Bathurst was a zealous advocate for bishop Atterbury; and distinguished himself, in 1723, on the third reading of the bill for inflicting pains and penalties on that ingenious and celebrated prelate. In 1727, he opened the debate on the king's speech, and strenuously opposed a war with Spain, which then threatened the country. "What (said he) can we get by the war, if it be a successful one? I'll say it in one word, nothing. What can we lose, if it be unprosperous? I'll say it in one word, in a syllable, all." In the year 1731, he supported the bill against permitting pensioners to sit in the house of commons; he moved an address to the king for discharging the 12,000 Hessian troops in the pay of Great Britain; and in the next parliament, he very ably resisted the undue taxation of the poor, on the bill for the revival of the salt-duty. On another occasion he displayed his parliamentary talents, by the support of the earl of Oxford's motion for reducing the number of forces to 12,000 effective men, and vindicated the expedience and usefulness of a national militia, as the most proper and constitutional mode of defence in a free country. In a subsequent debate on the mutiny bill, his lordship declared himself, with great eloquence and spirit, against a large standing army, and in favour of a national militia. Among other things, he particularly urged the importance of all men in the kingdom, or at least all freeholders, farmers, and substantial merchants and tradesmen, providing themselves with arms, and training themselves to military discipline. He likewise declared his utter disapprobation of the method that had been adopted of alienating the sinking fund, and applying it to other objects besides the payment of the public debts. Lord Bathurst was uniform and active in opposing the measures of sir Robert Walpole's administration, particularly with regard to the transactions that regarded the Spanish depositions, and the convention with Spain, and the subsequent conduct of the war with that kingdom; and he exerted himself, with singular ability, in the debate that lasted two days, on the question, whether an address should be presented to the king for the removal of this minister from his majesty's presence and councils for ever. When his lordship had accepted a place, in conjunction with some of his friends, his reasoning, in 1743, in vindication of the propriety and necessity of retaining the Hanoverian forces in the service of England, was somewhat differ-

ent from the sentiments he had avowed on a former occasion; but he was probably led to approve and defend this measure by the critical situation of our foreign affairs, and argued in its favour from a conviction of its prudence and rectitude. Whatever opinions may be entertained of lord Bathurst's political principles, and of the general reasons upon which his opposition to the whig ministry was founded, the history of that period will furnish scarcely any character, in which we may discover less discrepancy of conduct than in that of his lordship. We shall close this brief recital of his political history with the testimony of an anonymous writer, who delivered it at a time in which his talents were in their full exertion and display. "Lord Bathurst, in all he says, carries along with him that conviction which arises from a warm sense of liberty and virtue, directed by great abilities and a most exquisite discernment. He was called to the house of lords by means of the Tory interest, upon a particular exigence of state; and therefore it might have been presumed, that he was entirely devoted to that party. Yet he has chosen his principles of government so happily from what is commendable in both parties, that, upon whichever side he speaks, he is always observed to lean to the extremes of neither." *Genl. Mag.* vol. x. p. 103.

Lord Bathurst was married, in 1704, to Catherine, daughter and heiress of sir Peter Apsley, by whom he had four sons and five daughters. Having resigned, in 1744, the office of captain of his majesty's band of gentlemen pensioners, to which he was appointed in 1742, his lordship was in no public employment till the year 1757, when he was appointed treasurer to the present king, then prince of Wales, in which office he continued till the death of George II. At his majesty's accession in 1760, he declined the acceptance of any employment on account of his age; but in consideration of his distinguished merit, he had a pension on the Irish establishment of 2000 l. a year. "As his lordship's abilities and integrity," says an impartial and candid biographer, "in public life, gained him the esteem even of his political opponent; so in private life, his humanity and benevolence excited the affection of all who were honoured with his more intimate acquaintance."—"To his other virtues lord Bathurst added all the good-breeding, politeness and elegance of social intercourse. No person of rank, perhaps, ever knew better how to unite "*Otium cum dignitate.*" The improvements he made round his seat at Cirencester were worthy of his fortune, and shewed the grandeur of his taste." In this respect Mr. Pope (*Works*, vol. ii. p. 170. ed. 1776.) paid him a just and fine compliment:

"Who then shall grace, or who improve the soil?

Who plants like Bathurst, or who builds like Poyle?"

The same excellent poet, in his epistle to Lord Bathurst on the use of riches, has no less justly expressed his lordship's knowledge of the right mode of employing a large fortune:

"The sense to value riches, with the art
To enjoy them, and the virtue to impart,
Not meanly, nor ambitiously pursued,
Not sunk by sloth, not raised by servitude;
To balance fortune by a just expence,
Join with economy, magnificence;
With splendour, charity; with plenty, health;
Oh teach us, Bathurst, yet unspoild by wealth!
'That secret rare, between th' extremes to move,
Of mad good-nature, or of mean self-love."

His lordship's wit, taste, and learning led him to seek the acquaintance of men of genius; and he was intimately con-

connected

acted with the eminent persons of this character who adorned the beginning of the last century. From the few letters of his lordship that have been published, it appears, that his correspondence was a real honour and pleasure to those who enjoyed it. To the close of his life he preserved his natural cheerfulness and vivacity; and he was always accessible, hospitable, and beneficent. He was fond of rural amusements; and enjoyed, with a philosophical calmness, the shade of the trees which he had planted. Till within a month of his death, he constantly rode out two hours in the morning, and drank his bottle after dinner, jocosely observing, that he never could think of adopting Dr. Cadogan's regimen, as Dr. Cheyne had assured him fifty years before, that he would not live seven years longer, unless he abridged himself of his wine. About two years before his death, he had a party of friends; and being loth to part with them at an early hour in the evening, when his son, the chancellor, wished to retire, he said to his companions in a sprightly manner, as soon as his son was gone, "Come, my good friends, since the old gentleman is gone to bed, I think we may venture to crack another bottle." In 1772, his lordship was advanced to the dignity of earl; and having lived to see his eldest surviving son several years lord high chancellor of Great Britain, and promoted to a peerage by the title of baron Apsley, he died in the 91st year of his age, after a few days' illness, at his seat near Cirencester, on the 16th of September, in the year 1775. Biog. Brit.

BATHUS, in *Entomology*, a species of *PAPILIO* (*Pleb. Rur.*), with entire, black wings, glossed with blue; beneath white, with numerous black dots, and a continued fulvous band. Fabricius. Inhabits Aultria. This is *Papilio Battus* of Schmettler, and *Papilio Telephii* of Esper.

BATHYCHRUS COLOR, in *Painting*, a term used by the Greeks to express what the Romans call *auferus color*. Such a colour was coarse and dull, and wanted the life of the florid colours. See *EVANTHI Colores*.

BATHYCOLPUS, in *Ancient Geography*, a bay and river of Europe, in the Thracian Bosphorus. Hesychius.

BATHYLLUS, and **PYLADES**, in *Biography*, the inventors of a new method of representing all kinds of theatrical pieces by dancing. Bathyllus was a freedman of Mæcenas, the object of his extravagant and licentious attachment; and in compliance with the wishes of Mæcenas, Augustus countenanced these players and their art. Bathyllus excelled as a comic, and Pylades as a tragic pantomime. They flourished under Augustus, about the year B. C. 18. From these two competitors for public fame in the respective departments of their art sprung two sects, each of which retained the name and preserved the manner and character of its master. The disciples of Bathyllus were called Bathylli, and those of Pylades were denominated Pyladæ. The Romans divided themselves into parties on account of these two pantomimes; and the interest of Bathyllus's was at one time so prevalent as to procure the banishment of Pylades. Upon his return Augustus recommended his behaving better for the future, and not attempting to divide the people into parties or factions. Pylades replied, "Cæsar, it is of service to you to have the people bused about Bathyllus and me." Gen. Diët. Crev. Hist. vol. i. p. 122.

BATHYLLUS, in *Ancient Geography*, a fountain of Arcadia, in the Ploponnesus, near Megalopolis. Pausanias.

BATHYMI, a people of Arabia Felix. Ptolemy.

BATHYS, a river of Phrygia Salutaris, which flowed in the north of this province, along the plain of the city Dorylæum, and discharged itself into the river Sangaris.

BATHYS, *Fiume Tayburò*, a river of Sicily, which runs into the gulf of Castell a Mare.

BATHYS, the name of a port of Ethiopia. Ptolemy.

BATTI, a people of India, on the other side of the Ganges. Ptolemy.

BATIA, a town of Italy, in the territory of the Sabines.

BATIA, a district of Attica, belonging to the tribe of Ægides.

BATIÆ, a town of Epius.

BATIANA, *Baix*, a town of Gaul, on the right side of the Rhine, according to M. d'Anville.

BATIANI, a people of Italy, placed by Ptolemy in Liguria.

BATILLUS, a musical instrument made of metal, in the form of a flass, furnished with metalline rings, which being struck, yielded a kind of harmonical sounds; used by the Armenians in their church-service.

BATINA, in *Ancient Geography*, a town of Asia, in Media. Ptolemy.

BATINUS, a town of Italy, in Picentinura.

BATIS, in *Botany*, *βῆτις*, the name of an herb which bears some resemblance to bramble, *βῆτις*, Pliny. Lin. gen. n. 1104. Reich. 1208. Schreb. 1503. Brown 356. Jacq. Amer. 260. Juss. 443. Class, and order, *doxia triandria*. Gen. Char. * Male. Cal. ament pyramidal; scales one-flowered, fourfold, imbricate. Cor. none. Stam. filaments four, erect, longer than the scales of the ament; anthers oblong, twin, incumbent. * Female, on a separate plant. Cal. ament common fleshy, containing some floccules conglobated into an ovate, quadrangular body; involucre, two-leaved. Cor. none. Pist. germ quadrangular, fastened to the ament; style none; stigma two-lobed, obtuse, villose. Per. berry conjoined with the rest, one-celled. Seeds, four, triangular, acuminate.

Ess. Char. Male. Ament four-fold, imbricate. Cal. and Cor. none. Female. Ament ovate; involucre two-leaved. Cal. and Cor. none. Stigma two-lobed, sessile; berries conjoined, four-seeded.

Species, 1, *B. maritima*. Sloan. Jam. 1. 144. Kali. This is a shrub about four feet high; stems brittle, round, ash-coloured, branched, diffused, procumbent; young branches, four-cornered, four-furrowed, green, opposite and upright; leaves oblong, acute, drawing to a point towards the base, fleshy, succulent, flat above, convex beneath, sessile, opposite, scarcely an inch long, numerous; stigma white; fruits yellow or greenish-yellow. The whole plant is very salt to the taste; and is burnt for barilla at Carthagenæ, &c. A native of the Caribbee islands and the neighbouring continent; very common in all the salt marshes on the south side of Jamaica. Linnæus doubts whether it be distinct from the *bucephalon* of Plumier. Martyn's Miller's Dict.

BATIS, in *Entomology*, a species of *PHALÆNA*, found in England and some other parts of Europe. The anterior wings are brown, with five rose-coloured spots on each; posterior ones whitish. This is a rare and elegant insect, and is called by collectors of English insects the peach-blossom moth. Linn. Donov. Brit. Inf. &c.

BATIS, in *Ichthyology*, a species of *RAJA*, called in England the *SKATE*. It is varied; back smooth in the middle, with a single row of spines on the tail. Linnæus.

This is the largest fish of the Ray tribe; it inhabits all the northern parts of Europe in immense quantities, though it is certainly less common than the thornback, with which it is sometimes confounded. The usual size is from two to three feet in length, or rather more, including the tail; and they have been taken of the weight of an hundred and fifty

or two hundred pounds. They couple in March and April, and spawn in May. The flesh of the skate is thought better than that of the other Rays.

BATISTANI, in *Ancient Geography*, a people of Spain, who inhabited the northern part of Bætica.

BATISTE, in *Commerce*, a fine white kind of linen cloth, manufactured in Flanders and Picardy.

There are three kinds of batiste: the first very thin; the second less thin; and the third much thicker, called Holland batiste, as coming very near the goodness of Hollands. The chief use of batiste is for neck-cloths, head-cloths, surplices, &c.

BATMAN, a weight in Turkey, consisting of six okes. Forty of these batmans make a camel's load, and amount to about seven hundred and twenty pounds English weight.

Batman, or battarant, is a weight used in Turkey and Persia. The Turkish batman is of two kinds; the larger containing six okes, or *ocquos*, at three pounds three quarters Paris weight the *ocquo*; so that the batman amounts to about twenty-two Paris pounds and an half; the smaller, composed likewise of six *ocquos*, at fifteen ounces the *ocquo*, amounting to five pounds ten ounces. The Persian batman is likewise of two kinds: one called the *king's weight*, *batman de chahi*, or *chray*, used for weighing most of the necessaries of life, equivalent to about twelve pounds and an half Paris weight; the other called *batman of Touris*, equal to six pounds four ounces Paris or Amsterdam weight. These, at least, are the proportions given by Tavernier. Chardin rates the Persian batmans somewhat lower, viz. the former at twelve pounds twelve ounces; and the latter at five pounds fourteen ounces.

BATMANSON, JOHN, in *Biography*, prior of the Carthusian monastery, or Charter-house, in London, in the 16th century. He studied at Oxford; and being a great favourite of Edward Lee, archbishop of York, wrote at his request against Erasmus and Luther. He died in 1531, and was buried in the Charter-house. Bale represents him as proud, arrogant, and fond of wrangling; and says, that Erasmus styles him an ignorant fellow, and vain-glorious even to madness. Pits, on the other hand, commends his genius, learning, piety, and zeal; his acquaintance with the scriptures, and his highly exemplary life. His works are "Animadversiones in Annotationes Erasmi in N. T." "A Treatise against some of Luther's writings;" both these he afterwards retracted: "Comment. in Proverb. Solomonis;"—"in Cantica Canticorum;" "De Unica Magdalenâ;" "Institutiones Noviciorum;" "De Contemptu Mundi;" "De Christo duodenni," a homily on Luke ii. 42; and "On the words *Misus est*, &c." *Biog. Brit. Gen. Dict.*

BATNÆ, in *Ancient Geography*, a town of Mesopotamia, in Odroene. Ammianus Marcellinus calls it Batne and Batna, and says, that it was a municipal city of Anthemusia, of great trade, built by the Macedonians, at a small distance from the Euphrates. The emperor Justinian made it a place of defence by encompassing it with walls. Procopius calls it a small and obscure town, and says, that it was about a day's journey distant from Edeffa. It lay south of Edeffa, and east of Zeugma. It was reduced by Trajan, who took it from Chosroes, king of the Parthians.

BATRÆA was also a small town of Syria, situate between Berea and Hierapolis, pleasantly seated in a grove of cypresses, about twenty miles from the latter city. When Julian visited this town, A. D. 363, the solemn rites of sacrifice were decently prepared by the inhabitants, who seemed attached to the worship of their tutelary deities, Apollo and Jupiter.

BATNIR, or BATINDA, in *Geography*, a town of Hindostan, in the country of Moultan, in a district famous for pastures and fine horses. Timur marched from Adjodin, a town included in one of the large islands formed by the branches of the Setlege, to Batnir, the distance of 60 *colles*, 50 *colles* being equal to about 95 British miles; and in his way he crossed an exte five desert; so that Alexander was not misinformed when he was told there was a desert beyond the Hyphasis. After taking and destroying Batnir, represented as a very strong place, which, however, employed only a few days, he marched by a circuitous road to Samanah, directly distant from Batnir only 72 geographical miles. Batnir is about 150 miles, E. S. E. of Moultan, and 170 N. W. of Agimere. N. lat. 29° 15'. E. long. 74° 40'.

BATO, one of the Ladrone islands. N. lat. 12°. E. long. 142°. See BAN.

BATO, a river of Italy, in the kingdom of Naples, which runs into the Mediterranean, 2 miles S. E. of Scalea, in the province of Calabria Citerà.

BATOA, a small island near the west coast of Sumatra, seated very nearly under the equinoctial line. E. long. 98°.

BATOE, *Ikan Batoe*, *Iang Aloe*, & *Ikan Pampus Cambodia*, names given by Valent. in his work on Indian fishes, to the species of *CHÆTODON*, specifically called *ANNULARIS* by Gmelin.

BATON, or BATOON, in *Heraldry*. See BASTON.

BATON, or *Boston*, as an instrument of punishment. See BASTONADO.

BATON, Fr. in *Music*, a musical character for silence, during two bars in *alla breve* time, and four of common and triple time. It fills up two spaces of the five-line staff;

and has a 2 or a 4 placed over it, proportioned to the time of the movement. See BREVE, TIME-TABLE, and RESTS.

BATOONS or ST. PAUL, *Bastoncini di San Paolo*, in *Natural History*, a name given by some of the Italian writers, as Augustino Scilla and others, to the *lapides Judaici*, or other species of *ebeni*. These are found in vast abundance in the island of Malta; and as every thing there is commemorated with some title, with St. Paul at the end of it, these are called *baculi Sti Pauli*, or *St. Paul's batoons*.

BATOPILAH, in *Geography*, a town of North America, in the province of New Navarre, 120 miles north of Cinaloa.

BATOS, in *Ichthyology*. See BATIS.

BATRACHA, in *Ancient Geography*, a town of Asia, in Sarmatia. Ptolemy.

BATRACHIUS *Lapis*, the *frog stone*, a name applied by different writers to two very different substances; some understanding by it lumps of common flint, which have accidentally formed themselves into this figure; and others, those pieces of amber, which contain either a whole frog, or any part of one.

BATRACHITES, among *Ancient Naturalists*, a kind of gem found in Egypt, denominated from its resemblance in colour to a frog. The word is formed from *βατραχος*, *rana*, a frog. Pliny speaks of three stones under this denomination; *unam ranae similem colore*, *alteram eburi* (or rather, according to Hardouin's correction, *ebeni*), *tertiam rubentis et nigro*. The batrachites differed from the modern *hyacinthes*, which does not appear to have been known to the ancients.

BATRACHOIDE, in *Ichthyology*, a genus of fishes of the JUGULARES kind, established by Lacépède for two fishes; the one belonging to the *Gadus*, and the other to

the

the *Blennius*, genera of Linnæus, viz. *G. tau*, and *B. rarinus*. The character of the batrachoides consists in having the head very large and greatly depressed; opening of the mouth very spacious; and one or more beards situated about or at the under side of the lower jaw.

BATRACHOMYOMACHIA, formed of the Greek *βελραχος*, frog, *μυς*, mouse, and *μαχη*, pugna, and denoting the battle of the frogs and the mice; the title of a burlesque poem, usually ascribed to Homer. The subject of the poem is the death of Pŷcharpax, a mouse, son of Toxartes, who being mounted on the back of Phisŷmathus, a frog, on a voyage to its palace, to which he had been invited, was seized with fear when he saw himself in the middle of the pond, so that he tumbled off and was drowned. Phisŷmathus being suspected to have shaken him off with design, the mice demanded satisfaction, and unanimously declared war against the frogs. Stephens, Numbesius, and other modern authors, take the poem not to be Homer's; but several of the ancients seem of another opinion; and Statius, who wrote under Domitian, makes no doubt of it. See Fabric. Bibl. Græc. lib. ii. c. 1. § 3.

BATRACHOSALIS, in *Ichthyology*, a name assigned by many of the Greek writers to the fish called by Linnæus *LOPHIUS PISCATORIUS*.

BATRACHUS, the name given by Klein to the Linnæan *LOPHIUS PISCATORIUS*.—*Batrachus capite, ricuque raris*, &c. Klein. The last writer also describes the Linnæan *LOPHIUS VESPERTILIO*, as *BATRACHUS capite vomeris instar cornuto*, &c.

BATRACHUS, a species of *SILURUS*, found in Asia and Africa. The dorsal fin is single, and contains sixty rays; beards of the mouth eight. Linn. Mus. Fr.—The tail is entire.

BATTA, or **BATA**, in *Geography*, a duchy or province of Africa, situate on the south-west of Pango, and having Dembo, Amulassa, and the salt-petre mountain on the east, on the south the marquisate of Incussa, and the burnt mountains, and Congo and Pemba on the west. It is of considerable extent, was formerly called Anguirima or Aghirimha, and was a kingdom of itself, till both king and people submitted to the kings of Congo. This country is generally fertile, well watered by rivers, and produces several sorts of grain. The inhabitants are more civilized than their neighbours.

BATTA, the capital of the above duchy, is distinguished in no other respect besides the fertility of its territory, and its being the residence of the governors of this province. These are allowed to have a number of arquebusers in pay, to defend it from the incursions of the wild Giagas, or Jagas, who inhabit the districts near its eastern frontiers, beyond the mountains of the Sun and Saltpetre, and who chiefly subsist by ravaging the adjacent territories. The road between this capital and that of the kingdom of Congo, called St. Salvador, has, it is said, a great number of houses and hamlets on both sides.

BATTA, the name of a country in Sumatra, where the English have two settlements. The inhabitants still eat human flesh, but restrict themselves to that of prisoners taken in war, and capital offenders.

BATTFLE GROUND, denotes land lying between England and Scotland, of which the right of possession was disputed, when they were two distinct kingdoms.

The word imports as much as litigious, or disputable ground, from *battere*, to beat or fight.

BATTACKS, or **BATTOGES**, a punishment in Russia, similar to the bastinado, or bastonado, of China, Turkey, &c. The delinquent is stripped naked, and made to lie on

his belly, while two executioners beat him with small sticks, till the judge cries out, *enough*. The order to desist is frequently not given till the back of the unfortunate sufferer has been mortally mangled. During the whipping, he is obliged to pronounce the word "Winawat," which means "I am guilty;" and at the end of the punishment he must go and kiss the feet of him who directed it, and thank him that he did not make it more severe. The highest lords are not exempted from the battoges, and take vengeance for it on their unhappy vassals. This punishment is particularly reserved for the inferior orders, whom malversation or roguery would any where else drive from their employments. In Russia, it is reckoned sufficient to reduce them to an inferior employment, after the correction of the battoges. Chantreau's Travels in Russia, vol. i. p. 117. See **BASTONADO**.

BATTAGLIA, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Capitanata, 3 miles N. W. of Vielle.

BATTAL, in *Ancient Geography*, a promontory of Arabia, north-east of Julia Cæsarea.

BATTALIA, an army ranged in order of battle, or ready for engagement.

In this sense, we meet with the depth of a battalia; to march in battalia, with the baggage in the middle; to break the battalia, &c. In the Roman battalia, the *HASTATI* made the front.

BATTALION, in the *Military Art*, signifies a small body of infantry, arranged in regular order, and instructed to march and to act in concert.

There are different opinions respecting the force of which a battalion should consist. If composed of too great a number of men, it cannot perform its evolutions with the necessary facility; if, on the contrary, the troops are not sufficiently numerous, it is incapable of producing by its attack any considerable effect. The number must therefore be so regulated, as to permit the necessary manœuvres to be executed with promptitude and regularity; and at the same time to compose a solid body, capable both of charging with firmness, and of sustaining the assault of other corps to which it may be opposed without falling into disorder.

The number of the battalion varies according to the usages of belligerent nations, their arms, the manner in which they employ those arms, and the order in which they engage. Europeans formerly differed very widely on all these points; but at present all the continental powers, the Turks alone excepted, observe nearly the same dispositions with respect to the battalion. The term even is adopted in every modern language.

The French have fixed the number of the battalion at about 700 men. Some nations form them still stronger, others weaker. In the English service they usually consist, in time of war, of ten companies; forming, exclusively of the staff, a total of between seven and eight hundred. When employed on service, the battalions being filled up at the commencement of a campaign, and rarely recruited till its close, are seldom or ever complete; as well from the loss they sustain in different engagements, as on account of sickness and other accidents inseparable from the military profession.

The arms of the battalion have been frequently and materially altered. In the infancy of modern tactics, one third of the troops were furnished with pikes, and drawn up in the centre; the other two thirds carrying muskets, were poited on the wings, to flank, protect, and second, by their fire, the onset of the pikes. The infantry are now universally armed with firelocks and bayonets, the use of the pike being completely laid aside.

The modern method of arrangement has been decried by the

the ingenious chevalier de Folard (*Traité de la Colonne*, p. 7.) as rendering the battalions too shallow, weak, incapable of supporting each other, and exposing them to be easily penetrated and broken through, all which he denominates essential faults in tactics. According to him, the real strength of a corps consists in its thickness, or the depth of its files, and their connection and closeness, this rendering the flanks almost as strong as the front. He even lays it down as a maxim, that every battalion arranged deeply, and with a small front, will defeat another much stronger than itself disposed according to the usual method. In fact, a corps whose front is widely extended, and whose depth is but small, manœuvres with more difficulty, and cannot totally avoid that wavering from which the close order of M. Folard's battalion or column renders it comparatively exempt. The opinion of the Chevalier has been in a great measure adopted by his countrymen, though his theory has been violently attacked by two French officers formerly in the service of the States General. They admit the superior strength of the column to the modern battalion, were the action to be decided with pikes and swords; but maintain that where fire-arms are used, M. Folard's column is but ill calculated for the purpose, and must be infallibly destroyed. The late campaigns in Italy furnish the best commentary upon these separate systems.

BATTALION, Square, is a battalion the files of which are equal to the ranks, and whose sides form an equal front. There are two kinds, the solid, and the hollow: in the former, the ordinary intervals between the ranks and files are the only ones preserved; in the latter, a vacant space is left in the centre, of pretty considerable extent, according to the ground occupied by the battalion. We shall presently give some account of the evolutions necessary in forming both kinds of the square.

The *solid* square, however ingenious in its formation, and respectable in its appearance on a field of exercise, is of very little utility in actual service. In the first place, it suffers prodigiously from the fire of the enemy, especially if artillery is brought to bear upon it; in the second, it is next to impossible for the troops in the centre of the battalion to employ their own fire effectually. M. de Folard, in his treatise de la Colonne, exposes much at large the defects both of the solid and the hollow square. He indirectly, however, recommends their use; his own column being nothing more than two or three battalions drawn up according to the rules of the solid square, and placed without any intervals in the rear of each other. Regarding, however, the solid square as entirely distinct from the column, of which we shall speak more at large in its proper place, we shall here conclude by observing that the only case in which it seems capable of affording any real service is when opposed to an enemy whose forces consist entirely of cavalry.

The *hollow* square, which claims for its inventor the celebrated prince Maurice of Nassau, is much less unwieldy in its movements, sooner formed, and more easily reduced, than the solid. Its fire too is more regular, better directed, and does much greater execution. It however participates in a great measure of all the disadvantages of the solid square, and its use can only be recommended in cases of the last extremity, or, as above, when opposed to cavalry.

BATTALION, Triangular, is a body of troops disposed in a triangle, whose ranks, augmenting equally, form an arithmetical progression. Many skilful officers have preferred it to the square, from its presenting a greater front, and being able to make head on all sides. The difficulty is to enure soldiers to march in this order; and we may conclude the triangular only preferable to the square battalion in close ac-

tion, when it is necessary to preserve an extended front or when the nature of the ground requires such a disposition.

BATTALION, Round, is that in which the ranks form a number of concentric circles. The Romans made frequent use of this manœuvre in cases of emergency, and were very perfect in its execution. Cæsar's commentaries furnish several examples, especially on occasion of the defeat of Sabinus and Cotta by Ambiorix, where the formation and nature of the orb are very satisfactorily elucidated. (*De Bell. Gall. lib. v.*) But in the battle between Cæsar and Labienus in Africa, translators seem to have mistaken for the orb, a disposition perfectly different. (*Hist. de Belio Afr.*)

Although recommended by M. de Puysegur, the round as well as the triangular battalion are now generally disused.

At a crisis like the present, we trust the following account of the training the recruit for service, the order and formation of the battalion, and the principal evolutions it is destined to execute, will not prove wholly unacceptable to our readers. Care has been taken to render the narration as little tedious as possible, and as concise as may be consistent with perfectivity.

Drill of the Recruit without Arms.

It requires in the instructors to whom this duty is entrusted, and who are answerable for its execution, an unremitting perseverance, an accurate knowledge of the subject, and a clear and concise method of conveying instruction, united with a firmness capable of commanding perfect attention to their directions. They must allow for weakness of capacity in the recruit, be patient and not rigorous where endeavour and good-will are not wanting, as quickness is only to be acquired by much practice. Officers and instructors must be critically exact in their own commands, as well as in observing the execution of what they require from others. Without this, all labour will prove ineffectual, and the proposed discipline never be attained.

The recruit must be taught progressively to comprehend one thing before he proceeds to another. In the first circumstances of position, his firelock, fingers, elbows, &c. are to be justly disposed by the instructor. When more advanced, recruits should not be touched, but from example and directions be taught to correct themselves when admonished. They should not be kept too long at any particular part of their exercise, so as to fatigue or render them uneasy; and marching without arms ought to be much intermixed with the use of the fire-lock. Fife, or music, must on no account be used. The young soldier is to be confirmed by habit alone in that cadence of step he is afterwards to maintain in marching to the enemy in spite of every variety of noise or circumstance that may tend to derange him.

Each recruit must be trained singly, and in squad, as hereafter described; nor until steadied in various points of his duty, is he to be allowed to join the battalion, which is sensibly inconvenienced by the awkward behaviour even of one man. On return from long absence, every soldier must be re-drilled before he can again join his company.

I. Position of the Soldier. The equal squareness of the shoulders and body to the front is the first and great principle of the position of a soldier. The heels must be in a line, and closed; knees straight, without stiffness; toes a little turned out, so that the feet may form an angle of about sixty degrees; the arms are to hang near the body, but not stiff, the flat part of the hand and little finger touching the thigh; the thumbs as far back as the seams of the breeches; elbows and shoulders to be kept back; the belly rather drawn in, and the breast advanced, but without constraint; the body upright, but inclining forward,

ward, so that its weight principally bears on the fore part of the feet; the head to be erect, and turned neither to the right nor left. The position in which a soldier should move, determines that which he is to observe when standing still. No method must be left untried to supple the limbs, and banish the air of the rustic. But that excess of position which stiffens the person, and tends to throw the body backward instead of forward, is contrary to every true principle of movement, and must therefore be most carefully avoided.

II. *Standing at Ease.* 1. On the word *Stand at Ease*, the right foot must be drawn back about six inches, and the greatest part of the weight of the body be brought to bear on it; the left knee a little bent, the hands brought together before the body; but the shoulders to be kept back and square; the head to the front, and the whole attitude without constraint. 2. On the word *Attention*, the hands are to fall smartly down the outside of the thighs; the right heel to be brought up on a line with the left, and the proper position of a soldier to be immediately resumed. After standing at ease for any considerable time in cold weather, the men may be permitted, by command, to move their limbs, but without quitting their ground, so that on the word *Attention*, no one shall have materially lost his dressing in the line.

III. *Eyes to the right, &c.* On the word *Eyes right*, glance the eyes to the right, with the slightest possible turn of the head; *Eyes left*, turn them in the like manner to the left; *Eyes front*; the look and head are to be directly to the front, the habitual position of the soldier. These motions are only useful on the wheeling of divisions, or when dressing is ordered after a halt. Particular attention must be paid, in the several turnings of the eyes, to prevent the recruit from moving his body, which should be preserved perfectly square to the front.

IV. *The Facings.* In going through the facings, the left heel never quits the ground; the body must rather incline forward, and the knees be kept straight. At the word, *to the right, face*, first, place the hollow of the right foot smartly against the left heel, keeping the shoulder square to the front; second, raise the toes, and turn to the right on both heels. *To the left, face*; first, place the right heel against the hollow of the left foot, shoulders square to the front; second, turn, as before, to the left on both heels. *To the right about, face*; first, place the ball of the right toe against the left heel, shoulders square to the front; second, raise the toes, and turn to the right about on both heels; third, bring the right foot smartly back, in a line with the left. *To the left about, face*; first, place the right heel against the ball of the left foot, keeping the shoulders square to the front; second, turn, as before, to the left about; third, bring the right foot smartly up, in a line with the left. The utmost precision must be observed in the facings, for if they are not exactly executed, a corps, although previously properly dressed, will lose their dressing on every small movement of facing.

V. *Position in Marching.*—*March!* The soldier must here, as much as possible, maintain the position of his body, as directed in sect. i. He must be well balanced on his limbs. His arms and hands, without stiffness, must be kept steady to his sides, and not suffered to vibrate. He must not stoop forward, still less lean back. His body is to be kept square to the front, and thrown rather more forward in marching than when halted, that it may accompany the movement of the leg and thigh, which movement must spring from the haunch. The ham must be stretched, but without stiffening the knee. The toe a little pointed, and kept so near the

ground, that the shoe-soles may not be visible to a person in front. The head to be well kept up, straight to the front, and the eyes not suffered to be cast down. The feet, without being drawn back, must be placed flat on the ground.

VI. *Ordinary Step.* The length of each pace, from heel to heel, is 30 inches, and the recruit must be taught to take 75 of these steps in a minute, without tottering, and with perfect steadiness. Ordinary time being the pace on all occasions whatever, unless greater celerity be particularly ordered, the recruit is to be carefully and thoroughly trained to this most essential part of his duty, and made perfectly to understand, that he is to maintain it for a long time together, in line, in column, and in marching over rough or smooth ground. This is the slowest step which a recruit is taught, and is also applied in all movements of parade.

VII. *The Halt.* On the word, *halt*, let the rear foot be brought upon a line with the advanced one, so as to finish the step which was taking when the command was given.

VIII. *The oblique Step.* Having acquired the regular length and cadence of the ordinary pace, the recruit is next to be taught the oblique step. At the words, *to the left oblique—march!* he will, without altering his squareness of personal position, when he is to step with his left foot, point, and carry it forward 19 inches, in the diagonal line, to the left, which gives about 13 inches to the side, and nearly the same number to the front. On the word *two*, he will bring forward his right foot 30 inches, thus placing the heel of that foot 13 inches directly before the left one. Here he will pause, and on the word *two*, continue the same mode of marching, by advancing his left foot 30 inches, pausing at each step, until confirmed in his position, as it is essentially necessary to take the greatest care in preserving the shoulders square to the front. Combining these two movements, the obliquity gained will amount to an angle of about 25 degrees. When the recruit is habituated to the step, he must be made to continue it firmly, without pausing, and in the cadence of the ordinary pace, viz. 75 steps in the minute. As all marching (the side step excepted) commences by the left foot, whether the obliquing commences from the halt, or on the march, the first diagonal step taken, is by the leading foot of the side inclined to, when it comes to its turn, after the command is pronounced. Squareness of person, and the habitual cadenced step are, consequently, the great directions of the oblique, as well as the direct march.

Each recruit should be separately and carefully instructed in the principles of the foregoing eight sections of the drill. They form the basis of all military movements. Three or four recruits will now be formed in one rank, at very open files, and instructed in the following manner.

IX. *Dressing when halted.* Dressing is taught equally by the left as by the right. On the word, *dress*, each individual will cast his eyes to the point to which he is ordered to dress, with the smallest turn possible of the head, but preserving the shoulders and body square to the front. The whole person of the man must move as may be necessary, and bending backward and forward is not to be permitted. He must take short, quick steps, thereby gradually and exactly to gain his position, and on no account be permitted to attempt it by any sudden or violent alteration, which will infallibly derange whatever is beyond him. The faces of the men, not their breasts, or feet, are the line of dressing. Each soldier is to be able just to distinguish the lower part of the face of the second man beyond him. In dressing, eyes are always turned to the officer who gives the word; who is posted at the point by which the body halts: and who from that point corrects his men on another, at or beyond the

the opposite flank. Faults to be avoided, and generally committed in dressing, are, passing the line; the head forward, and body kept back; shoulders not square; or the head turned too much.

Two or more men being moved forward, or backward, a given number of paces, and placed in the new line and direction, the following commands will be given: 1. *by the right (or left) forward-dress*; 2. *on the right (or left) backward-dress*. The dressing once accomplished, *eyes front* will be given, that heads may be replaced, and remain square to the front. No rank, or body, ever should be dressed, without the officer on its flank determining a line on which to form it, and for that purpose taking as his object the distant flank man, or a point beyond him, or a man purposely thrown out. Dressing must then be made gradually, and progressively, from the fixed point, towards the distant flank one; and each man successively, but quickly, must be brought up into the true line, so as to become a new point, from whence the instructor proceeds in the correction of the others; and himself, while thus occupied, must take care, that his person, at least his eyes, be in the true line, which he is then giving.

X. *Stepping out*. The squad marches, as already directed, in ordinary time. On the word, *step out*, the recruit must be taught to lengthen his step to 33 inches, by leaning forward a little, but without altering the cadence. This step is necessary, when a temporary exertion in line, and to the front, is required; or when the rear divisions of a column are to move up in line with the leading ones, and is applied both to ordinary and quick time.

XI. *Mark time*. On this word, the foot then advancing completes its pace. The cadence is then continued, without gaining any ground, but alternately throwing out the foot, and bringing it back square with the other. At the word, *ordinary time*, or *forward*, the usual pace of 30 inches will be taken. This step is necessary marching in line, when any particular battalion is advanced, and has to wait for the coming up of others.

XII. *Stepping short*. On the word, *step short*, the foot advancing will finish its pace, and afterwards each recruit will step as far as the ball of his toe, and no farther, until the word, *forward*, be given, when the usual pace is to be taken. This step is useful when a momentary retardment either of a battalion in line, or of a division in column, is required.

XIII. *Charging the Feet*. To perform this in marching, the advancing foot completes its pace, and the ball of the other is brought up quickly to the heel of the advanced one, which instantly makes another step forward, so that the cadence may not be lost. This is required of an individual who may be stepping with a different foot from the rest of his division; in doing which, he will, in fact, take two successive steps with the same foot.

XIV. *Side, or closing Step*. This is performed from the halt in ordinary time, at the following command: *Close to your right, or left (a caution)—March!* On the latter word, eyes are turned to the right, and each man carries his right foot about 12 inches directly to his right; or, if the files are closed, to his neighbour's left foot, and instantly brings up his left foot, till the heel touches his right heel; he then pauses, so as to perform this movement in ordinary time, and proceeds to take the next step in the same manner: the whole with perfect precision of time, shoulders kept square, knees not bent, and in the true line on which the body is formed. At the word *halt*, the whole halt, turn their eyes to the front, and are perfectly steady.

XV. *Back Step*. This is performed in the ordinary time and length of pace, from the halt, on the command *step back*

—*March!* The recruit must be taught to move straight to the rear, preserving his shoulders square to the front, and his body erect. On the word *halt*, the foot in front must be brought back square with the other. A few paces only of the back step can be necessary at a time.

XVI. *Quick Step*. The cadence of the ordinary step having become perfectly habitual to the recruits, they are now to be taught to march the quick time, which is 108 steps in the minute, each of 30 inches, making 270 feet in a minute. The word of command, *Quick—March!* is given with a pause between them. The word *Quick*, is to be considered as a caution, and the whole to remain perfectly still and steady. On the word *March!* the recruits step off with the left foot, keeping the body in the same posture, and the shoulders square to the front. The foot to be lifted from the ground, that it may clear any stones, or other impediments in the way, and to be thrown forward, and placed firm. The whole of the sole to touch the ground, and not the heel alone. The knees are not to be bent, neither are they to be stiffened, so as to occasion fatigue or constraint. The arms to hang with ease along the outside of the thigh; a small motion to prevent restraint may be permitted, but not to swing out, and thereby occasion the least turn, or movement of the shoulder. The head is to be kept to the front; the body well up, and the utmost steadiness to be preserved. This is the pace to be used in all filings of divisions from line into column, or from column into line; and by battalion columns of manœuvre, when independently changing position. It may occasionally be used in the column of march of small bodies, when the route is smooth, and no obstacles occur; but in the march in line of a considerable body it cannot prudently be required, nor often in a column of manœuvres. Fatigue will otherwise arise to the soldier, and more time be lost in hurry and inaccuracy than is attempted to be gained by quickness.

N. B. The word *March* given singly, at all times denotes that *ordinary time* is to be observed. When the *quick march* is meant, that word will precede the other. The word *March* marks the commencement of movements from the halt; but is not given when the corps is in previous motion.

XVII. *Quickest Step*. The quickest time, or wheeling march, is 120 steps of 30 inches each, or 300 feet, in the minute. The directions already given for the march in quick time are equally applicable to the march in quickest time. This is adapted chiefly to the purpose of wheeling, and is the rate at which all bodies accomplish their wheels; the outward file stepping 33 inches, whether the movement is from line into column, into column during the march, or from column into line. In this time also divisions should double and move up, when passing obstacles in line, or when in column of march it becomes necessary to increase or diminish the front.

Three or four recruits in rank, with intervals of twelve inches between them, should be practised in the various steps, that they may acquire a firmness and independence of movement. Many different times of march would only perplex the soldier: the three already mentioned must suffice. Plummets, which vibrate the required times of march in a minute, are of great utility, and can alone prevent or correct uncertainty of movement. They must be in the possession of, and occasionally referred to, by each instructor of a squad. The several lengths of plummets swinging the times of the different marches in a minute, are as follows:

Ordinary time,	75 steps in a minute,	24 inch.	96 hand.
Quick do.	108 do.	- 12	3
Quickest do.	120 do.	- 9	80
			A market

A musket ball, suspended by a string which is not subject to stretch, and on which are marked the different required lengths, will answer the above purpose, and should be frequently compared with an accurate standard. Accurate distances of steps may also be marked out on the ground along which the soldier is practised to march, and thereby accustom him to the just length of each.

Six or eight recruits will now be formed in a rank, at close files, having a steady well-drilled soldier on their flank to lead; and *file marching* may be taught them.

XVIII. *File Marching.* The recruits must first face, and then be instructed to cover each other exactly in file, so that the head of the man immediately before may conceal the heads of all the others in his front. The strictest observance of all the rules for marching is particularly necessary in marching by files, which is first to be taught at the ordinary, and afterwards in quick time. On the word *March*, the whole immediately step off together, gaining at the very first step thirty inches, and continuing each step without increasing the distance betwixt each recruit, every man locking or placing his advanced foot on the ground, before the spot whence the preceding man has taken up his. No looking down nor leaning backward is to be tolerated on any pretence. The leader is to be directed to march straight forward to some distant object given him for that purpose, and the recruits made to cover one another during the march with the most scrupulous exactness. Great attention must be paid to prevent them from marching with their knees bent, which they will at first be extremely apt to do, from an apprehension of treading down the heels of those before them.

XIX. *Wheeling in single Rank, from the Halt.* At the word to the *Right Wheel*, the man on the right of the rank faces to that flank; on the word *March*, they step off together, the whole turning their eyes to the left (the wheeling flank), except the left hand man, who looks inwards, and during the wheel becomes a kind of base line for the rest to conform to and maintain the uniformity of front. The outward wheeling man always lengthens his step to thirty-three inches. The whole observe the same time; but each man shortens his step, in proportion as he is nearer to the standing flank on which the wheel is made. During the wheel, the whole remain closed to the standing flank, i. e. they touch without incommoding their neighbour; nor must they stoop forward, but remain upright. Opening out from the standing flank, or closing in upon it, during the wheel, are equally to be avoided. On the word *Halt—Dress*, each man halts immediately, without jumping forward or making any false movements. When able to perform the wheel with accuracy in the ordinary time, the recruits must be next practised in the quickest. Nothing sooner tends to enable them to acquire the proper length of step, according to their distance from the pivot, than continuing the wheel without halting for several revolutions of the circle.

XX. *Wheeling, in single Rank, from the March.* The recruits are first taught to perform this wheeling at the ordinary, afterwards in the quickest time, the proper wheeling step. The rank marching to the front in ordinary time, receives the word of command, *Right—Wheel*. The man on the right of the rank instantly halts, and faces to his right. The rest of the rank turning their eyes to the wheeling flank (as above directed), immediately change the step together to wheeling time. As soon as the portion of the circle intended to be wheeled, is completed, the words *Halt—Dress* will be given, (a pause of two or three seconds may be made), and then *March*, at which the whole rank steps off together in ordinary time.

VOL. III.

XXI. *Wheeling backwards, in single Rank.* At the word *On your Right, backwards—Wheel*, the right-hand man of the rank faces to his left. At the word *March*, the whole step backward in wheeling time, dressing by the outward wheeling man; those nearest the pivot making their steps extremely small, and those towards the wheeling man increasing them as they are placed nearer to him. The recruit in this wheel must not bend forward, nor be suffered to look down; but by calling his eyes to the wheeling flank, preserve the dressing of the rank. On the word *Halt*, the whole remain perfectly steady, still looking to the wheeling flank, till they receive the word *Right—Dress*. The recruits should be first practised to wheel backwards at the ordinary step. At all times it will be necessary to prevent their hurrying the pace, an error soldiers are very subject to, particularly in the backward wheel. Where large bodies wheel from line into column, this wheeling is necessary to preserve the covering of pivot flanks, and the distances of the divisions, which the line has broken into.

XXII. *Wheeling in single Rank, on a moveable Pivot.* In performing this wheel, both flanks are moveable, and describe concentric circles round a point, which is removed a few paces from what would otherwise be the standing flank; and eyes are all turned towards the directing pivot man, whether he is on the outward flank or the flank wheeled to. When the wheel is to be made to the directing pivot flank (suppose the left), the rank marching at the ordinary pace, receives the word *Right Shoulders Forward*; on which the pivot man, without altering either the time or length of his pace, continues his march on the circumference of the lesser circle; and tracing out a considerable arch, on the principle of dressing, gradually brings round his rank to the direction required, without obliging the other flank, which is describing the circumference of a larger circle, to too great hurry. On the word *Forward*, shoulders are squared, and the pivot marches directly to his front. When the directing pivot is on the outward flank, and has to describe the circumference of the larger circle, on the word *Left Shoulders Forward*, he will (preserving the time and length of his pace) gradually bring round the rank to the required direction, so as to enable the inward flank to describe a similar arc of a lesser circle, concentric to the one he himself is moving on. During both these wheels, the rank dresses to the proper pivot; and when he describes the smaller circle of the wheel, the other flank which has more ground to go over, will quicken its march and step out. When the pivot describes the greater circle of the wheel, the other flank having less ground to go over, will step shorter and gradually conform. In the first case, the recruit must be cautioned against opening out from the pivot; and in the latter, from crowding on him. The just performance of this mode of wheeling depends so much on the directing pivot, that a well-drilled soldier should at first be placed on the flank named, as the proper pivot, and changed occasionally. It is used when a column of march (to follow the windings of its route) changes its direction in general less than the quarter circle.

Drill of the Recruit with Arms.

I. *Position of the Soldier.* When the firelock is given, and is shouldered, the person of the soldier remains in the position described in section I. of the drill without arms, except that the wrist of the left hand is turned out, the better to embrace the butt; the thumb alone is to appear in front, the four fingers to be under the butt, and the left elbow a little bent inwards, without being separated from the body, or being more backward or forward than the right one. The firelock is placed in the hand, not on the middle

of the fingers, and so carried, that it shall not raise, advance, or keep back, one shoulder more than the other. The butt must therefore be forward, and as low as can be permitted without restraint; the fore-part nearly even with that of the thigh, and the hind-part of it pressed by the wrist against the thigh. The piece must be kept steady and firm before the hollow of the shoulder. Should the firelock be drawn back, or attempted to be carried high, in that case one shoulder will be advanced, the other kept back, and the upper part of the body distorted, and not placed square with respect to the limbs. Each recruit must be separately taught the position of shouldered arms, and not allowed to proceed until he has acquired it.

II. *Motions of the Firelock.* The following motions of the firelock will be taught and practised, until each recruit is perfect in them; being necessary for the ease of the soldier in the course of exercise. 1. Supporting arms; 2. Carrying arms; 3. Ordering at ease arms; 4. Standing at ease; 5. Attention; 6. Shouldering; 7. Trailing arms; 8. Shouldering from the trail. The recruit must be accustomed to carry his arms for a considerable time together: it is most essential he should do so, and not be allowed to support them so often as is practised; under the idea that long carrying them is a position of too much restraint.

III. *Forming the Squad.* When the squad, or division, of six or eight files, is ordered to *Fall in*, each man, with carried arms, will, as quick as possible, take his place in the ranks, beginning from the flank to which he is ordered to form. He will dress himself in line by the rule already given, assume the ordered position of a soldier, and stand perfectly still and steady, until ordered to stand at ease, or that some other command be given him. Attention must be paid, that the files are correctly close; that the men in the rear ranks cover well, looking their file leaders in the middle of the neck; that the ranks have their proper distance of one pace, or 30 inches, from each other; that all the ranks are equally well dressed; that the men do not turn their heads to the right or left; and that each man has the proper unconstrained attitude of a soldier.

IV. *Open Order.* The recruits being formed in three ranks at close order, on the caution *Rear ranks take open order*, the flank men, on the right and left of the centre and rear ranks, step briskly back, one and two paces respectively, face to the right, and stand covered, to mark the ground on which each rank is to halt, and dress at open order: every other individual remains ready to move. On the word *March*, the dressers front, and the centre and rear ranks fall back one and two paces, each dressing by the right, the instant it takes its ground.

V. *Close Order.* On the word *Rear ranks take close order*, the whole remain perfectly steady. At the word *March*, the ranks close within one pace, marching one and two paces, and then halting.

VI. *The Manual Exercise.* The following is the regulation for performing the manual exercise, the recruit standing at the position already described, with his firelock shouldered. The manual is not to be executed by one word, or signal, but each separate word of command is to be loudly and distinctly given by the officer who commands the body performing it. Three seconds are the time allotted between each motion, except that of fixed bayonets, in which a longer time must be given.

Order Arms. Bring the firelock to the trail in two motions; seizing it at the first at the lower loop, just above the swell; at the second, bring it down to the right side, the butt within two inches of the ground; at the third, drop the butt on the ground, placing the muzzle against the

hollow of the right shoulder, and the hand flat upon the sling.

Fix Bayonets. At the word, *fix*, place the thumb of the right hand, as quick as possible, behind the barrel, taking a gripe of the firelock. As soon as the word of command is fully out, push the firelock a little forward, at the same time drawing out the bayonet with the left hand, and fixing it with the utmost celerity. The instant this is done, return as quick as possible to the order as above described, and stand perfectly steady.

Shoulder Arms. As soon as the word *shoulder* is given, take a gripe of the firelock with the right hand, as in fixing bayonets; and at the last word, *arms*, the firelock must be thrown with the right hand, in one motion, and with as little appearance of effort as possible, into its proper position on the left shoulder. The hand crosses the body in so doing; but must be instantly withdrawn.

Present Arms. First, seize the firelock with the right hand, beneath the guard, turning the lock to the front, but without moving it from the shoulder; second, bring it to the poise, seizing it with the left hand, the fingers extended along the sling, the wrist upon the guard, and the point of the left thumb equal in height with the eyes; third, bring down the firelock, with a quick motion, as low as the right hand will admit without constraint, drawing back the right foot at the same instant, so that the hollow of it may touch the left heel. The firelock in this position is to be totally supported in the left hand, the body to rest entirely on the left foot, both knees to be straight.

Shoulder Arms. First, by a turn of the wrist, bring the firelock to its proper position on the shoulder, as described above, the left hand grasping the butt; second, quit the right hand, and bring it briskly down to its place at the side.

Charge Bayonets. First, at one motion throw the firelock from the shoulder across the body, to a low diagonal recover, a position generally denominated *porting arms*, or *preparing for the charge*, in which the lock is to be turned to the front, and at the height of the breast, the muzzle slanting upwards, so that the barrel may cross opposite the point of the left shoulder, with the butt proportionally depressed. The right hand grasps the small of the butt, and the left holds the piece at the swell, close to the lower pipe, the thumbs of both hands pointing towards the muzzle; second, make a half face to the right, and bring down the firelock to nearly a horizontal position, with the muzzle inclining a little upwards, and the right wrist resting against the hollow of the thigh, just below the hip. N. B. The first motion of the charge is the position which the soldier will, either from the shoulder, or after firing, take, in order to advance on an enemy whom it is intended to attack with bayonets fixed. The word of command, for that purpose, is, *Prepare to charge*. The second position is that which the front rank takes when arrived at a few yards distance only from the body to be attacked. The first motion of the charge is also that which sentries are to take, when challenging any persons who approach their posts.

Shoulder Arms. First, face to the front, and throw up the piece into its position on the shoulder, by a turn of the right wrist, instantly grasping the butt, as above described, with the left hand; second, quit the firelock briskly with the right hand, bringing it to its proper place by the side.

The men must likewise be taught to *support arms* at three motions, throwing the first and second nearly into one. First, they seize the small of the butt under the lock with the right hand, bringing the butt in front of the groin, and keeping the lock somewhat turned out; second, they bring their left arm

under the cock; third, they quit the right hand. In *carrying arms*, from the support, the motions are exactly reversed. In marching any distance, or in standing at ease when supporting, the men are allowed to bring their right hand across the body, to the small of the butt, which latter must, in that case, be thrown still more forward; the fingers of the left hand being uppermost, must be placed between the body and the right elbow. The right hands are to be instantly removed, when the division halts, or is ordered to dress by the right. In regard to the motions of *securing*, *grounding*, and *trailing*, as well as *piling arms*, it will be sufficient for the soldiers to be taught to perform them in the quickest and most convenient method. *Unfixing bayonets* is to be done from the order, in the same manner as fixing them.

Sentries posted with shouldered arms, are permitted afterwards to *support*, but not to slope them. On the approach of an officer, they immediately *carry* their arms, and put themselves into the proper position; not at the instant he passes, but by the time he is within twenty yards of their post, so that they may be perfectly steady before he comes up. If a field officer, he is entitled to the *present arms*. Corporals marching with reliefs, or commanding detachments or divisions, will carry their arms *advanced*.

VII. *The Platoon Exercise*. When perfect in the manual, the troops are next to be taught this part of their duty, and the manner in which to execute the several firings. The recruit standing at shouldered arms, the first word given is:

Make Ready. This is done by bringing the firelock to the recover, and instantly cocking.

Present. Slip the left hand along the sling as far as the swell of the firelock, and bring the piece down to the present, stepping back about six inches to the rear with the right foot.

Fire; Having fired, drop the firelock briskly to the priming position, and half cock.

Handle Cartridge. First, draw the cartridge from the pouch; second, bring it to the mouth, holding it between the forefinger and thumb, and bite away the top of it.

Prime. First, shake a little powder into the pan; second, shut the pan with the three last fingers; third, seize the small of the butt with the same three fingers.

Load. First, face to the left on both heels, so that the right toe may point directly to the front, and the body be a very little faced to the left, bringing at the same time the firelock round to the left side, without sinking it. It should, while in this position, be nearly perpendicular (having the muzzle only a small degree brought forward); and, as soon as it is steady there, it must instantly be forced down within two inches of the ground, the butt nearly opposite to the left heel, and the firelock itself somewhat sloped, and directly to the front. The right hand at the same instant catches the muzzle in order to steady it; second, shake the powder into the barrel, putting in after it the paper and ball; third, seize the top of the ramrod with the fore-finger and thumb.

Draw Ramrods. First, force the ramrod half out, and seize it, back-handed, exactly in the middle; second, draw it entirely out, and turning it with the whole hand and arm extended from you, put it one inch into the barrel.

Ram down Cartridge. First, push the ramrod down, holding it, as before, exactly in the middle, till the hand touches the muzzle; second, slip the fore-finger and thumb to the upper end, without letting the ramrod fall further into the barrel; third, push the cartridge well down to the bottom; fourth, strike it two very quick strokes with the ramrod.

Return Ramrods. First, draw the ramrod half out, catching it back-handed; second, draw it totally out, turning it very briskly from you, with the arm extended, and put it

into the loops, forcing it as quick as possible to the bottom; then face to the proper front, the finger and thumb of the right hand holding the ramrod, as in the position immediately previous to drawing it, and the butt raised two inches from the ground.

Shoulder Arms. Strike the top of the muzzle smartly with the right hand, to fix the bayonet and ramrod more firmly, and at the same time throw it nimbly up at one motion, to the shoulder. N. B. Though the butts are not to come to the ground in sailing about, as accidents may happen from it, yet they are permitted, while loading, to be so rested; but it must be done without noise, and in a manner imperceptible in the front.

In priming and loading quick, 1st, bring the firelock down in one brisk motion to the priming position, the thumb of the right hand placed against the pan cover or steel, the fingers clenched, and the elbow a little turned out, so that the wrist may be clear of the cock. 2d, Open the pan, by throwing up the steel with a strong motion of the right arm, turning the elbow in, and keeping the firelock steady in the left hand. 3d, Bring your hand round to the pouch, and draw out the cartridge. The rest as above described; except that in the quick loading, all the motions are to be done with the utmost dispatch possible, the soldiers taking their time from the *slugel-man* in front, for casting about and shouldering only.

In firing three deep, the priming position for the front rank is the height of the waistband of the breeches; for the centre rank, about the middle of the stomach; and for the rear rank, close to the breast. The firelock in all these positions is to be kept perfectly horizontal.

As Front Rank kneeling—make ready. Bring the firelock briskly up to the recover, catching it in the left hand, and, without stopping, sink down with a quick motion on the right knee, keeping the left foot fast, the butt of the firelock at the same moment falling upon the ground. Then cock, and instantly seize the cock and steel together in the right hand, holding the piece firm in the left, about the middle of that part which is between the lock and the swell of the stock; the point of the left thumb to be close to the swell, and pointing upwards. As the body is sinking, the right knee is to be thrown so far back, that the left leg may be right up and down, the right foot a little turned out, body straight, and the head as much up as if shouldered. The firelock must be upright, the butt about four inches to the right of the inside of the left foot.

Present. Bring the firelock down firmly to the *present*, by sliding the left hand to the full extent of the arm along the sling, without letting the motion tell; the right hand at the same time springing up the butt by the cock so high against the right shoulder, that the head may not be too much lowered in taking aim; the right cheek to be close to the butt, the left eye shut, and the middle finger of the right hand on the trigger. Look along the barrel with the right eye, from the breech-pin to the muzzle, and remain steady.

Fire. Pull the trigger strong with the middle finger, and, as soon as fired, spring up nimbly upon the left leg, keeping the body erect, and the left foot fast, and bringing the right heel to the hollow of the left. At the same instant, drop the firelock to the priming position, half cock, handle cartridge, and go on with the loading motions as before described.

As Centre Rank—make ready. Spring the firelock briskly to the recover. As soon as the left hand seizes it above the lock, raise the right elbow a little, placing the thumb of that hand upon the cock, with the fingers open on the plate of the

the lock, and then, as quick as possible, cock the piece, by dropping the elbow, and forcing down the cock with the thumb. Step at the same time with the right foot a moderate pace to the right, and keeping the left fast, seize the small of the butt with the right hand. The piece must be held in this position perpendicular, and opposite the left side of the face, the butt close to the breast, but not pressed, the body straight and tall to the front, and the head erect.

Present, as in the foregoing explanation.

Fire. Pull the trigger strong with the middle finger; and, as soon as fired, bring the firelock to the priming position. Prime and load as before, with this difference only, that the left foot is to be drawn up to the right, at the same time that the firelock is brought down to the priming position; and that, immediately after the firelock is thrown up to the shoulder, the men spring to the left again, and cover their file leaders.

As Rear Rank—make ready. Recover and cock as before directed for the centre rank. As the firelock is brought to the recover, step briskly to the right a full pace, at the same time placing the left heel about six inches before the point of the right foot. The body to be kept straight, and as square to the front as possible.

Present, as in the foregoing explanation.

Fire, as before; remembering only the difference of the priming position for this rank. After firing and recovering the shoulder, the men step as the centre rank does.

In firing with the front rank standing, that rank makes ready, &c. as mentioned in the first part of the platoon exercise. The platoon exercise is always to be performed with ranks closed, except at the drill.

VIII. *Firings*. When the recruits have acquired the management of their arms, and are perfect in the motions of the manual and platoon exercises, they will be instructed in closed ranks, at firing, 1st, direct to their front; 2dly, obliquely to the right and left; and, 3dly, by files.

IX. *Marching to the front and rear*. The division, or squad, is to be particularly well dressed, files correct, arms carried, the rear ranks covering exactly, and each individual to have his just attitude and position, before the squad is ordered to move. The march will be made by the right or left flank, and a proper trained man will therefore conduct it. The word *division* may be given as a caution; and at the word *march*, each man steps forward a full pace. The recruit must not turn his head to the hand to which he is dressing, as a turning of the shoulders would undoubtedly follow. His elbows must be kept steady, without constraint: if they are opened from his body, the next man must be pressed upon; if they are closed, there arises an improper distance, which must be filled up. In either case, waving on the march will take place, and is therefore to be avoided. The going to the right, or left about, in march, is not to be at first practised, but the squad is to halt, front by command, and then march. As the being able to march straight forward is of the utmost consequence, the officer commanding the drill will take every pains to perfect his squad in it. For this purpose, he will often go to the rear, place himself behind the flank file which regulates the march, and take a point or object exactly in front of that file. He will then command, *march*; and remaining in his place, will direct the advance of the squad, by keeping the flank file always in a line with the object. It is also from behind he will sooner perceive the leaning back of a shoulder, or the bringing it forward; faults which ought instantly to be rectified, as productive of the worst consequence in a line, where one man, by bringing forward a shoulder, may change the direction of the march, and oblige the wing of

a battalion to run, in order to keep dressed. In short, it is impossible to labour too much at making the soldier march straight forward, keeping always the same front as when he stepped off. This is effected by moving solely from the haunches, keeping the body steady, the shoulders square, and the head to the front; and will without difficulty be attained by a strict attention to the rules for marching, and a careful observance of an equal length of step, and an equal cadence or time of march.

Changing from ordinary to quick time, and from quick to ordinary, must always be preceded by a halt. Although this may not appear essential for the movements of a division or battalion, it is absolutely so for those of a larger body, and is therefore required in small ones. Turning on the march, in order to continue it, though inaccurate and improper for a large body, is necessary, and must often be allowed, in the movements of small divisions in file or front, when connected with others in line or column. As helps for fixing the true cadence of the march, the plummet must often be resorted to. The words *left*, *right*, may, when necessary, be repeated; slowly for ordinary, and more rapidly for quick time. Strong taps of the drum, regulated by the plummet, may be allowed to be given immediately before the word *march*, to imprint the required measure on the mind of the recruit; but they are on no account, or in any situation, to be given during the march.

X. *Open and close Order, on March*. The squad, when moving to the front in ordinary time, receives the word, *Rear ranks take open order*; on which the front rank continues its march without altering the pace, and the centre and rear ranks mark the time, viz. the centre once, and steps off at the second pace; the rear rank moving forward on the third. On the word *Rear ranks take close order*, the centre and rear ranks step nimbly up to close order, and instantly resume the pace at which the first rank has continued to march.

XI. *March in File to a Flank*. The accuracy of the march in file is so essential in all deployments into line, and in the internal movements of the divisions of the battalion, that the soldier cannot be too much exercised to it. The whole battalion, as well as its divisions, is required to make this flank movement, without the least opening out, or lengthening of the file, and in perfect cadence and equality of step. After facing, and at the word *march*, the whole squad steps off at the same instant, each replacing, or rather overstepping the foot of the man before him, i. e. the right foot of the second man comes within the left foot of the first, and thus of every one; more or less overlapping, according to the closeness or openness of the files, and the length of step. The front rank will march straight along the given line, each soldier of that rank looking along the necks of those before him; never to the right or left; otherwise a waving of the march will take place, and of course the loss and extension of line and distance, whenever the body returns to its proper front. The centre and rear ranks must look to, and regulate themselves by their leaders of the front rank, and always dress in their file. Although file marching is generally in quick, yet it must also be practised in ordinary time. The above position of feet takes place in all marching in front, where the ranks are close, and locked up. With a little attention and practice, this mode of marching, apparently so difficult, will be found by every soldier to be easier than the common method of marching by files, when, on every halt, the rear must run up to gain the ground it has unnecessarily lost.

XII. *Wheeling in File*. The squad, when marching in file, must be accustomed to wheel its head to either flank; each

each file following in succession, without losing or increasing distance. On this occasion, each file makes its separate wheel, on a pivot moveable in a very small degree, but without altering its time of march, or the eyes of the rear ranks being turned from their front rank. The front rank men, whether pivot-men or not, must keep up to their distance; and the wheeling men must take a very extended step, and lose no time in moving on.

XIII. *Oblique Marching in Front.* When the squad is marching in front, and receives the word *to the right oblique*, each man, the first time he raises the right foot, will, instead of throwing it straight forward, carry it in the diagonal direction, as has been already explained in § 8. of the drill without arms; taking care not to alter the position of his body, shoulders, or head. The greatest attention is to be paid to the shoulders of every man in the squad, that they remain parallel to the line on which they first were placed, and that the right shoulders do not fall to the rear, which they are very apt to do in obliquing to the right, and which immediately changes the direction of the front. On the word *forward*, the incline ceases, and the whole march forward. In obliquing to the left, the same rules are to be observed, with the difference of the left leg going to the left, and attention to keeping up the left shoulder. The same instructions that are given for ordinary time, serve also for quick time; but this movement, though it may be made by a small division, cannot be required from a larger body. Obliquing to the right is sometimes to be practised with eyes to the left; and obliquing to the left, with eyes to the right; as being absolutely necessary on many occasions: for if one of the battalions of a line in advancing be ordered to oblique to the right or to the left, the eyes must still continue turned towards its centre.

XIV. *Oblique Marching in File.* In obliquing to the right or left by files, the centre and rear rank men will continue looking to their leaders of the front rank. Each file is to consider itself as a rank entire, and is to preserve the same front, and position of the shoulders, during the oblique, as before it began. This being a very useful movement, recruits are to be often practised in it.

XV. *Wheeling forward from the Halt.* The directions already given for the wheeling of a single rank, are to be strictly attended to in this wheel of the squad. On the word *right*, or *left wheel*, the rear ranks, if at one pace distance, lock up. At the word *march*, the whole step together in the quickest time, and the rear ranks, during the wheel, incline so as to cover their proper front rank men. At the word *halt*, the whole remain perfectly steady.

XVI. *Wheeling backward.* The squad must be much practised in wheeling backward in the quickest time. In this wheel, the rear ranks may preserve their distance of one pace from each other. Great attention should be paid to prevent the recruits from fixing their eyes on the ground.

XVII. *Wheeling from the March.* The directions for wheeling on a halted, and on a moveable pivot, have already been given under the drill without arms. The squad should now be practised in both, until thoroughly confirmed in those movements.

XVIII. *Stepping out, &c.* The squad must likewise be practised in *stepping out*, *stepping short*, *marking time*, *changing the feet*, *the file step*, and *stepping back*; the instructions for which have been fully detailed in the first part of the drill.

It can neither be too strongly inculcated, nor too often remembered, that upon the correct equality of march, established and practised by all the troops of the same army, every just movement and manœuvre depend. If this is not

attended to, disunion and confusion will necessarily take place on the junction of several battalions in corps; although, taken individually, each may be in most respects well trained. It is in the original instruction of the recruit and squad, that this great point is to be laboured at and attained. The time and length of step, on all occasions, are prescribed. The time is infallibly ascertained by the frequent corrections of the plummet, which, when so applied, will soon give to each man that habitual measure so much desired. Every driller must therefore have it at hand; and, as already observed, before any squad or larger body is put in march, five or six strong taps of the drum may be given, in exact time, as regulated by the plummet, which will imprint the true measure on each ear, and prepare for taking an accurate step at the word *march*. The length of step is only to be acquired by repeated trial; and therefore, before the recruit is put in motion, each instructor should ascertain the space on which he is to drill his men; he will therefore (supposing that he himself is accurate in his paces, and that there is ground for that purpose) mark out an oblong square of forty paces by twenty or thirty, the corner of which he will ascertain by halberts, stones, or any other visible manner. Along the sides of this figure he will march the pivot flank of his squad, making correct wheels and hairs at the angles. The time of march being exactly ascertained, he will then see that the sides of the oblong are gone over at the known number of steps; and if there be any inaccuracy, he will lengthen or shorten the step, till the squad marches with the utmost precision, every man preserving his just position, and all the other indispensable attentions in marching being strictly observed. Where there is a sufficiency of ground, the squads will occasionally march over larger spaces; but the distances should in the same manner be exactly determined, so that there may be no doubt as to the true length of the step. In proportion to the strength of squads or drills, one or more formed soldiers should accompany each, to march on the flank, give distances, and in other points regulate the motions of the drill.

Formation and Exercise of the Platoon, or Company.

The recruit being thoroughly grounded in all the preceding parts of the drill, is now to be instructed in the movements of the platoon, as a more immediate preparation for his joining the battalion. For this purpose, from ten to twenty files are to be assembled, formed, and told off in the following manner, as a company in the battalion.

I. The platoon falls in three ranks, at close order, with shouldered arms; the files lightly touching, but without crowding. Each man will then occupy a space of about 22 inches. The commander of the platoon takes post on the right of the front rank, covered by a serjeant in the rear rank. The other serjeants will form a fourth, or supernumerary rank, three paces from the rear rank. The platoon will be told off into subdivisions, and, if of sufficient strength, into four sections; but as a section should never be less than five files, it will often happen that, for the purposes of march, three sections only can be formed. The four best-trained soldiers are to be placed in the front rank, on the right and left of each subdivision. When thus formed, the platoon will be practised in opening and closing of ranks; dressing to the front, to the rear, or in an oblique direction, by the right or left; and exercised in the several motions of the firelock. Close order is the chief and primary order in which the battalion and its parts at all times assemble and form. Open order is only regarded as an exception from it, and occasionally used in situations of parade and skew. In close order, the rear ranks are closed up to within one pace; the length of which is to be taken from

the heels of one rank to those of the next. At open order, they are two paces distant from each other.

II. *Marching to the Front.* In the drill of the platoon, the person instructing must always consider it as a company in battalion, and regulate all its movements upon that principle. He will therefore, before he puts it in motion to front or rear, indicate which flank is to direct, by giving the word *Eyes Right*, or *Eyes Left*, and then *March*. Should the right be the directing flank, the commander of the platoon himself will fix on objects to march upon, in a line truly perpendicular to the front of his corps. When the left flank is ordered to direct, he and his covering serjeant will shift to the left of the front rank, and take such objects to march upon. To march on one object only, and to preserve a straight line, is an operation not to be depended upon. The conductor of the platoon therefore, before the word to march is given, will endeavour to remark some distinct object on the ground in his own front, and perpendicular to the directing flank. He will then observe some nearer and intermediate point in the same line, such as a stone, tuft of grass, &c. These he will move upon with accuracy; and as he approaches the nearest of those points, he must from time to time chuse fresh ones, in the original direction, which he will by this means preserve, never having fewer than two such points to move upon. If no object in the true line can be ascertained, his own squareness of person must determine the direction of the march. A person placed in the rear of a body can, more readily than if posted in its front, determine the line which is perpendicular to that front; and, could we suppose ranks and files perfectly correct, the prolongation of each file would be a perpendicular to the front of the body. As the march of every corps, except in the case of inclining, is made on lines perpendicular to its then front, each individual composing that corps must in his person be placed and remain perfectly square to the given line; otherwise he will naturally and insensibly move in a direction perpendicular to his own person, and thereby open out or close in according to the manner in which he is turned from the true point of his march. If the distortion of a single man (and all turnings of the head do so distort him) operates in this manner, it may easily be imagined what that of several will occasion, each of whom is marching on a different front, and whose lines of direction are crossing each other. Accuracy and squareness of position, the equality of cadence and step, the light touch of the files which is never to be relinquished, just distances, and true lines of movement, will give, without apparent constraint, the head being turned, or the least trouble taken in dressing, the most decisive exactness in the marches and operations of the largest bodies.

The platoon, during its march in line, will occasionally be ordered to *step out*, *mark time*, *open* and *close ranks*, and *oblique*, as already described.

III. *Side Step.* The side or closing step must also be frequently practised. It is very necessary and useful on many occasions, when halted, and when a very small distance is to be moved to either flank: for instance, to open or close files; to join one division to, or open it from, another; to regain an interval in line; to move a whole battalion or parade twenty or thirty paces to a flank; to regulate distances between close columns, before deploying, &c. Alterations made in this manner are imperceptible from the front, and better made than by facing and file-marching. The words of command must be decided and strong. When the whole platoon is to close; at the word, *to the Right—Close*, the platoon officer takes one step to the front, and instantly faces about, the covering serjeant replacing him. On the word

March, the whole move together. On the *Halt*, the platoon officer resumes his place, having stepped in the same manner as the men, but fronting them, and thereby assisted in preserving the direction.

IV. *Back Step.* The platoon must be accustomed, at the halt on the words *Back Step—March*, to step back any ordered number of paces in the ordinary time and length, as it is an operation that may be sometimes required from a battalion.

V. *File Marching.* In marching by files, the commander of the platoon will lead the front rank. If therefore the movement is by the left, on the word *to the Left—Face*, he and his covering serjeant will instantly shift to the left flank of the division. At the word *Quick—March*, the whole steps off together; and on the *Halt, Front*, the leader and his serjeant will return to their posts on the right.

VI. *Wheeling from a Halt.* In wheeling, whether forward or backward, from a halt, the commander of the platoon, on the word *Right* or *Left Wheel*, moves out, and places himself one pace in front of the centre of his platoon. During the wheel, he turns towards his men, and inclines towards that flank which has been named as the directing or pivot one; giving the word *Halt—Dress*, when his wheeling man has just completed the required degree of wheel. He then squares his platoon, but without moving what was the standing flank, and takes his post on the now directing flank.

VII. *Wheeling forward by Subdivisions from Line.* On the word *By Subdivisions, to the Right, Wheel*, the commander of the platoon places himself one pace in front of the centre of the right subdivision; at the same time, the men on the right of the front rank of each subdivision face to the right. At the word *March*, each subdivision steps off in wheeling time, observing the directions above given for wheeling forward. The commander of the platoon, turning towards the men of the leading subdivision, and inclining to its left (the proper pivot flank), gives the word *Halt—Dress*, for both subdivisions, as his wheeling man is taking the last step that finishes the wheel square; and instantly posts himself on the left, the pivot flank. The covering serjeant, during the wheel, goes round by the rear, and takes post on the pivot flank of the second subdivision. It is to be observed, that the commander of the platoon invariably takes post with the leading subdivision; therefore, when the platoon wheels by subdivisions to the left, the commander of the platoon moves out to the centre of the left subdivision, and during the wheel, inclines towards the right, now become the proper pivot flanks of the subdivisions. The proper pivot flank in column, is that which, when wheeled up to, preserves the divisions of the line in the natural order, and to their proper front; the other is denominated the *reverse* flank. In column, divisions cover and dress to the proper pivot flank; to the left when the right is in front, and to the right when the left is in front.

VIII. *Wheeling backward by Subdivisions from Line.* The platoon will also break into open column of subdivisions by wheeling backwards. When the right is intended to be in front; at the word, *By Subdivisions, on your left backwards Wheel*, the commander of the platoon moves out briskly, and places himself in front of the centre of the right subdivision; the man on the left of the front rank of each subdivision at the same time faces to the right. On the word *March*, each subdivision wheels backward in quickest time. During the wheel, the commander of the platoon turns towards his men, inclining at the same time to the left, or pivot flank; and on completing the wheel, gives the word *Halt—Dress*, to both divisions. He and his covering

covering serjeant then place themselves on the left flanks of their subdivisions. It may be considered as a rule almost general (the reasons for which are subsequently given), that all wheels of the battalion or line (when halted, and when the divisions do not exceed sixteen or eighteen files) into column, should be backward; and all wheels from column into line, forward. The only necessary exceptions seem to be in narrow ground where there is not room for such wheels.

IX. *Marching on an Alignment, in open Column of Subdivisions.* The platoon having wheeled backwards by subdivisions from line, as just stated, and a distant marked object in the prolongation of the two pivot flanks being taken, the commander of the platoon, who is now on the pivot flank of the leading subdivision, immediately fixes on his intermediate points to march on. On the word *March*, both divisions step off at the same instant; the leader of the foremost corps marching with the utmost steadiness and equality of pace on the points he has taken; and the commander of the second division preserving the leader of the first in an exact line with the distant object, at the same time he keeps the distance necessary for forming from the preceding division, which distance is to be taken from the front rank. These objects are in themselves sufficient to occupy the whole attention of the leaders of the two divisions; therefore they must not look to, nor endeavour to correct, the march of their men, which care must be entirely left to the non-commissioned officers of the supernumerary rank.

X. *Wheeling into Line from open Column of Subdivisions.* The platoon being in open column of subdivisions, marching at the ordinary step on the alignment, receives the word *Halt* from the instructor of the drill. Both divisions instantly halt, and the instructor sees that the leaders of the divisions are correct on the line in which they have moved. He then gives the word (supposing the right of the platoon to be in front), *By Subdivisions, to the left wheel into Line.* On this the commander of the platoon goes to the centre of his subdivision; the two pivot men face to their left, exactly square with the alignment, and a serjeant runs out and places himself in a line with them, so as to mark the precise point at which the right flank of the leading subdivision is to halt, when it shall have completed its wheel. At the word *March*, the whole wheel up in quickest time. During the wheel, the commander of the platoon, turning towards his men, inclines to the wheeling flank, and gives the word *Halt—Dress*, the moment the wheel of the division is completing. He also, if necessary, corrects the internal dressing of the platoon on the serjeant and pivot men. This dressing must be quickly made; and when done, the commander of the platoon gives the word *Eyes Front*, in a moderate tone of voice, and resumes his post in line. In all wheels of the divisions of a column (either from the halt or from the march) that are made on a halted pivot, the flank firelock of the front rank on the hand wheeled to, is such pivot; not the officer who may be on that flank, and whose business is to conform to it. All wheels by subdivisions or sections from line into column, or from column into line, are performed on the word given by the commander of a battalion, when the whole of a battalion is at the same instant so to wheel; or on the word given by the captain of the company, when companies singly, or successively, so wheel. They are not to be repeated by the leaders of its divisions.

XI. *In Open Columns of Subdivisions, wheeling into an Alignment.* The platoon being in open column of subdivisions, marching in ordinary time; when its leading division arrives at the ground, where the wheel is to commence, it receives the word, *Right or Left Wheel*, from its commander. On this the rear ranks, if at one pace distance, lock up;

the flank front-rank man alone halts, and faces into the new direction, while the others quicken their pace to the wheeling time, and regulate their step by the outward hand to which they have turned their eyes, until the wheel is completed. He then gives the word *Halt—Dress*, for his division to dress to the hand it is to move by; and whenever the second division, which has continued to advance in ordinary time, arrives close to the wheeling point, he gives his division the word *March*, and moves on in ordinary time, so as its rear rank does not occasion even a momentary stop to the division behind it, which at that moment receives the word *Wheel*, then *Halt—Dress*, and finally *March*, whenever the leading division has gained its proper distance from it. The officer conducting the leading and every other division of the column in march on any given point or object where it is to wheel into a new direction, and to its proper pivot hand on a halted pivot, always stops at that point or object close on his outward hand, and gives the word *Wheel*, when the front rank of his division has taken one pace beyond such object. He thus allows space for his own person, when the wheel is finished, to move on close behind the new direction of march. But if the proper pivot flank is to be the wheeling one, each commander of a division gives his word *Wheel*, as he successively arrives at such a distance from the point on which he has moved, as that at the completion of the wheel, his division may halt perpendicular to the new line, but with the given point of course behind the proper pivot; and that he also, in his own person, be on the new direction, prepared to give his word *March*, and to proceed. The rear ranks, if at one pace distance, must close up at the word *Wheel*; and during the wheel, they incline so as to cover their proper front-rank men. The subdivisions must take care that they continue their march correctly upon, and wheel exactly at the point where the leading one wheeled, and that they do not shift to either flank, which without much attention they are apt to do. In this manner, the subdivisions succeed each other; and if the words of command be justly given, no stop made on arriving at the wheeling point, the wheels performed at an increased time and step, and the proper halt, dressing, and pause, be made after the wheel, no extension of the column will take place, but the just distances between the divisions will be preserved. The officer conducting the directing flank of a division may, during the wheel, be advanced one or two paces before it, and remains so, facing to the flank, that he may the more critically be enabled to give the word *Halt*, at which instant he will again place himself on the flank, ready to judge his distance, and to give the word *March*.

XII. *In Open Column of Subdivisions, wheeling into a new Direction on a moveable Pivot.* The commander of the leading subdivision, when at a due distance from the intended new direction, will give the word *Right or Left Shoulders Forward*; and he himself carefully preserving the rate of march, without the least alteration of step or time, will begin to circle in his own person from the old into the new direction, so as not to make an abrupt wheel, or that either flank shall be stationary. The rest of his division, on the principle of dressing, will conform to the direction he is giving them; when this is effected, he will give the word *Forward*. The leader of the second subdivision, when he arrives at the ground on which the first began to wheel, will in this manner follow the exact tract of the first, always preserving his proper distance from him. Thus, without the constraint of formal wheels, a column, when not confined on its flanks, may be conducted in all kinds of winding and changeable directions; for, if the changes be made gradual and circling, and that the pivot leaders of divisions

divisions pursue their proper path, at the same uniform equal pace, the true distances will be preserved, which is the great regulation object on this occasion, and to which every other must give way.

XIII. *Countermarch by Files.* The platoon, when it is to countermarch, must always be considered as a division of a battalion in column. The instructor of the drill will therefore, previous to his giving the caution to countermarch, signify whether the right or left is supposed to be in front, that the commander of the platoon and his covering serjeant may be placed on the pivot flank, before such caution is given; as it is an invariable rule in the countermarch of the divisions of a column by files, that the facings be made from the flank, then the pivot one, to the one which is to become such. On the word *To the Right or Left Face*, the platoon faces; the commander of it immediately goes to the other flank; and his covering serjeant, advancing to the spot which he has quitted, faces to the right about. At the word *Quick March*, the whole, except the serjeant coverer, steps off together; the platoon officer wheeling short round the rear rank (viz. to his right, if he has shifted to the right of the platoon; or to his left, if he remains on the left of it); and proceeds, followed by the platoon in file, till he has conducted his pivot front-rank man close to his serjeant, who has remained immovable. He then gives the words *Halt, Front, Dress*; squares, and closes his platoon on his serjeant, and then replaces him. All countermarches by files necessarily tend to an extension of the files. Unity of step is therefore absolutely indispensable, and the greatest care must be taken, that the wheel of each file be made close, quick, and at an increased length of step of the wheeling man, so as not to retard or lengthen out the march of the whole.

XIV. *Wheeling on the Centre of the Platoon.* The platoon must be accustomed to wheel upon its centre, half backward, half forward, and to be pliable into every shape which circumstances can require of it; but always in order, and by a decided command. The words of command are, *Platoon—on your Centre, to the Right Wheel, to the Left Wheel; to the Right about wheel; to the Left about wheel; &c.* When the wheel is to be made to the right, or right about, the right half platoon is the one to wheel backward, and the left forward. The reverse will take place when the wheel is to be made to the left, or to the left about. On the word *March*, the whole move together in the quickest time, regulating by the two flank men, who, during the wheel, preserve themselves in a line with the centre of the platoon. As soon as the required degree of wheel is performed, the commander of the platoon gives the word *Halt—Dress*, and instantly squares it from that flank on which he himself is to take post.

XV. *Oblique Marching.* The instructor of the drill will have the oblique march frequently practised in platoon, in subdivisions, and in file. He will see, when in divisions, that the rear ranks lock well up, and cover exactly; when in file, that the exact distances are preserved between the files; and in both cases, that the platoon, during its march, continues parallel to the position from which it commenced obliquing.

XVI. *Increasing and diminishing the Front of an Open Column, when halted.* 1. *Increasing.* The company standing in open column of subdivisions (suppose the right in front) receives from the instructor of the drill the caution to form platoon. The commander of the platoon instantly orders *Rear Subdivision, to the Left oblique—Quick March.* When it has obliqued, so as to open its right flank, i. e. when its right flank has room to march past the left flank of the division that was in its front he gives the word *Forward*;

and, on its arriving in a line with the first division, he orders *Halt—Dress*, and takes post on the left, the pivot flank of the platoon. 2. *Diminishing.* On the cautionary command, from the instructor of the drill, to form *Subdivisions*, the commander of the platoon orders, *Left Subdivision—to the Right Face*; and instantly on facing, the three leading files disengage to the rear, the serjeant coverer running round to head them. On the word *Quick March*, the serjeant conducts the subdivision in file, to its proper distance, in the rear of the first subdivision. The commander of the platoon, having moved to the left flank of the leading division, as soon as he sees the rear file of the second in a line with his own person, gives the words *Halt—Front and Left—Dress.* The serjeant coverer at the same time moves briskly to his post on the left flank of the rear subdivision, and squares it. It is to be observed as a general rule, in diminishing the front of a column by the doubling of subdivisions or sections, whether the column be halted or in motion, that the subdivision or section on the reverse flank is the one behind which the other subdivisions or sections double. Thus, when the right is in front, the doubling will be in rear of the right division, and *vice versa* when the left is in front; by which means the column is at all times in a situation to form line to the flank, with its divisions in their natural order, by simply wheeling upon the pivot flanks. In increasing the front of a column, the rear subdivisions or sections oblique to the hand the pivot flank is on; so that when the right is in front, the obliquing will be to the left; and the reverse when the left is in front.

XVII. *Increasing and diminishing the Front of an open Column on the March.* 1. *Increasing:* The platoon marching at the ordinary time in open column of subdivisions (suppose the right in front), receives from the instructor of the drill the cautionary command *Form Platoon.* The commander of the platoon instantly gives the words *Left oblique—Quick March*; on which the rear subdivision oblique to the left, and as soon as its right flank is open, receives the word *Forward.* When it gets up to the first subdivision, which has continued to march with the utmost steadiness at the ordinary pace, the commander of the platoon gives the words *Halt—March*, and takes post on the pivot flank. 2. *Diminishing:* When the instructor of the drill gives the caution to form subdivisions, the commander of the platoon immediately orders, *Left Subdivision, Mark Time.* This it does till the right one, which continues its march steadily at the ordinary pace, has cleared its flank. He then orders the left subdivision, *Quick oblique*; and when he perceives that it has doubled properly behind the right one, he gives the word *Forward*, on which it takes up the ordinary march, and follows at its due distance. The same directions that apply to increasing or diminishing by subdivisions, apply equally by sections, which individually repeat the same operations. The words for the subdivisions or sections increasing or diminishing the front of a column, are given by the commander of a company, and not repeated by those of its divisions. Increasing and reducing the front of a column is an operation that will frequently occur in the march of large bodies; and it is of the utmost importance that it be performed with exactness. The instructor of the drill must therefore be particularly attentive, that the transition from one situation to the other be made as quick as possible; that the leading division continues its march at the regular time and length of pace; and that the exact distances between the divisions be accurately preserved. During the operation, the ranks must be well closed, arms carried, and the greatest attention required from each individual.

XVIII. *The Platoon in open Column of Subdivisions to pass a short Defile by breaking off Files.* We suppose the platoon in open column of subdivisions, with the right in front, marching in ordinary time. When the leading division is arrived within a few paces of the defile, it receives from the instructor of the drill an order to break off a certain number of the files (suppose three); the commander of the leading division instantly gives the words, *Three Files on the Left, Right turn.* The named files immediately turn to their right, and wheel out in rear of the three adjoining files. The commander of the subdivision himself closes into the flank of the part formed. When the second subdivision comes to the spot where the first division contracted its front, it will receive the same words of command from its own leader, and will proceed in like manner. Should it be required to diminish the front of the column one or two files more, the commander of the leading division will, as before, order the desired number of files to turn; on which those already in the rear will incline to their right, so as to cover the files now ordered to break off, and which are wheeling out in the manner already prescribed. In this movement, the files in the rear of the subdivisions must lock well up, so as not to impede the march of the succeeding division. As the defile widens, or the instructor of the drill shall direct, the commander of the leading subdivision will order files to move up to the front, by giving the word *One, two, or three Files to the Front*; on which the named files turn to their front, the left, and lengthening their pace, march up, file by file, to the front of their subdivision, and immediately resume the ordinary pace. Those files which are to continue in the rear, will oblique to the left, lengthening also their step, till they cover, and are closed up to the three files on the left flank of their subdivision.

XIX. *Marching in quick Time.* The platoon must frequently be practised to march in quick time, particularly in file, until the men have acquired the utmost precision in this movement, which is essential in all deployments from close column. The platoon will also occasionally be marched in front at the same step, as it may be sometimes required from small bodies.

XX. *Forming to the Front from File.* The platoon, when marching in file, may form to its front, either in sections, sub-divisions, or in platoon. The right flank being supposed to lead, on the word *halt front*, the platoon instantly halts, and faces to its left. The word is then given, *by sections, sub-divisions, or platoon, on your left backwards wheel*; and at the word *march*, the wheel ordered is performed in the manner already directed in sect. viii. But in situations where it may have been necessary to order an extension of files (such as will sometimes occur in marching through the streets of a town), a body thus moving, in order to avoid incorrect distances between the divisions, may form to the front in the following manner, either by platoon, sub-divisions, or sections. On the word *to the front form platoon*, the front rank man of the leading file halts alone, and is instantly covered by his centre and rear rank men. Every other file of the platoon makes a half face to the left, and successively moving up, dresses on the right file. When the commander of the platoon sees it is properly dressed, he gives the word *eyes left*, and places himself on the pivot flank. Should the order have been, *to the front form sections or sub-divisions*, the leading sub-division or section will proceed in the manner already detailed for the platoon. The succeeding sub-divisions or sections will each continue moving on, until its front file arrives at the proper forming distance from the division in its front, when it will receive from

its commander the word *to the front form*, and will instantly form up by files in the manner already described.

XXI. *Forming from File to either Flank.* The platoon marching in file, suppose from the right, has only to halt and front to be formed to the left flank. To form to the right, it will receive the word *to the right form*. The front rank man of the leading file instantly turns to his right, and halts; his centre and rear rank men move round and cover him. All the other files of the platoon make a half turn to their left, and move round successively in a line with the right hand file; the centre and rear rank men of each file keeping closed well up to their file leaders.

XXII. *To form to either Flank from open Column of Subdivisions or Sections.* The platoon marching in the ordinary time in open column of sub-divisions or sections, to form to its left receives the words *halt, left wheel, and form, march, &c.* and proceeds as has already been shewn in sect. x. To form the platoon to its right flank, the instructor of the drill gives the cautionary word of command, *to the right form platoon*; on which the commanders of the several divisions shift to the other flank, and the commander of the leading sub-division or section instantly gives the word to his division, *right wheel*; and when it has wheeled square, he orders *halt, right dress*; goes to the right flank of his division, and dresses it on the intended line of formation. The commander of the other sub-divisions or sections, on the leading one being ordered to wheel, gives the word *to the left oblique*, and gradually inclines so as to be able to march clear of the rear rank of the division forming. This being effected, the word *forward* will be given to each division, and they move on in the rear of the one formed. When the second sub-division or section is arrived at the left flank of the first, its commander gives the word *right wheel*, then *halt, dress up*; on which the division moves up into the line with the one formed; and its commander instantly places himself two or three files from the left of his first division, and dresses his own on it as quickly and as accurately as possible. Thus each succeeding section should proceed, until the whole be formed.

XXIII. *The Platoon moving to the Front to gain Ground to a Flank, by a March in Echelon by Sections.* In the drill of the platoon, when the soldier is completely formed, he may be taught to march in echelon by sections. This is a very useful movement for a battalion or larger body moving in line, that is required to gain ground to a flank, and may be substituted instead of the oblique march. It will be performed in the following manner: the platoon marching to the front in the ordinary time, receives the word *by sections to the right*. The right hand men of the front rank of each section turning in a small degree to their right, mark the time for three paces, during which the sections are wheeling in ordinary time on their pivot men. At the fourth pace, and at the word *forward*, the whole move on direct to the front that each section has now acquired, and the commander of each section having taken post on the right of his division, the platoon continues its march in echelon. On the word *form platoon*, the pivot men mark the time for three paces, turning back in a small degree to the left, their original front; and the sections instantly wheel backward into line. At the fourth pace, the whole move forward. When the platoon is in two ranks only, two paces instead of three will be sufficient to mark time, and to step off at the third instead of the fourth pace.

XXIV. *From three Ranks, forming into two.* The platoon halted, is ordered *form two deep*. The rear rank men of the left sub-division instantly step back one pace. On the word *left face*, the rear rank of both sub-divisions face.

The word *quick march* is then given, on which the men of the rear rank of the left sub-division step short, until those of the right get up to them; they then move on with them in file. As their rear is clearing the left flank of the platoon, the commander, who has shifted to this flank during the movement, gives the words *halt, front, dress up*, instantly dresses them on the standing part of his platoon, and resumes his post on the right. One third or one more sub-division is thus added to the front of the company, which is here supposed standing as one in a battalion column.

XXV. *From two Ranks, forming into three.* The platoon being halted, and told off into three sections, it receives the word *form three deep*; on which the third section instantly steps back one pace. The word *right face* is then given, and the man on the right of its front rank, on facing, disengages a little to his right. On the word *quick march*, the front rank men of the third section step off, those of the other mark the time, till they have passed, and then follow. When the leading man has got to the right of the platoon, the commander gives the word *halt front*; on which, each man halts, faces to his left, and instantly covers his proper file leader.

In pursuance of the foregoing instructions, and on the principles they contain, every company of a battalion must be frequently exercised by its own officers, each superintending a rank, or an allotted part of the whole. On a space of seventy or eighty yards square, every circumstance can be practised that is necessary to qualify it for the operations of the battalion. That space being pointed out by under officers, or other marks, as directed at the latter end of the drill with arms, the company will practise, both at open and close files, without and with arms.

By ranks. 1st, March in single file, by successive ranks, along the four sides of the square; the same by twos. 2d, March and wheel by ranks of fours; file off singly and double up, preserving proper distances, and not quickening on the wheel. 3d, March and wheel by sub-divisions of ranks. 4th, March and wheel by whole ranks. 5th, March to front and to rear, ranks at ten paces asunder. 6th, March the company in a single rank to front and to rear, by a flank and by the centre. 7th, Oblique, by ranks. 8th, Open and close files, and intervals, by the side step. 9th, March in file to either flank. 10th, Ranks successively advance six or eight paces, halt, and dress; ranks successively fall back the same number of paces, halt, and dress. 11th, Advance or retire two or three flank men, the ranks dress to them. 12th, Open and close ranks.

At close ranks and files. 13th, March and wheel in all directions, by sub-divisions and by company; shorten step, and lengthen it; the march to be made both in ordinary and quick time; the wheels to be made in wheeling time. 14th, Advance and retire two or three flank files, and dress to them. 15th, Open and close to the flank by the side step. 16th, Change front by the countermarch by files. 17th, March in file to the flanks, close, and without opening out, form to the front, or to either flank. 18th, March oblique. 19th, Sub-divisions double on the march, and again form up by obliquing. 20th, Wheel backwards by sub-divisions, march along the line to prolong it; form to the flank by wheeling up, or to the front by obliquing. 21st, File from the flank of company to the rear, as in the passage of lines; halt front, close into pivot file, wheel up as in forming line. 22d, From three deep, form two deep. 23d, From two deep, form three deep. 24th, Exercise of the firelock, manual and platoon, by ranks and company. 25th, Firings by files, sub-divisions, and company.

The necessary pauses and formations betwixt these movements in order to connect them, must of course be made. They may be practised in whatever succession shall at the same time be found proper. The greatest precision must be required and observed in their execution, according to the rules already laid down.

Every officer must be instructed in each individual circumstance required of a recruit, or a soldier; also in the exercise of the sword; and accustomed to give words of command with that energy and precision which is so essential. Every officer, on first joining a regiment, is to be examined by the commanding officer; and if he is found imperfect in the knowledge of the movements required from a soldier, he must be ordered to be exercised, that he may learn their just execution. Till he is master of those points, and capable of instructing the men under his command, he is not to be permitted to take the command of a platoon in the battalion. Squads of officers must be formed, and exercised by a field officer. They must be marched in all directions; to the front, oblique, and to the flank. They must be marched in line, at platoon distance, and marched as in open column. They must change direction, as in file, and cover anew in column. In these, and other similar movements, the pace and the distances are the great objects to be maintained. From the number of files in division, they must learn accurately to judge the ground necessary for each, and to extend that knowledge to the front of greater bodies. They must acquire the habit of readily ascertaining, by the eye, perpendiculars of march, and the squareness of the wheel. An officer must not only know the post which he should occupy in all changes of situation, the commands which he should give, and the general intention of the required movement; but he should be master of the principles on which each is made, and of the faults that may be committed, in order to avoid them himself, and to instruct others.

These principles are in themselves so simple, that moderate reflection, habit, and attention, will soon shew them to the eye, and fix them in the mind; and individuals, from time to time, when qualified, must be ordered to exercise the battalion, or its parts. The complete instruction of an officer enlarges with his situation, and at last takes in the whole circle of military science. From the variety of knowledge required of him, his exertion must be unremitting, every one striving to make himself master of his own part. Besides the instruction peculiar to the non-commissioned officers, they should be exercised in the same manner as the officers are, as they are frequently called on to replace them. The necessity also of order, headiness, silence, and of executing every thing deliberately, and without hurry, should be strongly inculcated on the infantry soldier.

Formation of the Company.

The company is always to be sized from flanks to centre. It is formed three deep. The files lightly touch, when firelocks are shouldered and carried, but without crowding, and each man will occupy a space of about twenty-two inches.

Close order is the chief and primary order, in which the battalion and its parts at all times assemble and form. Open order is only regarded as an exception from it, and occasionally used in situations of parade and shew. In close order, the officers are in the ranks, and the rear ranks are closed up within one pace. In open order, the officers are advanced three paces, and the ranks are two paces distant from each other. Each company is a platoon. Each company forms two subdivisions, and also four sections. But as sections should never be less than five files, it will happen, where

where the companies are weak, that they can only, for the purposes of march, form three sections.

When the company is singly formed, the captain is on the right, the ensign on the left, of the front rank, each covered by a serjeant in the rear rank. The lieutenant is in the rear, as also the drummer and pioneers in a fourth rank, at three paces distance. The left of the front rank of each subdivision is marked by a corporal. The right of the left subdivision may be marked by another corporal. When necessary, the places of absent officers may be supplied by serjeants; those of serjeants by corporals; and those of corporals by intelligent men. When the company is to join others, and the battalion, or part of it, to be formed, the ensign and his covering serjeant quit the flank, and fall into the fourth rank, until otherwise placed.

When the company is to take open order from close order, on the command *Rear Ranks—take open Order*, the flank men on the right and left of the rear ranks, step back to mark the ground on which each rank respectively is to halt and dress at open distance. They face to the right, and stand covered. Every other individual remains ready to move. At the word of command *March*, the rear rank dresses front, and the rear ranks fall back one and two paces; each dressing by the right the instant it arrives on its ground. The officers move out in front three paces, and divide their ground. One serjeant is on each flank of the front rank. The pioneer remains behind the centre of the rear rank. The drummer places himself on the right of the right serjeant.

When the company is to take close order from open order, at the word of command *Rear Ranks take close Order*, the officers, serjeants, and drummer face to the right. On the word *March*, the ranks close within one pace, marching one and two paces, and then halting. The officers move round the flanks of the company to their respective posts: the serjeants and drummers fall back, and each individual resumes his place, as in the original close order. The above regards the company when single; but when united in the battalion, other posts are allotted to the drummer and pioneer.

Formation and Order of the Battalion.

A perfect uniformity in the formation and arrangement of all companies and battalions is indispensable for the execution of just and combined movements. The strength of the battalion is ten companies: one grenadier, eight battalion, and one of light infantry, consisting most commonly of three officers, three serjeants, three corporals, two drummers, and fifty-seven privates. When these companies join, and the battalion is formed, there is to be no interval between any of them, grenadier, light company, or other; but every part of the front of the battalion should be equally strong. Each company which makes a part of the same line, and is to act in it, must be formed and arranged in the same manner.

The companies will draw up as follows, from right to left. Grenadiers; first and third captain; fifth and seventh captain; eighth and sixth captain; second and fourth captain; light infantry. The four eldest captains are on the right of the grand divisions. Officers commanding companies or platoons are all on the right of the front rank of their respective companies. The eight battalion companies will compose four grand divisions, eight companies or platoons, sixteen subdivisions, and thirty-two sections, when sufficiently strong to be so divided, otherwise twenty-four, for the purposes of march. The battalion is also divided into right and left wings. When the battalion is on a war establishment, each company is to be divided into two platoons. When the ten companies are with the battalion,

they may then, for the purposes of firing or deploying, be divided into five grand divisions, from right to left. The battalion companies will be numbered from the right to the left, 1, 2, 3, 4, 5, 6, 7, 8; the subdivisions will be numbered 1, 2, of each; the sections will be numbered 1, 2, 3, 4, of each. The files of companies will also be numbered 1, 2, 3, 4, &c. The grenadier and light companies will be numbered separately in the same manner, and with the addition of those distinctions. These several appellations will be preserved, whether faced to front or rear.

The companies must be equalized in point of numbers, at all times when the battalion is formed for field movement; and could the battalions of a line also be equalized, the greatest advantages would arise. But though, from the different strengths of the battalions, this cannot take place, yet the first requisite always must, and is indispensable.

Pl. III. fig. 2. When the battalion is formed in close order, ranks are at the distance of one pace, except the fourth or supernumerary rank, which has three paces. All the field officers, and the adjutant, are mounted. The commanding officer is the only officer advanced in front, for the general purpose of exercise, when the battalion is single; but in the march in line, and in the firings, he is in the rear of the colours. The lieutenant colonel is behind the colours, six paces from the rear rank. The major and adjutant are six paces in the rear of the third and sixth companies. One officer is on the right of the front rank of each company or platoon, and one on the left of the battalion. All these are covered in the rear rank by their respective serjeants, and the remaining officers and serjeants are in a fourth rank behind their companies. It is to be observed, that there are no coverers in the centre rank to the officers or colours.

The colours, which in most regiments are carried by the two youngest ensigns, are placed between the fourth and fifth battalion companies both in the front rank, and each covered by a non-commissioned officer or steady man in the rear rank. One serjeant is in the front rank between the colours; he is covered by a second serjeant in the rear rank, and he by a third in the supernumerary rank. The sole business of these three serjeants is, when the battalion moves in line, to advance and direct the march. The place of the first of those serjeants, when they do move out, is preserved by a named non-commissioned officer, who moves up from the supernumerary rank for that purpose. Of the officers appointed to carry the colours, the eldest carries the king's, the youngest the regimental colour. Whenever the right wing advances or retires, the king's colour accompanies it on its flank, and to it the men's eyes are directed as their point of dressing. In the same manner, the regimental colour accompanies the left wing.

The fourth rank is at three paces distance when halted, or marching in line. When marching in column, it must close up to the distance of the other ranks. The essential use of the fourth rank is to keep the others closed up to the front during the attack, and to prevent any break beginning in the rear. On this important service too many officers and non-commissioned officers cannot be employed. The pioneers are assembled behind the centre, formed two deep, and nine paces from the third rank. The drummers of the eight battalion companies are assembled in two divisions, six paces behind the third rank of their second and seventh companies. The grenadier and light infantry drummers and fifers are six paces behind their respective companies. The music are three paces behind the pioneers in a single rank, and at all times, as well as the drummers and pioneers, are formed at loose files only, occupying no more space than is necessary. The staff of chaplain, surgeon, quarter master, and surgeon's

assistant, are three paces behind the music. Officers in general remain posted with their proper companies; but commanding officers will occasionally make such changes as they may find necessary. Whenever the officers move out of the front rank, in parade, marching in column, wheeling into line, or otherwise, their places are taken by their serjeant coverers, and preserved until the officers again resume them. When the line is halted, and especially during the firings when engaged, the serjeant coverers fall back into the fourth rank, and observe their platoons.

Pl. III. fig. 4. When the battalion is to take open order, at the word of command *Rear Ranks take open Order*, the flank men on the right of the rear ranks of each company step briskly back to mark the ground on which each rank respectively is to halt. They face to the right, and cover as pivots, being regulated and dressed by the adjutant or serjeant major on the right. Every other individual remains ready to move. At the word *March*, the flank dresses face to the front, and the whole move as follows:—The rear ranks fall back one and two paces, each dressing by the right the instant it arrives on the ground. The officers in the front rank, as also the colours, move out three paces. Those in the rear, together with the music, move through the intervals left open by the front rank officers, and divide themselves, viz. the captains covering the second file from the right; the lieutenants the second file from the left; and the ensigns opposite the centre of their respective companies. The music form between the colours and the front rank. The serjeant coverers move up to the front rank, to preserve the intervals left by the officers. The pioneers fall back to six paces distance behind the centre of the rear rank. The drummers take the same distance behind their divisions. The major moves to the right of the line of officers. The adjutant to the left of the front rank. The staff place themselves on the right of the front rank of the grenadiers. The lieutenant colonel and the colonel (dismounted) advance before the colours, two and four paces. The whole being arrived at their several posts, the words *Halt—Dress* are given to the respective companies, and the battalion remains formed for parade in the order in which it should receive a superior officer. When the battalion is reviewed singly, then in order to make more show, the division of drummers may be moved up, and formed two deep on each flank of the line. The pioneers may form two deep, on the right of the drummers of the right; and the staff may draw up on the right of the whole.

When the battalion is to resume close order, the words *Rear Ranks take close Order* is given. The lieutenant-colonel, officers, colours, staff, and music face to the right. The drummers and pioneers, if on the flanks, face to the centre. The serjeants, if in the front rank, face to the right. At the word *March*, the rear ranks close within one pace, moving up one and two paces, and then halting. The music marches through the centre interval. The serjeants, drummers, pioneers, &c. resume their places, each as in the original formation of the battalion in close order. The officers move through and into their respective intervals, and each individual arrives, and places himself properly at his post, in close order.

On particular occasions, and when necessary, officers commanding platoons, who in line are on the right of their platoons, shift to the left to conduct the heads or files, or the pivot flanks of their divisions, in echelon, or in column. When the battalion wheels by companies, or subdivisions, to either flank into column, both colours, and the file of directing serjeants always wheel to the proper front, and place themselves behind the third file of the new pivot.

There is no separate colour reserve, the pioneers, music, &c. sufficiently strengthen the centre; but in the firings, the two files on each side of the colours may be ordered to reserve their fire.

The constant order of the light company, when formed in line, and united with the battalion, is at the same close files as the battalion. Their extended order is an occasional exception. When the light company is detached, and the grenadier company remains, it will be undivided on one flank of its battalion, whenever there are several battalions in line; but when the battalion is single, it is permitted to be occasionally divided on each flank. When the grenadier or light companies are detached, and make no part of the line, they may be formed two deep, if it is found proper.

With a very few obvious alterations, these general rules take place when a company or battalion is permitted or ordered to form in two ranks only; and which, on the low establishment of our battalions, may often be done for the purposes of exercise or movement on a more considerable front. It is also evident that they generally apply, whether the companies are strong or weak, and whether a greater or lesser number of them compose the battalion.

We shall now proceed to give an abstract of the most essential general attentions required in the movements of the battalion, and which may be found more fully detailed in the rules and regulations for the battalion and the line, as published by his majesty's command.

I. *Attentions of the Soldier.*

Quick time is in general confined to wheelings and filings. The other movements of the platoon or battalion are made in *ordinary time*. It is seldom that they will, or ought to be, required at quick time. All *wheelings*, forward or backward, are made quick. Eyes are turned to the wheeling flank, at the word *March*, and not before. The wheeling flank man steps out firm at a pace of thirty-three inches, till he receives the word *Halt*. It is the business of the rest of the rank to keep up to him. Eyes remain in all cases to the wheeling hand, till a new order is given by the commanding officer. All *filings* are made quick, close, and at the lock step. Files are at no time to open out, on occasions of exercise, parade, or manœuvre; but they will often be so permitted and ordered, when marching in the streets; or in common route marching, when the march by divisions cannot so conveniently take place. All *facings* must be accurately made on the left heel. Pivot men must cover carefully and exactly. In wheeling backward, the standing man faces the opposite way to that he does in wheeling forward. Pivots, whether in wheeling into column, or in wheeling into battalion, when once posted are to remain immovable, and do not alter their position in consequence of platoon dressing, nor on any account, but by order of the commanding officer of the battalion, when he finds it necessary to require a more correct dressing from the whole.

The great observance of the soldier in the ranks, and under arms, is the squareness of the shoulders and body, the head to the front, and the eyes only glanced to the point of dressing. When the battalion is halted, and a more accurate dressing is ordered, the head may be a little turned during that operation only, and each man should just distinguish the lower part of the face of the second man from him. Whether in movement, or halted, each man is just to touch, without crowding, his neighbour's arm, towards which he dresses, to depend on that chiefly for his line, and at no time to separate from him. At the word *March*, the stamp of the foot is not to be made, but the first step is to be taken as firm and long as any other, and the body of each man, if in his true position under arms, is prepared for it by an inclination.

forward. On the perfect execution of this, depends much of the accuracy of march. On the word *March*, the first step in all situations is taken with the left foot. When the commanding officer of the battalion gives that word, the whole step off together, whether in line or in column. When he gives the word *Halt*, the whole halt at that instant. At the word *March*, eyes are directed to the pivot flank, if in column; or to the head of the file, if filing; to the colours, if marching in battalion; and in general to that point by which they are conducted. At the word *Halt*, the foot in the air finishes its step, and the other is brought up to it. Eyes remain directed to the pivot flank if marching in column; to the colours, if in line; or to the wheeling flank, if wheeling; and in general to the point to which they were turned when in movement, until a new order commands a new dressing. Whenever the word *Dress* is given by platoon officers to their platoons, eyes are turned to the pivot where the officer is, and from whence he corrects them upon a distant object. In marching in line, each man must preserve his body perfectly square, and just feel the touch of his neighbour, who is nearer than himself to the directing point. The rear ranks are to be well locked up, particularly when firing. In marching in battalion, or when halted, rear ranks will be locked up; but in marching in column, they may in general be at one pace distance. The steps are to be taken firm, and marked.

All alterations in *carrying, supporting arms, &c.* are done by the whole battalion at once, whether in line or column, and not by the divisions of it separately. The commanding officer gives the word, and not the platoon officers; and no such change is at any time made, but in consequence of his command. The men therefore, in all cases, wheel, halt, march, dress, &c. with their arms carried, supported, trailed, or sloped, according as the last-given command directed them. The same is to be observed whenever the battalion, moving in line or in column, changes its time of march.

In column, when the right of the battalion is in front, the left is the pivot flank; and when the left is in front, the right is the pivot. In marching in column, the pivot files of men next to the officers must have great attention in covering, when the movement is made in a straight line, as they are points on which the formation is made; and therefore for that purpose, they must remain close to their pivot officers, who in that situation cover and give distance.

Supported arms should only be allowed when halted in line, or when moving in column. But the march in line, and in general all wheelings up into line, and all formings of the line or dressing it, should be made with *carried arms*, as the only situation which preserves the true distance of files, or can give an accurate line.

II. Covering Platoon Sergeants.

The covering serjeant accompanies and assists the platoon officer in all his movements, and preserves his place in line, or on the pivot flank in column, whenever the officer's duty requires him occasionally to quit it. In battalion, he covers in the rear rank. At open order he moves into the officer's place in the front rank. At close order, he leaves it for the officer to take it. In the march in echelon, he is on the outward flank of the front rank. When the battalion breaks into column to the right or left, the serjeant falls back two paces; and when the wheel is finished, he covers his officer on the pivot flank. When the column marches, if the officer is in front of the platoon, the serjeant is on the pivot of the front rank, and is answerable for the platoon distance; if the officer remains on the pivot flank, the serjeant then falls behind the rear rank, and covers the second file from the pivot. When from column the right in front platoons wheel up to the left into line, the serjeant at the

word *Wheel*, goes to the right of the front rank of the platoon, and wheels up with it, thereby preserving the officer's place. If the wheel is to the right, the serjeant is behind the right file, ready to move up to the officer's place at the conclusion of the wheel. On all occasions, when any platoon, which is then separated, joins in line to one on its right; at that instant must the covering serjeant be on its right, to preserve the place of his officer, who may be employed in dressing his platoon.

When the platoons wheel either into line or into column, the serjeant of the leading platoon runs out, and marks the point in the line of pivots where its flank is to halt. When platoons countermarch in column, the serjeant moves into the officer's place on his quitting it to lead in file, faces to the right about, stands fast, and becomes the pivot point for the front rank leader to close to after the countermarch is finished, and its place is occupied by the officer after dressing his division. When the platoons from columns file, in order to take a new line either to the front or rear; the serjeant of each successively, as it arrives within thirty yards of that line, and no sooner, runs out, takes distance, places himself upon it, and remains as a point to which his officer is to bring and close in the pivot flank man of his platoon, and as a point which the officer himself is afterwards to occupy. Whenever the battalion halts to fire, the serjeants fall back, and in concert with the supernumerary rank, keep the rear ranks well locked up and attentive to their duty. When the battalion again moves, serjeants resume their places. When the battalion is in column of subdivisions, if the officer is ordered to march in front of his platoon, the serjeant is on the pivot of the leading subdivision. If the officer is on the flank of his leading subdivision, the serjeant takes the flank of the second. In column of sections, the serjeant also takes the flank of the second section. In close column, the serjeant is on the flank of the rear rank, behind the officer; and in forming line after the *Halt, Front*, of the platoon, he remains on its outward flank, and marches up with it.

The pioneers, in column of march, are in front; in line, they are formed two deep behind the centre, and nine paces from the rear rank. Drummers, in column of march or close column, are with their companies, and on the flank not the pivot one. In line, the grenadier and light drummers are six paces behind the rear rank of their companies. The battalion drummers are in two divisions, and formed six paces behind the third and seventh companies. In parade, at open order, the drummers preserve their six paces from the rear rank. Whenever the platoon is cautioned to wheel forward or backward any *named* number of paces, the serjeant immediately posts himself before or behind the eighth file from the standing flank, and takes the ordered number of paces; when his platoon has formed, he places himself on its outward flank. The music, in open or close column, are on the flank which is *not* the pivot one; in line, they are in a single line behind the centre, twelve paces from the rear rank. On parade, at open order, they are between the colours and the front rank. Drummers, music, pioneers, &c. will take care not to impede the flank movements of the close column, nor its formation into line, but will get into the rear of their respective battalions, as soon as they are disengaged from each other.

III. Attentions in Platoon Officers.

When the battalion is formed in line, company or platoon officers are all on the right of their platoons. In column, they are on the pivot flank, unless particularly ordered into the front of each platoon, if a march for any considerable distance is to be made. When on the pivot flanks, they

are answerable in their own persons for distances and covering. When in front, their sergeants, under their direction, preserve the ordered distance.

In wheeling from line to column, each moves out, and places himself one pace before the centre of his platoon. Each turns towards his men during the wheel, and inclines to his pivot flank. Each gives his word, *Halt—Dress*, when his wheeling man has just completed his degree of wheel. Each squares his platoon, but without moving what was the standing flank. Each then places himself on the proper pivot flank. After the wheel into column is completed, no one is to cause his platoon to shift, by way of covering on the pivot flank, unless so ordered by the commanding officer, or that in the course of marching a straight line is gradually taken up. In wheeling from column into line, the officer places himself one pace before the centre of his platoon, turns towards his men during the wheel (inclining towards the pivot of his preceding platoon), and gives the word *Halt—Dress*, when his wheeling man, on whom his eye is fixed, is just arrived at the next standing pivot man. He then, from that pivot man correcting the interior of his platoon upon his own pivot man, takes his place, and remains steady on the right of his platoon.

If the column is in movement, and platoons are successively to wheel into a new direction, each officer, to whatever hand he is to wheel, gives the word from the point he is then placed at, whether in front or on the flank. If on the wheeling flank, he conducts it; if on the standing flank, he steps out two or three paces, the better to see that his platoon wheels quick, with a proper step, and that he may time his word *Halt*. This done he is to fall back to his place on the pivot flank, no longer to look to his platoon, but having his eye fixed on the officer of the preceding platoon, he is to give his word *March* at the instant that officer is taking the last step which establishes the proper distance between the platoons. When an officer is marching on the pivot flank, he is to be answerable for distance and covering. These circumstances alone must solely engage his attention: he can only occasionally give a glance of his eye towards his platoon, which must dress to him of course, and without any particular direction. When platoons in column are each to countermarch on its own ground, the officer, when his platoon faces, goes to that flank which is to become the pivot flank, conducts his platoon in file, and closes its leader to the sergeant, who has remained to mark the pivot, *Halts, Fronts*, and dresses it square. He then places himself where the sergeant stood.

When the battalion marches in line, officers then become individuals, equally attentive as the soldier; nor can officers then be attentive to any thing but to the correctness of their own personal march. Every operation then depends on the word from the commanding officer, who moves, halts, and dresses the battalions. Whenever the battalion is in line, officers give no commands except in firings.

When the platoons of a column file separately to a flank, the officer conducts the head; and when he arrives within thirty paces of the new position in which he is to form, he detaches his sergeant to mark the point at which he is to place his pivot front rank man, either in filing to front or rear. The officer stops at that sergeant, and halts, fronts, and dresses his platoon close to the sergeant. He then himself, after correcting his platoon, replaces the sergeant, who falls back to the rear rank. In filing, distances and dressing are taken from that hand to which, by a face of the platoons, the whole would stand fronted in column, and the line breaks into column towards the directing point. The leaders of the third, fourth, &c. platoons from the directing

flank are never to overpass the straight line which joins the heads of the first and second, but are, if any thing, to be behind it, till they arrive and halt exactly in the new line. In movements to the rear, distances and dressing are always taken from the same point to which they would be made, if the movement was to the front; that is, from the left in going to the rear, if it should be from the right in going to the front.

On the leading platoon officer of the column much of the precision of march depends. He must lead at an equal, steady pace, and on two objects either given to him, or which he himself takes up on every alteration of position. This demands his utmost attention; nor must he allow it to be diverted by looking at his platoon, the care of whose regularity depends on the other officers and non-commissioned officers belonging to it. The second platoon officer must also be shewn, and know, the points on which the first leads. He is always to keep that first officer and those points in a line; and those two officers, together with the placed mounted officers, thus become a direction for the other pivot officers to cover. In marching in open column, the covering sergeants are placed behind the second file from the pivot officers, that the officers may the more correctly see and cover each other in column. In the column of march, after the word *Halt* is given, no one is to move, and pivots particularly must remain where they are then placed. In this situation, when ordered to form, each platoon wheels up to its adjoining pivot; the whole will then perhaps, as in the case of marching upon a road, along the different turnings of a height, &c. &c. be on a winding line, and must not attempt to get into a straight line, unless so ordered by the commanding officer to answer some particular object. When the platoon wheels *backwards* from line into column, the situation and business of the officer are the same as when wheeling forwards; and he halts and dresses from his pivot flank, which he gains during the wheel.

In close column, division officers are on the pivot flanks. In forming line, before the divisions face, they are shifted to the leading flank, if necessary. The officer of each stops in his own person, when the division nearer to the forming point than himself, receives the word *Halt, Front*, allows his sergeant to proceed with the division; at the due instant gives his word *Halt, Front,—Dress*, and as soon as the front of his division is clear, the word *March*, conducting it into line. Before the division arrives within three or four paces of its ground, the officer will have stepped out nimbly to the flank of the preceding division, and will be thus ready to give the word *Halt—Dress* at the instant his inward flank man joins the preceding division. The men dress by the formed part of the line, and the officer corrects them on the known distant point. He then resumes his platoon place, which has been preserved by a sergeant. When the close column, or part of it, forms line on a rear division, the officer of each, when the one behind him halts, fronts, will step nimbly round the rear, and without impeding his division, allow his sergeant to proceed. From hence he can better judge the proper moment of giving his words *Halt, Front*, to his division. He then places himself on its inward flank, and marches up when his front is clear. The officer of one of the centre platoons is always in open column, to preserve distance for the column files. The colours wheel up into column, with the leading centre platoon, and place themselves behind the third file of men from its pivot flank. When the line forms, they close in to that flank.

When officers march in front of their divisions, they must in their own persons keep so close to the preceding ones, as not to hinder the flank of their own division from preserv-

ing its proper distance. When the head of a column of march changes its direction, and that marching in an alignment is not in question, instead of making regular wheels on fixed points, the officer who conducts the leading division will often be directed to bring it gradually round into the new direction, by the turn of the outward shoulder, making both its flanks continue moveable; but each succeeding division, without the formality of command or halt, does the same thing, the whole attention resting on each pivot flank, which at no rate must increase its distance, but during this operation preserves the same equality of time and length of step at which it was before moving. On all occasions of forming in line, either by wheeling up from open column, or in moving up from close column, or in marching up from echelon, &c. the conducting officer moves nimbly to his point of appui, some paces before the arrival of his division in the line, and from thence gives his word to *Halt*, and instantly dresses it.

Officers and serjeants of the supernumerary rank are in the rear of their respective companies. When the battalion is halted, or marching in line, they are three paces from the rear rank. In open column, they are within one pace of the rear rank. In close column, they go on the flank of their division which is not the pivot. Their great attention during movements is, that files are correct, ranks kept up, and that perfect order is preserved among the soldiers; circumstances in which they greatly assist the platoon officer, who having the more important objects of distance and the covering of pivots to observe, cannot in such situation be giving minute directions to his platoon, without losing sight of his more material duties. During the firings, the supernumerary rank, assisted by the platoon serjeants, are to keep the rear ranks well closed up to the front, and to prevent any break beginning in the rear.

The staff (adjutant excepted), in line, are three paces behind the music; in parade, at open ranks, they are on the right of the grenadier front rank. It is the particular business of the adjutant at all times to ascertain the direction on which the column is to move, or on which the formation of the line is to be made. For this purpose he is mounted; otherwise he could not properly discharge this important duty; and he can be much assisted in it, by having two or three camp colour men, or non-commissioned officers, properly trained to line themselves quickly with any two given points. He is to take care that the point where the battalion in column enters an alignment is ascertained to it; when it is moving in that alignment, that two points a-head of the column are always prepared; when it wheels up into line, that a point beyond each flank of that line is ascertained; when the line is to be prolonged, and has wheeled backward by divisions, that two points in the exact line of the pivots are ready for its march; when the close column is to form in line, that a point to each flank is given; when the battalion changes position, either by files, or by the diagonal march of divisions, that there are points given on which the pivots of files will cover, and can dress their divisions upon from their several points of appui; in short, that upon all occasions, fixed points of forming, dressing, and march, are given, except in advancing in line, where the ascertaining such points does not depend on the adjutant.

When the battalion changes position, by the echelon march, the named division wheels its eighth file into the new direction. The other divisions wheel their eighth file half the number of paces as the named one. The serjeant is on the outward flank, the officer on the inward flank of each division. At the word *March*, they move on, preserving their relative distance, and covering of pivots from before

them, and just before the inward flank of each division arrives at the outward flank of its preceding one, which is already halted in line, its officer places himself before that flank; and when his inward man touches it, he gives his word *Halt—Dress up*, if the movement is to the front, and dresses his division on the distant prepared flank point, so that his division is steadied before the arrival of the next one. When the change is made to the rear, the retiring part faces about before the division wheels are made, proceeds as above, and each officer gives the word *Halt, Front, Dress—Back*, to his division when its inward man touches the preceding formed one.

IV. *Attentions of Commanding Officers of Battalions.*

The battalion may be considered with respect to the line, what the platoon is to the battalion.

Commanding and field-officers are always to be mounted, and unless they are active on horseback, it is impossible for them to see, to correct, to prevent mistakes, or to move with that dispatch which is necessary from one point to another. Whatever operation is to be performed by the whole of the battalion at once, is done upon the word from the commanding officer, without any repetition being made by platoon officers. He puts it in motion, and halts it, whether in line or in column. He wheels it from line into column, and from column into line. He orders arms to be carried, supported, &c. He dresses it from the centre, when it has marched in line, and halts; and from what was the leading flank when it has wheeled up from column into line.

Before the column marches, the commanding officer ascertains points to the leading officer; and when he intends to change the direction of the march, he gives new points, and he watches over the just leading of the column. He takes care that all wheels of platoons are made at the identical point where the leading platoon wheeled; that all doublings of subdivisions are made successively in the same manner and at the same point; and that forming up to platoons is made at the spot where the first forming up is made; that in all diminutions of the front, the natural order of the column is preserved, whether the right or left of the battalion leads; that a column of half platoons occupies no more space than a column of whole platoons, viz. just enough to wheel up into battalion.

When the open column marching in an alignment is to form in a straight line, and for that purpose halts; the instant that it does halt, the commanding officer from the head of the battalion corrects the pivot files of men (which however ought not to be necessary) in the true line, and upon a rear point. But if the march is making in a winding direction, and that the intention is not to form, or not to take up a straight line, the platoons remain on the ground on which they halt, and do not move in any shape, until they receive a further order, either to form in line, or first to cover, and then to form or to continue the march. The commanding officer always conducts the head of his battalion column to the point at which it is to enter a new line, and he takes care in time to dispatch a mounted officer to ascertain that point. When the platoons wheel up into line, he immediately, if necessary, corrects the dressing of the battalion from the flank which led when in column, and that generally upon a point beyond the other flank.

When acting in line with others, the commanding officer of each battalion conforms to the movements of the regulating one, and from it takes, and rapidly repeats, his words of *Halt, Wheel, March, &c.*; and the least delay in repeating any of these words must undoubtedly disorder the line in proportion to that delay, for the whole of a line should march or halt at the same instant. In line, the commanding officer

officer is in the rear of the colours. From thence, by marked cautions, he makes his battalion step out, or step short, or incline, as is necessary to preserve its place in the general line. His great attention is to see and prevent the beginning of faults, and not wait till they have had their effect. By watching and regulating his advanced sergeants, he best regulates his battalion. The squareness of the march, the compactness of the files, and the equality of step, are the great objects he is to have in view. The other mounted officers are behind the wings, and can assist much in preventing faults, and in correcting them.

All the battalions of a line must halt at the same instant in consequence of that word, repeated by commanding officers, whether they are then correct, or not in line. Each half battalion from its own colour, and the men looking to it, will be immediately dressed on the colours of the next adjoining battalion. By this means a general continued line will be obtained, or, at any rate, a straight one between each two colours; and if all the colours should have truly halted in one line, the whole corps will be completely formed in a straight line. But if the halt is not justly made, and that a better line must be obtained, the colours of the defective battalions will be brought into the general line; the platoon officers will quickly arrange themselves, eyes will be ordered to the right, and the men will in an instant move up. Too much celerity cannot be used in completing this operation.

A single battalion, when it halts, is dressed on its right or left centre company, and is therefore in a straight line. Two battalions dress each from its centre on each other's colours, their outward wings conforming, and are therefore in a straight line. Three or more battalions dress from the centre of each, on their next colour; and therefore if all the colours halt in a line, the line of the whole will be straight: if they are not so halted, the general line will not be dressed, till a special correction is made, but no flank will be thrown out of the general direction. When a battalion retires and halts, it ought never to remain in that situation, but be immediately faced about, and dressed to the proper front. The greatest fault that a battalion in line can make, is increasing its interval. Bad dressing may be remedied without danger, but a false distance presents a weak part to the enemy, and is not to be closed without a hazardous movement, and great operation of the line. Commanding officers cannot take too much precaution to ascertain true points in the line in which they are to form, before the arrival of their battalions in it. When a battalion is exercising singly, a commanding officer may have two camp colour bearers behind each flank, properly trained, and ready to run out to that flank, to give points of marching, forming, or dressing upon the true line; in doing which, one flank of the battalion is generally considered as in that line, and often both.

Words of command cannot be specified for all the variety of circumstances and situations that occur, but commanding officers, being themselves clear in what is to be done, should by distinct and explicit orders, which they divide and adapt for the occasion, lead their battalions through all the points of execution with precision. This will always be found the shortest path, nor on any account should any operation, more especially the correction of an error or mistake, when once a battalion is assembled under arms, be performed in a careless or slovenly manner, which will always be the case if the commander's orders be not pointed, loud, and sufficiently explanatory.

A battalion close column forms in line on its front division, on a rear division, or on a central one, according as circumstances require; and in all cases the line formed upon is that

on which the head of the column or columns is halted before the formation begins. Therefore the division on which each battalion at any time forms, moves up at the proper instant, and halts on that line. When several close battalions, standing on the line, are to extend and form, the regulating and named battalion only can be obliged to form on a central division. Each of the others will form on its front or rear division, viz. on that which first arrives at its ground where it halts, fronts, and occupies its proper place, while the others move on, and successively come up to it. In forming line from close column, points must be given beyond both flanks in the direction of the line, and a mounted officer halts, and fronts each division, which is especially necessary for those that form upon a rear one, although less so for those that form upon a front one. The dressing and correction of the line is from the first formed division towards the other flank, and all the eyes of the battalion are of course turned to that first formed division.

The same number of points are required for the march into an alignment, and wheeling up into line of an open column of one battalion, as for that of several battalions; viz. one where the line is entered, and always two beyond the head of the column. Therefore, although these precautions may appear formal for the movements of the battalion when single, yet they are necessary in all its exercises, when it is recollected, that such battalion is in the place of, and must consider itself as the leading one of the column, on whose correct position that of every following one depends. The same exactness is required in every extension from close column into line, and in every forming and change of position that the battalion makes. In fine, in order to qualify the battalion for acting in the general line, it must at its single exercises work on points fixed and relative, and make no chance and accidental movements or formations. Although on most occasions of movement and formation, and at all times in instruction, determined points marked by detached and mounted officers are given; yet such helps cannot be expended or depended upon, when the line is advancing on an enemy, when a corps is harassed in its retreat, and when it is unsafe to send out officers, &c. In such situations every thing will depend on the eye and judgment of conducting officers, who must preserve such direction of movement, and seize such accidental points as present themselves, and lead to the object which is to be accomplished.

In whatever shape a battalion is moving, the commanding officer is never to lose sight of this great principle, that the battalion should at no time cover more ground than its proper extent when formed in line. Therefore if he is marching in line, he must take care that his files do not open; if in column, his great attention should be, that his divisions do not open. For this purpose his march must be just and compact, his wheels quick, and all doublings up, or back, which alter the extent of front, must be made so as not to impede the general movements of the column, or to change its distances. When the front is to be diminished, he must see that the doubling division slackens its pace, and when disengaged from the other division, that it inclines well up, quick, and covers, so as not to impede the division in its rear. When the front is to be increased, the moving up division does it quick, and by oblique marching.

The commanding officer must recollect, in the winding movements of the open column of march, that the wheeling distances must be just; that the pivots are to follow on the exact tract which the leading one has traced out; that the whole, when ordered, halt on the precise ground they then occupy; and that when they wheel up and form, the line will not then be a continued, but probably an irregular curved

one. But if a straight line is to be entered, and formed upon, from the point where the head enters, and not sooner, and where a mounted officer remains posted, does every platoon pivot officer begin to cover in the true line, to march in that line, and to preserve his true distance; nor must any obstacle that can possibly be surmounted, ever force the pivot officers out of that line, although the men of their platoon, when it becomes necessary, may open or widen their files from them. If the pivots, on account of any material impediment, are thrown for a time out of the line, they should always, if possible, move to the hand which carries them behind the line, and again re-enter it if they can; for which purpose an officer, or non-commissioned officer, should be placed where they are to re-enter it. In marching in the alignment, the commanding officer should frequently place himself in it, see with a glance of the eye whether his files preserve it, and correct them if necessary.

As one field officer at a time must command the battalion, the others present can only act in aid of him, nor can their situation in all cases be ascertained; but should the commanding officer not be at the head of the open column when it marches, and particularly when it halts, to correct if necessary the pivots in the general line, another field officer, or the leading officer, if no field officer is there, should instantly attend to it, that the wheeling up may not be delayed. If in the course of exercise and instruction, the commanding officer is not behind the centre when the battalion marches in line or halts, another field officer from that situation can immediately give every proper aid in movement, or in lining as it ought when halted; and in every case it must be evident in what manner the commanding officer can be assisted.

When the line is to break and wheel into open column of march, in almost all cases it is better done by wheeling backward than forward, for the wheel is in this manner made on the pivot flanks; and although divisions may be unequal, yet these flanks cover after the wheel, an advantage which is lost if the wheels be made forward. When a battalion makes a retired echelon, or part of an echelon of a considerable line, the commanding officer must take great care to regulate his movements by those of the one preceding him, viz. that he preserves his parallelism, his ordered distance, his proper flank interval, and when the leading echelons halt, and that he is to move up into line, that the outward flank is not thrown too forward (which without great attention will happen), and thereby perhaps be exposed to the enemy's enfilade.

Commanding officers of regiments, brigades, or larger bodies, are moveable according to circumstances, and should, by no means, consider the centre of such bodies as their general post in exercise or movements, or expect by the exertion of one voice, from one fixed situation, to command and direct the whole. Their presence is more frequently required near one or the other flank. In general, they should be at the conducting point of movement or formation, and to that address their orders by voice or message; for if that point is led or placed in the direction it should take, there is little danger of the other parts of the corps not properly and successively conforming to it. There are many situations in the movements of great bodies, where commands, that are not immediately to influence the whole, are not given loud, but quietly, to the directing body, to whose situation the rest by the eye conform: as when the head of an open column is ordered to halt, that the rest of the divisions may move on, and successively stop in close column; and on all occasions where parts only of a large body are to march, or halt, successively. In these cases, commanding officers of

regiments should have an attention to give their commands in such manner as not to produce an alteration in those points that are not meant to be influenced by them at that instant.

Where a large body is marching in column or columns, through a narrow ground, and when its parts are to be assembled beyond the defile in several lines, in a compact manner behind each other, such parts are not to begin to assemble when the leading one does, but the head of each line is successively first to come up to the ground on which it is to stand, and when it there halts, its proper followers, and not before, move into line with it; thus not impeding the divisions that are still behind them in the defile, and are to perform the same operation.

Precision of movement depends altogether on the instant circulation of commands of execution, and that on the attention of officers to the point they may be expected to come from. Unless the whole of a body, however large, is put in motion at the same instant, a column will be extended badly, and a line will be ill dressed, and with false intervals. Officers must particularly attend to the difference between changes of direction made by *wheel*, and by *shoulders forward*. In the first case, one flank remains fixed, while the other is on the wheel; in the second, both flanks are in motion. *Shoulders forward* applies to a small front, and to a column of march, where the change of direction is to be made gradually, without an alteration of the pace. In proportion to the front of the body so changing, must be the degree of sweep made by both flanks; and in all cases, the reverse flank conforms to the pace of the pivot flank. In no case can it be made short and quick, otherwise it becomes a wheel.

Regulations in Firing.

1. The advance of the battalion should instantly succeed the forming of the line, and when it arrives and halts at the point where it is to fire, the firing ought instantly to commence at the word *Halt*, for the battalion having been apprized, during the march, of the nature of the required firing, no improper delay need therefore be made. The greatest care should be taken by the officers and non-commissioned officers in the rear (whose principal attention this is) that the rear ranks are well locked up in the firings, and that in loading they do not fall back.

2. The pause betwixt each of the firing words *Make ready—Present—Fire*, is the same as the ordinary time, viz. the 75th part of a minute, and no other pause is to be made betwixt the words.

3. In firing wings by companies, each wing carries on its fire independent, and without regard to the other wing, whether it fires from the centre to the flanks, or from the flanks to the centre. If there are five companies in the wing, two pauses will be made betwixt the *fire* of each and the *make ready* of the succeeding one. If there are four companies in the wing, three pauses will be made in the same interval. Thus will allow sufficient time for the first company to have again loaded, and shouldered at the time the last company fires, and will establish proper intervals between each. In firing by wings, one wing will make ready the instant the other is shouldering. The commanding officer of the battalion fires the wings.

4. In firing by grand divisions, three pauses will be made betwixt the fire of each division and the *make ready* of the succeeding one. In platoon firing, two pauses will be made. In firing by subdivisions, when one *fires*, the next *presents*, when one *presents*, the next is *ready*: thus keeping up an incessant fire.

5. In firing companies by files, each company fires independently;

pendently; when the right files present, the rest make ready, and so on. After the first fire, each man as he loads comes to a recover, and the file again fires without waiting for any other. The rear rank men are to have their eyes on their front rank man, and be guided by, and present with them.

6. In general, after the march in front, and halt of the battalion, company, or platoon firing, should begin from the centre, and not from the flanks. In other cases, and in successive formations, it may begin from whatever division first arrives, and halts on the ground.

7. The line, if retiring, *Halts, fronts*, at one command, and instantly begins firing, from the centre, and not from the flanks.

Objects of Fire.

I. *Against Cavalry.* The chief object of the fire against cavalry is to keep them at a distance, and to deter them from the attack. As their movements are rapid, a reserve is always kept up. But when fire commences against infantry, it cannot, consistent with order, and other circumstances, be too heavy or too quick while it lasts, which should be till the enemy is beaten or repulsed, or till the contest becomes too unequal. The fire of three ranks standing is hardly, with our present arms, to be required, especially if the ground should be broken, and the soldiers loaded with their knapsacks. The fire of the rear rank, therefore, is generally reserved.

II. *Defensive Fire.* Where infantry are posted upon heights that are to be defended by the fire of musquetry, the front rank will kneel, that one-third of the fire that may be given should not be lost; otherwise the rear rank in such a situation could not sufficiently incline their pieces to raise the slope. As soldiers generally present too high, and as fire is of the greatest consequence to troops that are on the defensive, and who are posted if possible on commanding grounds, the habitual mode of firing should therefore be rather at a low level than a high one; and the fire of the front rank, kneeling being the most efficacious, as being the most raising, should not be dispensed with when it can be safely and usefully employed.

III. *In Line advancing.* When infantry marches in line to attack an enemy, and in advancing makes use of its fire, it is preferable to fire the two first ranks only standing, than to oblige the front rank to kneel, thus firing the whole. But volleys, fired at a considerable distance, or on a retiring enemy, may be given by the three ranks, the front one kneeling.

IV. *Platoon Firing.* A line posted, or arriving at a fixed situation, will fire by *platoons*, each battalion independent, and such firing generally commencing from the centre of each. The first fire of each battalion will be regular, and establish intervals. After the first, each platoon shall continue to fire as soon as it is loaded, independent of any other, and as quick as it can, till the battalion or line is ordered to cease.

V. *Independent, or File Firing.* If behind a parapet, hedge, or abbatis, the two first ranks only can fire, and such firing may be file firing, and may be made deliberate and cool, the two men of the same file always firing together. It may begin from the right or left of platoons, and should be taught in situations adapted to it, not in open ground. Should the parapet, hedge, or abbatis be but little raised, platoon firing may be used.

VI. *Running Fire.* Troops should be often practised in executing the *lillebande*, or running fire. This should begin on the flank files, and when once commenced, continued without the soldier being subject to any other rules than

keeping silence. This sort of firing is the only one which infantry should make use of in engagements. It is the most lively, and more slaughtering than any. It emulates and warns the soldier, and renders him insensible to danger. The grand point is to accustom troops to leave it off when a signal is given, and afterwards remain silent.

VII. *Oblique Firing.* Oblique firing by battalions is advantageous on many occasions. As when attacked in an oblique direction; when time does not allow to give an obliquity to a greater part of the line; and when their fire can in this manner be thrown against the opening of a defile, the flanks of a column, or against cavalry or infantry that direct their attack on some particular battalion or portion of the line.

VIII. *Regularity of Firing.* As long as the fire by battalion, by wings, or by platoons, can be kept up regular, it is highly advantageous, and can at any time be stopped; but should file firing be allowed, and one begun, unless troops are exceeding cool and well disciplined, it will be difficult to make it finish, and to make them advance and charge in order. When a line halts at its point of firing, no time is to be lost in scrupulous dressing, and the fire is instantly to commence; but a line that halts, and is not to fire, or when its firing ceases after the halt, may immediately be ordered to dress from colours to colours.

IX. *Street Firing.* It is so called from being obliged to engage in a street, highway, lane, or narrow passage, where no more than 10, 12, 16, or 20 files can march abreast; so that, according to the breadth of the place, the platoons must be stronger or weaker. When the column is in motion, and arrived where the firing is to begin, the commanding officer, from the rear, gives the word *Halt*. The officer commanding the platoon instantly gives the words *ready, present, fire; recover arms, outwards face, quick march*. At the word *recover arms*, the platoon immediately in the rear of the one that has fired, recover their arms also, and cock, and when their front is open by the march of the others down their flanks, they march on with recovered arms, until they receive from their officer the words *halt, present, fire, &c.* As soon as the platoon has got down the flanks, it must form instantly in the rear, and immediately prime and load again without halting, keeping always their exact distance from the division before them, which would not be the case if they halted to load and shoulder.

When this is to be put in practice on real service, the front of the platoons must not be equal to the breadth of the place they are to engage in; but there must be a small space of ground, or interval, left on the flanks, for those who have fired to have room to march back, and form in the rear. It is in this manner, when there is not time to raise a breastwork, that a pass, bridge, road, or street is to be maintained against the enemy, by the platoons sustaining one another, and firing in their turn, which may be continued as long as there is occasion, almost without intermission, by one battalion only. In firing as above described, the colours, &c. must at the first be placed in the rear, and kept there by the subdivisions, as they come down the flanks after firing, forming constantly in their front, till the whole business is over.

There are, however, different methods of retiring the platoons from the front to the rear. Some are instructed, after the word *fire*, to recover their arms, and wheel out the platoon by subdivisions from right to left, load, and remain in that position till the last platoon passes them, when they wheel back, and form. Another method is, supposing the street to be filled by the platoon, and no room left on the flanks, then by throwing back or retiring a centre section

of each platoon, the retiring division may pass through the centre of the column to the rear. It looks well, and has a good effect on a day of parade; but it is too complicated to be attempted with safety in the presence of an enemy.

General Observations.

There is no doubt but that the fire of the musquetry may be reduced to a theory; but far from that being the case, the soldier has no principle given him, for at the distance or situation of the objects, be what they may, he fires at random. It is principally owing to the exercise of the target being so little practised, that this ignorance and deficiency of principle is so severely felt.

In our firings, the soldier is instructed always to fire low, yet no reason is given him why it should be so, but that the ball rises. To consider this a moment; the line of level [The line of level is the straight line by which is seen the object on which the ball should be carried to.] and the line of fire [The line of the fire is a straight line which represents the axis of the musquet.] are by no means parallel; for according to the different weights of metal which the barrel has at its breeching, and at its aperture, so they describe an angle more or less acute beyond the tube. As the eye seeks its aim from the length of the line of level, it is therefore fixed at the exterior of the barrel. But entirely different to this principle, the motional body, the bullet, is impelled from the interior part of the instrument, and the length of the line of fire; therefore the line of fire and the line of level cut each other. From the law of attraction imposed on all bodies obliquely thrown, at its delivery from the mouth of the cylinder, the bullet or ball describes a curve, which rising from the muzzle, cuts the line of level at a small distance from the mouth of the barrel. It will, at about the distance of 60 toises, or 360 feet, be found to be at a foot and a half or two feet, its greatest elevation above the line of level. From thence drawn to the earth by that gravitation to which all bodies are subjected, it again inclines to the former line, and at the distance of about 120 toises, cuts it a second time. It is this second point of intersection which is called the musquet-shot, or point blank, after which the bullet finishes to describe its parabola to the end of its fall. What is here said is a common property to all fire-arms.

It follows, that to make the ball arrive at the mark intended, the sight must not be always precisely levelled at that mark. Suppose a mark six feet high, divided into three equal parts, if the distance from it is 50 or 60 toises, or 360 feet, then to strike the upper dimension aim must be taken at the middle one, two feet under the mark. If meant to strike the middle, aim must be taken at the lower dimension, &c.

If at 100 toises, the aim must be taken one foot below the mark in order to hit it. If the distance is more than 100 toises, to strike any of the dimensions, aim must be taken above the mark, and so keep raising in proportion to the distance.

Suppose a battalion of the enemy in front; if at 300 toises distance, aim should be taken three feet over the battalion. If at 200 toises, about a foot and a half. If at 150, aim should be taken at their hats. If at 100, at the middle of the body, &c. Although the horizontal shot of a musquet may be computed at 180 toises, yet, where the fire of a line of infantry can have effect, it is seldom more than at 80 toises, or 160 yards.

We shall close this article with some account of the form of a review of a battalion of infantry, and the method of performing the eighteen manœuvres, as practised by his majesty's forces.

Receiving the General.

At the time appointed for the review, the battalion will, as directed above, draw up in *open order*. Four camp colours are to be placed so as to form a square, round the angles of which the wheelings are to be made. A fifth camp colour is to be placed eighty or a hundred paces in front of the centre of the battalion, where the general is supposed to take his station; and a sixth at the same distance, in the rear of the battalion, and opposite to the one in the front; but although the general may choose to quit that position, still the colour is to be considered as the point to which all movements and formations are relative. The colour must be so placed, that the right flank of the divisions, when marching past in review, shall be about four yards distant from the general.

When the reviewing general is within fifty or sixty paces of the centre, he will be received with a general salute; the colonel, with his back to the regiment, gives the word *present arms*. The men present arms, and the officers salute; the music will play, and the drums beat. The officers, in saluting, take their time from the flugel man; as he comes to the *poize*, they bring their swords to the *recover*; as he sinks his firelock to the last motion of the *present*, they drop the points of their swords; when he comes to the shoulder, they bring their swords to the *recover*; and then, taking their time from the colonel, bring them gracefully across their bodies to the port, and remain perfectly steady and square to the front. The colours only salute such persons as, from their rank, and by regulation, are entitled to it.

The colonel then gives the word *shoulder arms*. While the general is going round the battalion, every person remains perfectly steady: no compliment is paid. The music will play, and the drums beat, but they will cease as soon as the general has returned to the right flank of the battalion. While the general is proceeding to place himself in the front, the colonel turns to the regiment, and gives the word *rear ranks take close order—march*. He will then, as also the lieutenant-colonel, mount on horseback, in the rear of the centre, giving the words *companies, on the left backwards wheel—quick march*. Pioneers and music are ordered to the head of the column. Officers commanding companies must be very attentive when they give the words *halt—dress*, to see that they are well obeyed.

Column—March. The companies wheel successively at the first and second angles of the ground. When the leading company has made the second wheel, it brings them on the line on which they pass the general. Each leader of a company, when it has advanced six paces from the wheeling point, changes quickly by the rear to the right flank of his company, and gives the words *eyes right*, then *rear ranks take open order*. The music begins to play, the officers move three paces in front of the company, dividing the ground equally, the captain on the right, the lieutenant on the left, and the ensign in the centre. The captain's place is supplied on the right flank by his covering sergeant, who is responsible for keeping the company at the proper wheeling distance from the one preceding it. The colonel is at the head of the grenadiers, or leading company, with the major a little behind him on his left. The music are in two ranks, six paces before the colonel. The pioneers are in two ranks, six paces before the music, having a corporal at their head to lead them. The drummers and fifers are on the left flank of their respective companies, and the supernumerary sergeants, three paces in the rear of them several divisions. The lieutenant-colonel is in the rear of the light company; the adjutant a little behind him on his left. The colours are

three paces behind the fourth battalion company, covered by their serjeants. Staff officers do not march past.

The officers, when within six paces of the general, prepare to salute, by recovering their swords. They drop them when in a line with the general, and recover them when ten paces from him, bringing them afterwards to the port, without in the least altering the rate of march, or impeding the front ranks of their companies. The commanding officer, when he has saluted at the head of the column, places himself near the general, and remains there till the rear has marched past. The drummers give a roll each, when the officers of their own companies salute. The officers commanding companies will, each successively, when he has passed the general by thirty paces, give the words *rear ranks, take close order*, and will immediately shift to the left, the proper pivot. Officers bring their swords to the advance, and each individual of the company resumes the post which he held when the column was first put in motion.

When the third wheel is completed by all the companies, and the leading company is near to where the left of the battalion stood in its original position, the colonel gives the word *halt*. The whole halt, and the music ceases. At the words *support arms—quick march*, the whole march off in quick time. No music. The column makes three several wheels; viz. at the point where the left of the battalion first stood, at the point where the first wheel was made, and just before the third wheel commences, the colonel gives the word *carry arms*.

When the third wheel is completed, which passes the column on the line of passing the general, the music begins to play. The leading officer of each company shifts to its right, by its rear, giving the word *eyes right*, and when he has passed the general thirty paces, he will resume his proper pivot flank, giving the word *eyes left*. The supernumerary officers and serjeants march in a rank, in the rear of the several companies, at one pace from the rear rank; and officers' swords are carried steadily against the right shoulder. The colonel, lieutenant-colonel, major, and adjutant, are in the same places as in marching past in ordinary time; as also drummers, pioneers, and music. In marching past in quick time, no compliment is paid by officers.

When the head of the column approaches to the left of the ground on which it originally stood, the music will cease. The colonel gives the word *halt*, and, after a pause, *march*. The men carry their arms, and the column takes up the ordinary march, for the purpose of moving on an alignment. When at the point on the left of the alignment, each officer gives the words *halt, left wheel, halt dress, march*. It is scarce necessary to observe, that these words are repeated at every wheeling point. The column prolongs the alignment, till arrived at the point where its head or right is to be placed, viz. where it originally stood. The colonel then gives the word *halt*. Pivots are corrected, if necessary, but should be done instantly, and if possible, ought to be avoided, as nothing can more clearly point out how badly disciplined, and how inattentive the commanding officers of companies must be, when this operation is necessary to be done in the face of the general. On the word, *companies, to the left, wheel into line*, pioneers and music go to their posts behind the centre, officers move to the front of their companies, and at the word *quick march*, the battalion wheels up again into line.

When the line is formed, the colonel then cautions the battalion, that it will perform the manual and platoon exercise. He immediately goes to the rear, and the major, advancing to the front of the battalion, gives the commands

rear ranks take open order, march—order arms—unfix bayonets—shoulder arms—officers take post in the rear. The officers recover their swords, and face to the right. On the word *march*, they, as well as the colours, &c. march through the several intervals occupied by the serjeants, three paces beyond the rear rank. At the word *front*, they face about, and bring their swords to the port. The colonel, lieutenant-colonel, adjutant, pioneers, music, supernumerary serjeants, drummers, and fifers, are at their posts in the rear, as when the battalion is formed at close order, where they remain perfectly steady.

The major proceeds with the manual as directed by regulation, observing only the front rank comes down to the last position of the *charge bayonet*, the others remaining ported. The serjeants who preserve in the front rank the places of the platoon officers, remain there steady during the whole of the manual, except that they charge their pikes at the same time as the bayonets. When the manual is over, the major gives the words *rear ranks take close order, march*, on which officers, serjeants, colours, and every other individual, take their places as when the battalion is at close order. The major then gives the word *platoon exercise*, and proceeds with it, according to regulation. When finished, the major goes to his post, the colonel comes into the front, and gives the word *with cartridge—prime and load*. The corps is now ready to commence the ordered movements. The flugel man stands opposite the centre of the battalion, with his front to the general, and goes through the motions as directed for the manual exercise, &c. Of course he is not to perform any of what are called the flugel motions.

Method of performing the EIGHTEEN MANOEUVRES.

FIRST MANOEUVRE. *Close Column on a Rear Division.*

The colonel gives the word *the battalion will form close column of companies, in rear of the grenadiers. Remaining companies—right, face*. All the companies, except the grenadiers, face to the right. The captains and their covering serjeants post themselves at the head of their files, ready to lead. Two or three leading files of each company disengage a little to the right. The captain of the grenadier company, with his covering serjeant, shifts to the left of his company, the pivot flank. The colonel then gives the word *quick, march*. All the companies, except the grenadiers, step off at once, and move on in file till they come near the company to be formed on, when the serjeants who were leading the files step briskly forward to mark the situation of their companies in the perpendicular of the front of the column. The covering serjeant of the first company halts one pace in the rear of the covering serjeant of the grenadier company, carefully covering him, and standing perfectly square in his own person. His own captain also halts close to him, and allows his company to move on in the rear of the serjeant, taking care that the right hand, or leading file of the company, does not pass beyond, but mark time when it comes up to the right hand file of the grenadiers. As soon, therefore, as the captain sees that the left hand file of his company is in with his covering serjeant, he instantly gives the word *halt, front, eyes left*; and having dressed his company correctly on his covering serjeant, he gives the word *eyes, front*, takes his proper post, which his serjeant had kept for him, who immediately covers him, while the captain himself correctly covers the captain and covering serjeant of the grenadier company. In this manner each succeeding company proceeds till the column is completely formed. The colours precede the fifth company, and remain on its reverse flank, covered by their serjeants.

The close column being now formed, with the right in front, the colonel gives the word, *form column of grand divisions*.

divisions. At this caution, all supernumeraries, but not the colours, go to the rear of the column, if not there already. *Left companies, left face.* The left companies immediately face, always to the pivot flank, and their captains take one side step to the right, so as to be clear of their rank. At the word *march*, the captain stands fast, the sergeants conduct the divisions, and the captain of each, when it has cleared the standing division, gives the word *halt, front, dress.* He then steps nimbly to the third file of the standing company, and from that gives the word *march, halt, dress.* The captains commanding the right companies are now on the right of each grand division. The captains commanding the left companies move to the left flanks of the grand division, their intervals being kept by their sergeants. The colonel now gives the word, *the column will close to the front, march.* All the divisions step off, except the front one, and each, when within one pace of the division in its front, gets the word *halt, dress,* from the pivot captain of each division. The close column of grand divisions is now formed, and ready to deploy. The colours are with their proper division in the column, and that division must, of course, out-flank on the hand, not the pivot. To obviate this inconvenience, some regiments leave a space between the third and fourth grand divisions, for the colours.

The colonel then gives the word, *the column will take ground to the right, and on its march deploy on the rear grand division.* At this caution, a serjeant immediately steps out from the rear division, and places himself on the pivot flank of the front grand division, following it in file. When the rear grand division is halted, this serjeant halts also, and instantly fronts, remaining perfectly steady to mark the ground for the rear grand division to march up to. The colonel gives the word *right face, quick march,* and when the column, in obedience to these orders, has marched as far as he sees necessary, generally twenty or thirty paces, he gives the word *rear grand division, halt, front,* and when he sees that the division immediately before the rear one has cleared its front, he gives the word, *fourth grand division, halt, front.* As soon as the rear division, which has halted and fronted, finds its flank free by the *halt, front,* of the division that was immediately before it, at that instant the captain on the left gives it the word *march.* The grand division marches steadily till it places its pivot flank; the left, close to the serjeant who had stepped out to mark the ground for it. It then receives the word *halt, dress,* from the captain on the left. He dresses the grand division, from the standing serjeant (the point of appui) to the camp colour (the point of formation) on the right. As soon as the dressing is finished, he shifts to the right of his company. The rear grand division being dressed, the fourth is marched up, and dressed on it, exactly as the rear one had dressed on the standing serjeant, and so the third, second, and first, till all are in line. If the deployment be correctly made, the first grand division has only to *halt, front,* as it is already in the true line. Much of the exactness of this, and every deployment of the same kind, must depend on the accuracy of the mounted officer, who halts and fronts each grand division. For this purpose he must be in the rear of the column. If he is confused, all will be deranged. Supernumerary officers and serjeants, drums, music, and pioneers, halt with their respective grand divisions, and as they are halted and dressed, take their proper stations in the rear. The line is now formed to the general's left.

Observe, when the column deploys on the rear division, it faces from the pivot flank, which then becomes the following one.

SECOND MANŒUVRE.—*Close Column on a Front Division.*

The colonel gives the word, *the battalion will form close column of companies in front of the right infantry: remaining companies—left, face.* The captains and their covering serjeants post themselves at the head of their leading files. Heads of files disengage. At the word, *quick—march,* the covering serjeant of the eighth company steps briskly forward till he comes in front of the light infantry captain, and three paces from him he faces him. Then, being certain that he is in a true line with him, he immediately faces to the right about, and stands perfectly steady, and square to his front. The captain of the eighth company leads on his company till he places his pivot man close to the serjeant. He then gives the word *halt, front, dress,* replaces his serjeant (who immediately covers him), and gives the word *eyes front.* In this manner, each succeeding company proceeds, till the column is completely formed, with the grenadiers in front. The colours move in rear of the fifth company.

The column of grand divisions is then formed, and closed up, exactly as directed in the first manœuvre.

The colonel then gives the words, *the column will take ground to the left, and on its march deploy on the front grand division, left, face—quick, march.* When the column has marched thirty or forty paces, or as many paces as the colonel sees necessary, he gives successively, and in due time, to each grand division the words *halt, front,* till all are halted, beginning with the front division. The inward captain of each grand division (that is, the captain on the right,) when it has halted and fronted, gives his words, *dress, march, halt, dress,* and the outward captain (the captain on the left) remains on the flank of the division in the line, till the succeeding captain, having so dressed his grand division, comes to replace him. He then replaces his covering serjeant on the right of his proper company. In this manner, grand division after grand division comes up till the whole are in line, and the supernumeraries also take their places gradually in the rear.

Observe.—When the column deploys on a front division, it faces to the pivot flank, which then becomes the leading one.

THIRD MANŒUVRE.—*Close Column on a central Division, facing to the Rear.*

The colonel gives the word, *the battalion will form close column on the right centre company, facing to the rear. Right centre company, right, face. Right counter-march, quick march.* The captain at the head of his company, which has faced immediately on receiving the order, turns short in file to his right hand, and leads his company till he places his front rank in line with the rear rank of the fifth and third companies. He next gives the word *halt, front,* and then *dress,* from the right of his company, where he remains. The colours and centre serjeants counter-march with this company. At the word *remaining companies, outwards, face,* the companies on the right of the right centre companies face to the right, those on the left face to the left. Captains and their covering serjeants move to the heads of files. On the word to the left counter-march—*quick march,* the captains lead the files; the whole step off at once. The companies of the left wing, No. 5, 6, 7, 8, and light infantry, file one after another in the front of the right centre company. The right wing, No. 3, 2, 1, and grenadiers, file one after another into the rear of the right centre company. The serjeants must be very careful to follow the instructions, as in the first and second manœuvre. Each company, as it compleats its counter-march, receives the word, *halt, front, dress,*

about, from its own captain, who is now on the pivot flank, the right; the left of the column being in front.

At the word *column, left face*. The column immediately faces to the left, captains, &c. moving to the heads of files to lead them. All the covering serjeants stand fast. At the word, *the left hand companies will lead out, quick march*, the left, or alternate companies, that is, No. 1, 3, 5, 7, and the light infantry, march out in quick time, until their rear has cleared the standing companies about four or five paces. The colonel then gives the command *halt, the whole will counter-march to the left, left counter-march, quick march*. The whole, except the covering serjeants, who face to the right about, instantly counter-march. The right companies, viz. the grenadiers, 2d, 4th, 6th, and 8th, counter-march on their own ground exactly. The left companies, i. e. the 1st, 3d, 5th, 7th, and light infantry, march on towards the column, until they fill the intervals they had quitted, and are again in column in their proper place. The captain of each company gives the words, *halt, front, dress*, at their companies fifth the counter-march, which is completed when the leading man of each front rank arrives at his respective serjeant. When the counter-march is finished, the column stands with its right in front, as in the first manœuvre, and its centre opposite the general.

The colonel gives the word, *the column will deploy on the right centre company, remaining companies, outwards face*. The right centre company stands fast. The companies on the right of the right centre company, face to the right; those on the left of it, face to the left. At the word *quick march*, the covering serjeant of the right centre company steps up to the left flank of the grenadiers, and remains there. As soon as the flanks of the right centre company are clear, its captain gives it the word *march*, and when he arrives close to his covering serjeant who occupies the exact ground quitted by the grenadier captain, he then, with great exactness, *halts*, and *dresses* his company on the serjeant (the point of appui) to the point of formation on the right, and then, giving the word *eyes front*, shifts to his post, the right of his company. When the remaining companies are clear of each other's flanks, they get the words *halt, front, march*, from their own captains. The third company dresses from the right of the right centre company, its point of appui, to the distant point of formation on the right. The other companies of the right wing dress in the same manner on the standing companies as they severally come up into line. When the fifth, or left centre company, has marched up to its point of appui (the left flank of the right centre company), its captain from that point dresses his company to the point of formation on the left. In this manner each company proceeds, till all are in line on their original ground, the centre opposite the general.

FOURTH MANŒUVRE.—*Change of Position in open Column.*

On the word *by companies on the left backwards, wheel*, left hand men of companies face inwards to their companies. Captains step nimbly to the front of their divisions. The serjeant of the right company steps back, and remains to mark the spot where the wheeling man of his company is to rest when the quarter circle is completed. The other companies conform to this, each standing perpendicular to the base line on which its pivot is placed. At the word *quick march*, all the companies wheel back the quarter circle on the principle already laid down. Captains *halt, dress*, their companies, and then giving the words *eyes front*, remain on the pivot flank of their companies. The battalion is now in open column of companies, the right in front.

The colonel gives the word *column march*. The column marches thirty or forty paces in ordinary time. The adjutant, having been apprized by the commanding officer, that the battalion is to change its direction to the left, and having the spot pointed out to him where the change is to commence, and also the direction which the column is to take, will immediately move forward, and place a camp colour at the spot where the leading company is to wheel. He will place a second colour as the point of direction on which the leading flank of the column is to move in the new alignment; and he will place a third camp colour, the point of formation, oblique to the right of the column, covering exactly the other two colours, so that a line drawn from the second colour to the first, and continued to the third, will be a right line, which line will be oblique to, and cut the original line on which the column was marching at the point where the leading company began its wheel, which point is on the new alignment. These matters being all quickly arranged, when the colonel sees that the leading company is near the point of wheeling, he will give the words

The column will change its direction to the left. The captain of the leading company, on the principle of the moveable pivot, gives the words *right shoulders forward*, and when the company has made the required wheel, he gives the word *forward*, and keeps his eyes fixed on the distant camp colour, to which he steadily marches. Each company as it approaches the wheeling point (the first camp colour), conforms exactly to what has been done by the leading company. When the colonel sees as many companies wheeled into the new direction as he judges to be sufficient, generally three, he gives the word *halt*. The leading companies, and such others as have already wheeled into the alignment, being now at their proper points, remain so.

The rear companies will file into the new alignment. Rear companies, right, face. At this word, all the companies who are still in the old direction face to the right, i. e. to the flank which conducts to their place in the new line. Captains and their covering serjeants shift to the heads of files, to lead them. At the word *quick march*, the serjeants step briskly forward, to mark their points in the line where the pivot flanks are to be placed. Each captain leads his company to his covering serjeant, where he halts, and lets his company pass in rear of the serjeant, till its left flank is in with him, and he then gives the word, *halt, front, dress*. At the word, *column, to the left wheel into line, quick march*, the serjeant of the grenadiers moves quickly to the right, and places himself in line with the pivots. The rest of the covering serjeants go as usual to their right flanks, to keep the place for their captains. When the wheel is completed, the captains give the word *halt, dress*, from the file on their right to the camp colour on the left, and immediately replace their covering serjeants.

FIFTH MANŒUVRE.—*Wheel thrown back.*

The colonel gives the following words of command; *the left company will wheel four paces backwards on its left. The remaining companies will go to the right about, or I wheel two paces to their right*. The covering serjeant of the left company, now on the circle, steps to the rear, and on the eighth file from the pivot marches the named number of paces, and comes to the right about, lining himself with the camp colour, placed by the adjutant on the right, to mark the new line, which is to be parallel to the original line of formation. The command is then given, *left company, four paces on the left backwards wheel, quick march*. The company's serjeant halts the company in a low tone of voice, and the captain accurately dresses it on the colour to the right. At

the word, *remaining companies, to the right about face*, they face accordingly. On that of, *two paces to the right wheel, march*, each covering serjeant steps out two wheeling paces on the circumference of the circle, and when the men wheel up to him, he halts them in a low tone of voice. The captain dresses the company. The battalion now stands in echelon, with its rear ranks in front, the captains having shifted to the inner flanks of their several companies, and their covering serjeants to the outside flanks.

The battalion will march in echelon, and form line on the left company, march. The companies march with their rear ranks in front. The captain of the company next to the formed one, gives the word *left about face forward*, and then having disengaged himself from his division, the moment his leading flank man of his (now) front rank touches the flank of the company that is already formed, he will give the word, *halt front, dress back*, on which his company fronts, and, without hurry, dresses back on him and the formed part of the line, he correcting them on the more distant given point, the camp colour on the right, which having done, he goes to his post, the right of his company. Every other captain does the same, till the line is formed. It is then parallel to its original line of formation, but more ram'd by the length of seven companies, supposing that three wheel'd into the oblique alignment. The battalion is now to the general's left. It is to be observed, that the great activity must be used by each captain in this dressing, otherwise the point of appui will not be ready for the next company, and the distant point will be obscured; whereas it must be left open and distinct, so that the direction of the line may run at the distance of one file from the given object of dressing.

To follow the plan as laid down in the rules and regulations, the battalion should now go to the right about, retire fifty or sixty paces, and then halt, front.

SIXTH MANOEUVRE.—*Counter-march, solid square, and change of position.*

On the word, *battalion, by companies on the left backwards wheel, quick march*, the battalion breaks into open column of companies, the right in front. The colonel then gives the word, *the column will change its front by the counter-march of companies to the right, companies, right face*. At this word, the whole face to the right. Each captain will immediately quit the pivot, and place himself on the right of his company, and his covering serjeant will advance to the spot which he has quitted, and face to the right about. At the word, *right counter-march, quick march*, the whole move. Each captain wheels short round to the right, and proceeds, followed by his files of men, till he has placed his pivot front rank man close to his serjeant, who remains immovable. Each captain instantly gives the words, *halt, front, dress*, to his company, so as to have it squared, and closed to the right, which is now the pivot flank. The captain replaces his serjeant, who falls back behind the rear rank. The column now stands faced to its former rear, with the left in front.

Column march. The column marches thirty or forty paces. At the word *column will close to the front*, the leading company immediately halts, and the remaining companies each halt within one pace of the company in its front. Captains must be very careful to *halt dress* their companies correctly, as this is preparatory to forming the solid square. Observe, that the column may be closed at the option of the chief, either in this manner, or by the head division continuing its march, and the rear ones being ordered to march quick into close column, and successively to resume the ordinary march.

Form solid square. All the companies composing the front half of the column, i. e. the left wing, take one pace forward, except the light infantry, which stands fast. The two last companies close up one and two paces to the company before them. At the word, *subdivisions, one pace to the right and left, march*, the whole companies make an interval of two paces in the centre, by their subdivisions taking each one pace to the flanks. Two captains, with their serjeants, place themselves on each of the front and rear intervals. Two captains, with their serjeants, also take post in each of the increased intervals in the centre of the sides. A serjeant takes the place of each flank front rank man of the first division, and of each flank rear rank man of the last division. All the other officers, serjeants, the four displaced men, drummers, &c. assemble behind the centre of the companies which are to form the flank faces.

N. B. The remainder of this manœuvre cannot be correctly performed, unless each company consists of at least twelve files, formed three deep.

Four files, outwards, fire. The two rear companies face to the right about, and four files on each flank of all the companies, except the grenadiers and light infantry, face outwards, the whole lining with the flanks of the front companies, and dressing in ranks from front to rear. On the word *quick march*, the fifth file from each flank of all the companies, except the first and last, followed by the front rank man of the sixth file, move up to right and left, and respectively fill up the interval between their own and the preceding division. The remainder of the men of the side divisions arrange themselves to their right and left, forming close in the rear of their own divisions respectively. The whole thus stand faced outwards, and formed at least four deep, with two officers and their serjeants in the middle of each face to command. The captains may fill the intervals as follows: The grenadier and first company in the rear face; the light infantry and eighth company in the front face; second and third in the right face; fourth and fifth in the left face; each covered by his serjeant. All the other officers, as well as serjeants, displaced men, the colours, &c. are in the void space in the centre behind their companies; and the files of the captains in the faces may be completed by serjeants, &c. from the interior, in such manner as the chief may direct. The mounted officers pass into the centre of the square by the rear face. Whatever is the strength of the companies which compose the flank sides, the whole of them will face outwards, except their four centre files, which are always reserved for filling up the intervals.

Prepare for firing. The two first ranks all round kneel, and slope their bayonets. The two next ranks fire standing, and the others, if any, remain in reserve. The file covers behind each captain in the faces give back, and enable the captains to stand in the third rank. They are replaced by their serjeants, who, with the serjeants in the angle, slope forward their pikes, at the same time that the men slope their bayonets. The colonel then gives the word *commence independent firing*, and, on the close of the preparative, the two standing ranks commence file firing from the right of each face. This ceases on the beat of the general, and the colonel gives the word, *loading ranks, present, fire*. If ordered, the kneeling ranks may load again without rising up. Otherwise they immediately recover their feet after firing, and the word *prime and load* is given.

When the colonel sees it proper to reduce the square, he gives the words *form close column*. The files that faced outward, come to their proper front. Those in the intervals, i. e. the fifth file, and front rank man of the sixth, face about. At the word *quick march*, the front company takes

one pace forward, and the two rear companies, i. e. the grenadiers and first company, one and two paces forward, and then face about. The files from the intervals take their proper places. Officers, serjeants, displaced men, &c. will quit the interior, move to their several stations, and the companies that composed the flank faces will be complicated. Not to multiply words of command, the best method to close the subdivisions, &c. is to move the column immediately, by giving the word, *column, march*, either in quick or ordinary time, as the colonel thinks proper.

When the column has marched as far as the commanding officer judges necessary, he gives the words, *column will open from the rear*, on which the captain commanding the rear company gives the word to his company, *grenadiers, halt*, and immediately the caution *first company*, to the company in his front. When he sees it exactly at a proper wheeling distance from him, he gives it the word *halt*. The captain of the first company, when he has halted, gives the same caution and command to the second; the second to the third, and so on in succession, till the column is opened out.

The colonel now gives the word, *the column will change its head by the counter-march of companies from the rear. Right wing, to the front*. The grenadier captain gives the words, *grenadiers, left face*. He and his covering serjeant immediately shift to the left to lead the files. He then gives the word *quick march*, till his right flank can freely pass near the left flank of the others. He then gives the word, *halt, front, march* (in ordinary time) close by the left flank of the first company. The captain of that company, while the other is approaching, gives the word, *left face*; and as soon as the grenadiers have cleared his flank, *quick march*, leading his company into the rear of the now leading one. He gives the word *halt, front*, when he covers, and *march*, when at the due wheeling distance. All the other companies successively perform the same operation; and when the light company has taken its place in the rear, the whole column is in perfect order.

Column, halt, left wheel into line, quick, march. When the battalion has wheeled into line, it is considerably to the general's right, and with its rear to him. Observe, That some regiments at review, in this counter-march from the rear to the front, face their companies to the right, and bring them out on that side, contrary to the general principle. The divisions which advance come out always on the side to which front is to be made, and on which the enemy is placed; because then, with the divisions that are free, he can be opposed, while the others are moving behind the line.

SEVENTH MANOEUVRE.—Counter-march by Files on the Centre of the Battalion.

This brings back the battalion to its original front. The colonel gives the following words: *the battalion will counter-march from its centre, and on its centre, by files—wings—inwards—face*. The whole face to the colours, which stand fast; and a serjeant remains to mark each flank of the battalion. The word is given, *wings—three side steps to the right—march*; if the battalion is only two deep, two paces to the right is sufficient. Each wing takes the named number of paces to its flank, that they may be disengaged from each other. At the second word *march*, or *quick march*, the whole move on, and each file wheels successively into the centre, as it arrives at and beyond the colours. As soon as each company is in the line from the colour to the flank serjeant, the captain fronts it. When the whole is formed, the colours counter-march, and if necessary, the dressing of the line is corrected.

EIGHTH MANOEUVRE.—March in open Column.

The battalion will form open column in rear of the left company—Remaining companies on the right backwards wheel—quick march. All the companies wheel backwards on their right, except the light infantry, which stands fast. On the word *left face*, they all face to the left, except the light company; and the captains place themselves to lead the files. At the word *quick march*, the whole will lead to the rear, and the covering serjeants will successively, as before, take up their points on the new line. The captain conducting each platoon, when he arrives at his serjeant, will stop directly before him, allow his platoon to move on behind the serjeant, till the rear file comes close to, but beyond him. The captain will then *halt, front*, and *dress* his platoon, with his front rank closed in to the serjeant. He will himself take the place of the serjeant, and remain steady on the pivot flank.

As soon as the third company has taken its place in the column, the colonel gives the word *march*. The head of the column moves on in ordinary time, and the remaining companies follow, preserving the proper wheeling distance between each. When the leading company arrives within 12 or 15 paces of the point where it is necessary to diminish its front, the colonel will give a loud caution, that the subdivisions are to double, either by companies successively, or the whole battalion at once. If at once, as is ordered in this manoeuvre, then he gives the words *form column of subdivisions—right subdivisions—mark time*. Each right hand subdivision marks time, till its left hand subdivision, which marches on steadily, has opened or cleared its flank. At the words *quick oblique* or *left oblique*, the right divisions immediately oblique to the left, and cover the left ones correctly. The captains move to the right flank of the left subdivisions. Their covering serjeants lead the right subdivisions.

When the column of subdivisions has marched as many paces as the colonel sees proper, he gives the word *form companies, right subdivisions—quick oblique*. As soon as each right subdivision has cleared the right flanks of the left, by the quick oblique, it immediately receives the word *forward*, and when in line with the left subdivision, each receives the word *ordinary* from the captain, who had shifted to its right. It may be observed, that the above is in conformity to the general rule, whether the column be halted or in motion, that the subdivision or section on the reverse flank is the one behind which the other subdivision or section doubles. But in this case, were the left subdivisions to double in front of the right ones, the pivots would be better dressed, as the right subdivisions, which were marching correctly in the alignment, would not be discomposed. The colonel gives the words *column halt—right wheel into line—quick march*.

NINTH MANOEUVRE.—Echelon Change of Position.

The colonel gives the words, *companies on the right backwards wheel—quick march*. The battalion breaks into open column, the left in front, each company getting the *halt—dress* from its own captain, as usual. The colonel continues: *The seventh company* (the third, reckoning from the left) *will wheel four paces, the remaining companies six paces, on the left backwards—quick march*. The companies are dressed by their captains, who are now on the inside flanks of the echelon. The colonel orders *eighth and light company right about face*. Two camp columns are sent to the right and left in a correct line with the seventh company. At the word *the column will march in echelon, and form line on the seventh company—march*, the captain of the seventh company shifts to its right flank. Each company on the right of the seventh, viz. Nos. 6, 5, 4, 3, 2, 1, and grenadiers, as it comes successively into line, receives from its captain the word *halt—dress*

—*dress* on the camp colour to the right. The captain then shifts to the right of his company. The companies on the left of the seventh, viz. N^o 8. and the light infantry, receive the words from their captains *halt, front, dress up*. They are dressed on the camp colour to the left.

FIFTH MANOEUVRE.—*Echelon Change of Position.*

The colonel gives the words *the light infantry will wheel four paces, the remaining companies two paces to the left*. When the covering sergeants have taken the named number of paces from the front of the eighth file from the left of their companies, the colonel gives the word *quick—march*. The captain commanding the light infantry immediately shifts to its left flank. When the company has wheeled up, he gives the word *halt, dress*, dressing it correctly on the camp colour, which the adjutant had previously sent to the right for this purpose. The captain, when his company is correctly dressed, gives the word *eyes front*, and resumes his place on the right of his company, taking care that his men stand perfectly steady, and with carried arms, until the next company has dressed on them; his right flank being the point of appui. When the colonel sees that every division is ready, he gives the words *the battalion will march in echelon, and form line on the left company—march*. All the companies march in ordinary time. As they arrive in line successively, they are dressed by their captains from the standing companies to the camp colour on the right. Each captain, when he has so dressed his company, gives the word *eyes front*, and then shifts to the right of his division. The whole are now formed in line, parallel to their original front, and considerably to the general's right.

ELEVENTH MANOEUVRE.—*Change of Position.*

The colonel gives the words *the battalion will form open column of companies in the march—right face—march*. When the battalion has marched in file as far as is judged necessary, he gives the word *form companies*. The files instantly make a half face, each marching up quick and diagonally to their respective leading men, who do not alter their pace. As the pivots are in the rear of companies, when they come up, the companies dress to them by their captain giving the word *eyes left*; and they take up as they form, the ordinary step. The column marches; and when the colours are opposite to the general, the colonel gives the word *halt*, and then *to the left wheel into line, quick march*.

TWELFTH MANOEUVRE.—*Retreat in Line.*

The colonel gives the word *the battalion will retire—right about face—march*. It marches fifty or sixty paces in ordinary time, dressing by its centre. No music plays during the retreat of the battalion. The colonel gives the word *halt front*, and directly after *the battalion will fire twice by companies, from centre to flanks*. On the last stroke of the preparative, the captains on the right of companies step out one pace, and give the word of command *platoon, ready—present—fire—load*. When the first part of the general is beat, the captain falls back into the front rank. The colonel then gives the word, *the battalion will retire by alternate companies—right companies, right about face—march*. After marching in ordinary time about fifty paces, they receive the word *halt, front*. In marching, one colour remains on the flank of its proper company in each line. The king's colour with the right centre, and the other colour with the left centre company. A serjeant will advance six paces before each colour during the march. Each line directs its movements by its colour; distances are preserved from that colour, and to it the men's eyes are turned during the march. Each line has a commander. Captains are ordered to be on the inward flanks of their companies, but

this makes a perpetual shifting of positions, and is better omitted.

The colonel gives the word *left companies, make ready—present—fire*. Immediately after firing, the men come to the recover, half crouch, and shoulder arms. At the word *right about face—march*, the left companies march steadily on, dressing by their colour. They pass through the intervals of the right companies, and continue marching until they receive the word from the colonel, *halt front—prime and load*. If the chief fires the left companies, the next in command fires the right companies, exactly as the left companies were fired. They retire in the same manner through the intervals of the left companies. The colonel then fires the left companies, and retires them as before, and so on till he thinks it expedient to form line.

The left companies will form line on the right companies—march. When they have marched and filled up the intervals, the word *halt* is given by the colonel, and *dress* by the captain of each company. The right companies may form line on the left in the same manner. Sometimes the right companies are fired in battalion previous to their retiring. The words of command are the same as if they had been separated from the left companies. The light infantry may be divided in the intervals of the first line, retire with it, and charge to the other line, whenever it becomes the advanced one. In this situation, they cover the retreat, and may occasionally fire; and when the line is formed, they resume their post on the left. Unless, however, the battalion is very strong, the light infantry remain in their usual position as a company. When the line is formed, the colonel gives the word *the battalion will retire in line—right about face—march*. When it has retired as far as he chuses, he gives the word *halt, front*.

THIRTEENTH MANOEUVRE.—*March to a Flank in Echelon.*

The colonel gives the word *battalion, by companies four paces to the right wheel, and form echelon*. Covering sergeants take the named number of paces as usual. The pivots make a half face to the right, the sergeants dressing by them. On the word *quick march*, captains on the right of their companies give the word *halt, dress*. Covering sergeants go to the reverse flank. The colonel then gives the word *the battalion will advance in echelon—march*. The whole advance to the flank in echelon about two hundred and fifty paces. At the word *wheel back into line*, the three centre sergeants instantly step out into the front, and mark the time for the battalion. The pivots mark time, gradually turning to their proper front, while the rest of the divisions wheel back the four paces they had advanced. When the fourth pace is completed, the colonel gives the word *forward*; and the whole, dressing by the centre, step out their full pace, till they receive the word *halt*. The line is then considerably to the general's left, and parallel to its original front. In this situation, the colonel commands *fire three rounds by companies from centre to flanks*. Each captain gives the words *platoon, ready, present, fire, load*.

FOURTEENTH MANOEUVRE.—*The Hollow Square, and its Movements.*

The colonel gives the word *the battalion will form a hollow square on the three centre companies (viz. the fourth, fifth, and sixth), remaining companies—four paces on the right and left backwards wheel—quick march*. The companies on the right each wheel back the eighth of the circle on their left, and the companies on the left wheel the same number of paces backward on the right. The colours, at the same time that the companies are forming their echellons, move back three paces into the rear. The fourth company by the side

step inclines to the fifth company, to close the interval that was made by the falling back of the colours. At the word *right about face*, the companies that were in echelon face accordingly. The colonel then gives the word, *in echelon, march to form square—march*. Two serjeants or camp colours should be placed in the rear, in a perpendicular line with the outside flanks of the front face, marking out a perfect square. The companies now march in echelon, and by the turning of the left shoulders of the right companies, and the right shoulders of the left companies, they wheel in to form square. Their captains halt and front them in a correct line. The first company will wheel round the serjeant placed to mark the angle, and the grenadiers round the proper right of the first company; the light infantry at the same time wheeling round the serjeant on the opposite angle, till its right flank touches that of the grenadiers. They then, as also the first company, get the words *halt, front, dress*, from their captains. They have then formed the rear face of the square, and in this manner the proper front rank of the rear face will be outward. The square is now perfectly formed, and composed of four faces. The front face consists of the fourth, fifth, and sixth companies; the right face of the third and second; the left face of the seventh and eighth; and the rear face of the first company, the grenadiers, and light infantry. The mounted officers, colours, music, drummers, &c. and the battalion guns, are all within the square.

The colonel then gives the words *the square will march by the right angle of the front face, left and rear faces—right about face*. The two sides that form the right angle, that is, the front face and the right face, stand fast; the other two sides, viz. the left face and the rear face, go to the right about. At the word by *subdivisions four paces to the right and left wheel—march*, the whole by subdivisions wheel up one eighth of the circle, two sides to the right and two sides to the left, and are thus parallel to each other, and perpendicular to the direction in which they are to move. The pivot flanks are in this manner placed on the sides of the square, each side being thus in echelon, and the colours behind the leading angle. At the word *march*, captains, who are on the inward flank of their leading subdivisions, carefully preserve the distances they wheeled at, and from the flanks to which they wheeled. At the words *halt, front square, or reform square*, the whole wheel back into square; and the two sides that require it, that is, the left and rear faces, go to the right about. Captains dress their divisions as usual, in the same manner as is described for the square. The directions given for the march of the square by the right angle of the front face, will equally apply, should it be found necessary to march the square by any of its other angles.

The colonel then gives the words *the square will march by the right face*. The colours move up behind the centre of the named face, as do the mounted officers, &c. At the word *front and rear faces, by subdivisions to the right and left wheel—quick march*, the opposite side, that is, the left face, faces about; and the two flank sides wheel up by subdivisions, so as to stand each in open column. At the word by *right face—march*, the square marches two sides in line and by their centre, and two sides in open column, which cover and dress to their inward flanks on which they wheeled up, carefully preserving their distances. The same directions that are given for marching by the right face, will apply to the march by any of the other faces. The colonel, when the square has marched as far as he sees necessary, gives the word *halt, reform square*. The square halts, the subdivisions in column immediately wheel back, and form

their sides, and the side which faced about again faces outward. The captains give the words *halt, dress*.

On the word *prepare for firing*, the front rank kneel and present their bayonets sloped. The square is then ordered to fire in whatever manner may be judged proper; the two rear ranks to fire standing; or companies by ranks successively; or by companies independent of each other; or by subdivisions, one firing when the other has loaded; or companies by files; as ordered. The front rank remains as a reserve. Should the battalion be formed only two deep, the front rank will remain kneeling, and the other rank will fire by files. The word is now given *square will fire by companies, beginning on the right*. When the firing by companies has ceased, the command is given by the colonel *kneeling ranks, make ready, present, fire* (the men rise up after firing), *prime and load*. The word is then given *the square will form line on the three centre companies—side and rear faces—by companies, six paces to the right and left wheel, quick march*. The captains, as usual *halt—dress* their companies. The words are then given *in echelon march and form line, march*. The whole march in echelon, except the three centre companies, the outward companies taking care not to impede the inner ones, which must form before them. This may be done by the facing and filing of each division from its inward flank to its point in the new line, where it will form up. Captains *halt—dress* their companies, as in the third manoeuvre.

If the square is composed of the eight battalion companies only, then the grenadier and light company may be placed as a reserve in the rear, ready to be applied according to circumstances. In marching the square by any of its faces, some regiments have been instructed to march two sides in file instead of open column; and if the men march tolerably in file, there can be no question but that it is the best method.

FIFTEENTH MANOEUVRE.—*Retiring and filing to the Rear*.

When the battalion is to retire, it ought to be previously dressed with the same exactness as when it is to advance, and the same care in ascertaining the direction of its march must be taken. Therefore, before the retreat is to begin, an officer or serjeant will have placed himself thirty paces in the rear, so as to stand perpendicular to the front directing serjeant; and of course he will be in the line, or nearly so, of the directing serjeant. Whenever the battalion marches to the rear, it must cover its proper extent of ground. The rear must therefore avoid closing their files more than usual; otherwise the front rank men, who are in general larger, will be crowded in their rank. Music, drums, supernumerary officers, &c. will take care march with exactness, and not to interrupt, but rather assist the battalion.

The colonel gives the word *the battalion will retire*. As soon as this caution is given, the three directing serjeants face about. The same centre serjeant that directs to the front, directs also to the rear. He moves on in the line of the advanced officer, six paces beyond the rear rank, and halts. The two other serjeants move up on each side of him. When the line is retiring, music is never to play. On the word *right about face*, the whole face; and the supernumerary officer, who had replaced the directing serjeant, moves up into the leading rank. A mounted field officer passes through to the rear, and the directing serjeant in the interior prolongs his line, and takes his object betwixt the feet of the posted officer. Immediately after facing about, the word *march* is given by the colonel. The whole battalion instantly steps off. The replacing officer betwixt the colours preserves, during the movement, his exact distance

of six paces from the advanced serjeant, and is the guide of the battalion, the directing serjeant conducting on his points under the correction of the colonel, who is ten or twelve paces behind the centre of the battalion. In this retreat, if the light infantry act separate, and not as a company of the battalion, at the word *march* they move quickly round by the flanks, and form in the rear of the centre, extending so as to cover it during the retreat, and following at the distance of fifty or sixty paces.

The colonel gives the words *the battalion will, from the proper right of companies, file to the rear—pass companies by files*. Each captain instantly gives the word *left, turn—quick march*, and wheels out his leading file, the rest of the files following in succession. The heads of companies must observe the proper distance from each other, and are regulated from the left. Circumstances may require that the companies should pass from their proper left, instead of the right, in which case the leaders will shift and conduct such left until the line is formed, when they will again resume their proper places. When the companies in file have marched as far as is necessary, the colonel gives the word *halt, front*. The whole now stand in open column of companies, the right in front. When the column is ordered to halt, the light infantry pass quickly through it, and take post thirty paces in the rear of the intended line. On the word *by companies, left, wheel into line—quick march*, captains, as usual, *halt, dress* their companies. When the line is formed, its centre is opposite to the general.

SIXTEENTH MANCEUVRE.—*Filing, advancing, and charging to the Front*.

The colonel, having previously placed himself ten or twelve paces behind the exact line of the directing serjeant, will remark the line of its prolongation, and thus ascertain the direction in which it should march, and in doing this, he will not at once look out for a distant object, but will hit on it by prolonging the line, from the person of the directing serjeant to the front. Or he will order the covering serjeant to run out twenty paces, and will place him in the line in which he thinks the battalion ought to advance. The directing serjeant then takes his direction along the line which passes from himself, betwixt the heels of the advanced serjeant, and remarking his object, preserves such line in advancing. The colonel then gives the words *the battalion will advance*. Before the line so advances, the light company quickly forms, in extended order, thirty paces before the centre, and preserves that distance in advancing. The front directing serjeant of the battalion moves six accurate and exact paces in ordinary time, and halts. The two other serjeants that were behind him, move up on each side of him, and an officer from the rear replaces in the front rank the leading serjeant. The centre serjeant, in moving out, marches and halts on his own observed point, and the two other serjeants dress and square themselves exactly by him. The directing serjeant, after being assured that he himself is perfectly and squarely placed in the rank, by casting his eyes down the centre of his body, from the junction of his two heels, and by repeated trials to take up or prolong a line perpendicular to himself and to the battalion, will observe and take up any accidental small spot on the ground, and within 100 or 150 paces, intermediate ones cannot be wanting, nor the renewal of such as he afterwards successively approaches to in his march. In this manner he is prepared, under the future correction of the colonel from behind, to conduct the march.

The line of direction being thus ascertained, the colonel gives the word *march*. The whole instantly step off, and without turning the head, eyes are glanced towards the

colours in the front rank. The replacing officer betwixt the colours preserves, during the movement, his exact distance of six paces from the advanced serjeant, and is the guide of the battalion. The centre advanced serjeant is answerable for the direction, and the equal cadence or length of step. To these objects he alone attends, while the other two, scrupulously conforming to his position, maintain their parallelism to the front of the battalion, and thereby present an object to which it ought to move square. They are to allow no other consideration to attract their attention, and will notice and conform to the direction of the commander only. If any small alteration in their position is ordered, it must be gradually and coolly made. When the battalion is advancing in line for any considerable distance, the music may be allowed at intervals to play for a few seconds only, and the drums in two divisions to roll; but it is the wind instruments only which play. The large drum, or any other instrument whatever, which marks time by the stroke, is not permitted.

When the battalion advances fifty paces, the colonel gives the words *the battalion will file from the right of companies—pass files to the front*. Each captain immediately gives the word *right, turn—quick, march*, wheels out his leading file, and passes on direct to the front, preserving a relative distance from the left, as being the head of the column, or from the other flank, if particularly so ordered. When the column has marched fifty paces, the colonel gives the words *left, front*. The whole now stands in open column, the left in front.

The light company passes quick to the rear, assembles half of it behind each flank, and moves relatively with the flank companies.

The words now given in succession are *column, right, wheel into line, quick, march*. *The battalion will advance—march*. The battalion marches fifty paces. *The battalion will advance by alternate wings, and fire four times—Left wing, halt*. The left wing halts, and the right wing continues to move on fifteen paces. *Left wing, march. Right wing, halt, ready, present, fire, load, march*. The left wing marches past them till the right wing, being loaded and shouldered, receives the order to march. *Left wing—halt, ready, &c.* as directed for the right wing, and thus they alternately proceed, till each wing has fired twice. *The left wing will form line on the right—right wing, halt*. When the line is formed, *the battalion will advance, march*. After marching fifty paces, *halt. The battalion will fire a volley—front rank kneeling, make ready, present, fire, prime and load. The battalion will advance—march*. When it has advanced twenty paces, it receives the command *halt. The battalion will fire a volley, and port arms*; when the battalion has fired, it immediately ports arms. *Quick march*; the battalion advances firm, dressing by the centre. When it has advanced fifty paces, *halt*; the front rank comes down to the charging position. *Shoulder arms—prime and load*. The light company, issuing from behind the flanks, pursue, return, and assemble and join on the left of the battalion. The battalion is now advanced near the general, and with its centre opposite him.

If the battalion is not very strong, the light infantry should not act as such, but only as a company in battalion. In firing by wings, that is, by half battalions, the colonel generally fires the right wing, and the next in command the left. When the battalion has charged bayonets, they may be ordered to move forward on the charge at a very quick step; but by no means to run. A very few paces only can be necessary. Care must be taken that the battalion moves in perfect dress, which it cannot do if it run. The flugel man gives the time for each wing to cast about, and shoulder.

SEVENTEENTH MANŒUVRE.—Retiring in Line.

The colonel gives the words *the battalion will retire—right about, face—march*. While it is retiring, he gives the caution *the battalion will fire twice by alternate wings—the two first ranks standing*. He then gives the words *right wing—halt, front*. The light infantry are not ordered by the rules and regulations for the infantry formation, to cover the regiment in this manœuvre; but it appearing to be as requisite as in advancing, they will be formed separately. On the halt of the right wing, they file round the left flank, and cover the left wing at six paces in front, firing and retiring till they occupy the ground quitted by the left wing, dressing by the right. When the left wing has gained fifteen paces, it receives the word from the lieutenant-colonel, *halt, front*. The light infantry cease firing. The colonel orders *right wing—ready, present, fire* (the men after firing immediately come to the port, or to the recover, as may be ordered). The light infantry face to the right, and cover the right wing at six paces. On the words *right about, face—march*, the left infantry fire retiring, till they come into line with the left wing by which they dress, and continue firing. When the right wing has marched fifteen paces beyond the left, it receives the words *halt, front—prime and load*. When loaded, the signal sounds for the light infantry to cease firing. The instant the lieutenant-colonel sees that the right wing has fronted, he immediately gives the word of command, and conforms in every particular to what the right wing has done. The light infantry face to the left, and cover the left wing as they did the right, dressing by the right. In this manner each wing alternately proceeds, every due dispatch being made in reloading. When the wings have each fired twice, the colonel gives the words *the left wing will form line on the right wing—march—halt, front—prime and load*. When loaded, the light infantry ceases firing, and the signal is given by the bugle for it to form company in the rear of the centre. The colonel gives the word *the line will retire*; and when it has marched a hundred paces or more, covered by the light infantry, who file round the flanks, *halt, front*. The light infantry, upon signal, form company in the rear of the centre and afterwards resume their post on the left of the battalion.

In retiring by alternate wings, one colour remains on the inward flank of each half battalion, to which the men continue to look when they move, by which they dress, and before which a directing serjeant advances six paces. The *make ready—present—fire* of the advanced wing is instantly to succeed the *march* of the other advancing wing or the *halt, front*, of the retiring one. In the half battalion firing, advancing, and retreating, if formed two deep, both ranks will fire standing. If formed three deep, the front and centre ranks will fire standing, and the rear rank will remain shouldered in reserve.

EIGHTEENTH MANŒUVRE.—Advancing in Line.

The colonel gives the word *the battalion will advance—march*. It marches a hundred paces, and receives the *halt*. At the words *fire a volley obliquely to the right*, the men of the front rank turn one-eighth of a circle to the right; those of the rear ranks take a pace to the left, and cover their proper file leaders. The words are then given *make ready, present, fire, load*. *Fire a volley obliquely to the left—make ready, present, fire, load* (the ranks execute the reverse of what is directed in the firing to the right). *The battalion will advance—march*. When it has advanced a hundred paces, *halt*. *Fire two volleys to the front—after the last, the men will port arms, and half cock*. *Battalion—ready, present, fire, load*. *Battalion—ready, present, fire*—the men will port arms, and half cock. *Shoulder arms—shoot pans—rear ranks, take open*

order—march. The colonel and lieutenant-colonel now dismount, and come through the centre into the front, as do the music. Every one takes his station exactly as they had been placed when receiving the general. The colonel, with his back to the regiment, gives the words *the battalion will advance—march*. The music plays, and when the line has advanced within fifty paces of the general, the colonel gives the word *halt—general salute—present arms*. The music plays God save the King, and the drummers beat a march. When the music ceases, the colonel, turning the battalion, gives the words *shoulder arms—rear ranks, take close order—march*, and the review is ended.

Light Infantry. The following is the method usually observed by the light infantry when required to form in extended order, as commenced at the twelfth manœuvre. Previous to the retreat in line, the colonel directs the horn to sound the signal for their forming company, when the officer commanding it gives the words *right face—quick march* (in double quick time, to ten paces in the rear of the supernumerary rank, its centre covering the colours)—*halt, front—order arms—unfix bayonets—form two deep* (the left subdivision of the rear rank steps back one pace) *rear rank, to the left face—quick march* (its left subdivision arrives between it and the centre rank, when the whole moves forward)—*halt, front, dress*. is then given by the senior supernumerary officer. The light infantry being divided into subdivisions, the right is commanded by the captain, and led by his covering serjeant; the left by the senior lieutenant, and led by the second serjeant; the second lieutenant attends the right subdivision. On the retreat of the line, at signal from the horn, the subdivisions face outward, and file, in quickest time, round the flanks of the line, forming (when the retreat is made by alternate companies) at ten paces in front. The right subdivision covering at equal distances the right wing, except the grenadiers, and the other the left wing in the same manner, dressing to the centre. When the word *march* is given to the line, the light company, at the sound of the bugle, commence firing for the first round from centre to flanks. Each man, when he has fired, retires the ordered number of paces, generally four, by the left of his file comrade, and reloads. On the fronting of the battalion, they form company, as before mentioned, round the flanks, in rear of the line, where they divide into sections. The two sections of the right subdivision form in rear of the first and third companies: those of the left in the rear of the fifth and seventh. All the sections are faced to the left, and on the retreat of the alternate companies, suppose the left move instantly into the intervals, and form as much extended as is necessary, in line with the right companies, who still remain stationary, firing independently till the companies in line receive the order to make ready. When the right companies retreat, the light infantry move to the right, cover them as they had before done the left, and fire retiring till they arrive at the intervals between the left companies, upon whom they dress. Thus they alternately continue to occupy the intervals, till the line being formed, they wheel round the respective flanks, form subdivisions in rear of the second and seventh companies, form again in front on the retreat of the whole line, in extended order, and at its halt, assemble again in company behind the centre. In advancing in line, and by wings, the movements are similar to those already explained in the seventeenth manœuvre, with this difference, that the company moves forward instead of retiring. To re-form three deep, when re-assembled in company behind the centre of the line, the officer gives the words *form three deep* (the third section, or the whole of the proper rear rank, steps back one pace) *rear rank, to the right face—quick march* (the

rear rank of the section marks time till the front rank has passed it, and then moves on) at the word *halt, front*, they cover the centre rank correctly, at one pace distant from it. The company then fixes bayonets, faces to the left and retains its proper position in line.

Observations.

The number of paces mentioned in the several movements are not positively prescribed, but are supposed to be nearly such as will give the intended relative situations. If the ground allows the marches to the rear and front to be longer, it will be so much the better.

The colonel should give all his commands from the rear of the battalion. No commanding officer should attempt, in the face of the general, to put the regiment through any of the manoeuvres without being himself perfectly and minutely acquainted with the principles on which each is performed. He will thus avoid the disgrace of calling to his adjutant for instruction, or galloping full speed to the flank of the battalion by way of rectifying a mistake which his ignorance and temerity has brought him into, and which he cannot remedy but by recurring for advice either to the other mounted officers, or to the serjeant-major in the rear.

When the reviewing general has seen the battalion go through such of the ordered manoeuvres as he judges necessary, he will, that he may be able to report on the merits of its performance, among other circumstances, particularly observe and specify, whether or not the original formation of the battalion is according to order.

The marches are made with accuracy, at the required time and length of step, and on such objects as are given. The proper distances in column and echelon are at all times preserved. The wheelings are made just, and in the manner prescribed. The formations in line are made true, without false openings, or necessity of correction. The officers are alert in their changes of situation, exact in their own personal movements, and loud, decided, and pointed in their words of command. The march in line is uniformly steady, without floating, opening, or closing. The march in file close, firm, and without lengthening out. The officers, and supernumeraries give the aids required of them with due quickness and precision. Hurry and unnecessary delay in the movements, are equally to be avoided. In the firings, the loading is quick, the levelling just, the officers animated and exact in their commands.

Form of sending for, and lodging the colours. The battalion being in line, the commanding officer orders the grenadier drummers to beat the drummer's call; on which the two youngest ensigns recover their swords, face to the right, and march between the line of officers and the front rank, till they come to the head of the grenadiers, where they halt, front, and bring their swords to the port. The drum-major, with a party of drummers and fifers, will likewise face to the right, and march to the head of the grenadiers, placing themselves between the ensigns and the front rank. The grenadier captain then makes his company take close order, and will either wheel them by subdivisions, or march them in one. If by subdivisions, he places himself on the pivot flank of the first, the eldest lieutenant on that of the second, and the other lieutenant in the supernumerary rank of the first; but if the company is marched in one division, the two lieutenants are in the supernumerary rank. The company then marches, in ordinary time, to the quarters where the colours are lodged, when it halts, and rear ranks take open order. The drum-major unfurls the colours, and gives them cut of a window to the ensigns, who on halting had sheathed their swords. The captain then orders his men to present arms. Officers salute, and the drummers beat a point of

war, which finished, he shoulders arms, closes the ranks, and marches them off in ordinary time, the drummers beating the grenadier's march. On arriving at the left flank of the regiment, the company faces to the right, the ensigns with the colours march in front of the line of officers, the grenadier officers between them and the front rank, as also the drums and music, and the grenadiers in file. Between the other ranks. The commanding officer of the regiment, as soon as the colours arrive on the left flank, orders the battalion to present arms, the officers salute; the music plays God save the king, and the drummers beat the troop. On the colours arriving in the centre of the battalion, the ensigns halt and front, and, when the grenadiers have taken post on the right, the battalion is ordered to shoulder arms.

When the colours are to be *lodged*, on the drummer's call being beat, the ensigns, the drum-major, and a party of drummers and fifers, march and take post in the front of the grenadiers. The battalion present arms, officers salute, music plays, and drums beat. On the captain of grenadiers marching off with the colours, drummers beat the troop. When they arrive at the house, or place where they are to be lodged, the drum-major receives them at a window, the grenadiers present arms, officers salute, and drummers beat a point of war. The ensigns on quitting the colours, draw their swords, and salute with the other officers. The captain will either march his company back, or dismiss them, as he may be ordered by the commanding officer.

When the colours are not to be received, or lodged in form, the serjeant-major, with four serjeants in the centre of the battalion, will take the colours cased, from, or to the place where they are kept, in the following manner. Serjeant-major, the two front rank serjeants carrying the colours on their shoulders, covered in the rear by the two other serjeants and the drum-major, who is to receive them when they arrive at the place of their destination. No compliment is paid by the battalion in this case, and they are generally sent away when the ranks are closed. When the regiment is ordered for a field day, the colours should never be received or lodged in form, as it takes up too much time.

The following is at present the *detail* of the battalion. Field officers—one colonel, one lieutenant-colonel, one major, (by a late regulation field officers have no companies,) ten captains, twelve lieutenants, and eight ensigns. There is no captain-lieutenant. Staff officers—one adjutant, one pay-master, one quarter-master, one surgeon, one assistant-surgeon. Non-commissioned officers—one serjeant-major, one quarter-master serjeant, thirty serjeants, thirty corporals. Drummers—one drum-major, twenty-one drummers and fifers. Privates—five hundred and seventy.

Rules and regulations for his Majesty's forces. Russell's Instructions for the Drill, London, 1803, &c. &c.

BATTARDEAUX, in *Bridge-building*. See *COFFER-dams*.

BATTATA, in *Botany*. See *DIOSCOREA*.

BATTATAS. See *HELIANTHUS*.

BATTAWAY, in *Geography*, a town of Africa on the Grain Coast, easily known at sea by two large rocks, two miles distant from the shore to the west, and also by some high mountains behind the town. This is one of the best built places on the coast; populous and rich, and trades extensively in pepper and ivory. The people, however, are addicted to thieving.

BATTEAU. See *BATEAU*.

BATTEL, in *Geography, Lore, &c.* See *BATTLE*.

BATTEN, in *Carpentry*, a name which the workmen give to a scantling of wooden stuff from two to four inches broad,

and about an inch thick; the length being pretty considerable, but undetermined.

The term is chiefly used in speaking of doors, &c. which are not framed of whole deal, &c. with stiles, rails, and panels like wainscot, but are made to appear as if they were, by means of these pieces, or battens, bradded on the plain board round the edges, and sometimes cross them, and up and down.

Hence batten doors, or windows, are such as seem to be wainscot ones, but are not. These are said to be either single or double, as the battens are fitted on to one side, or to both.

BATTENS of the hatches, in *Sea-language*, are nailed along the tarpaulings, and serve to keep their edges close down to the hatches, in order to prevent the water which washes over the deck from penetrating into the lower apartments of the ship.

BATTEN, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse, 16 miles south west of Waldeck, and 16 north west of Marburg.

BATTENBURG. See *BATENBOURG*.

BATTEN Kill, a small river of America, which rises in Vermont, and after running north and north-westerly about 30 miles, falls into Hudson, near Saratoga.

BATTERBURY, or *BATTERBY Bay*, lies on the west coast of Ireland, about two miles north east from Convitt islands. It has a narrow entrance, but is above 4 miles broad. N. lat. $53^{\circ} 19'$. W. long. $10^{\circ} 22'$.

BATTERIE, is a French term in *Music*, for that kind of *arpeggio*; or breaking of chords in a distinct and detached manner, different from common *arpeggios*, in the execution of which on keyed-instruments, no finger is taken off till the note assigned it is again wanted; and when, on the violin the notes of a chord are not, as usual, swept up and down

in one bow, but either all to be bowed or separated by a tremulous motion of the bow.

In this article of the *Encycl. Meth.* after the definition of the term *Batterie*, and a necessary addition by M. Framery, are inserted, the Abbé Feytaud takes the pen, and in treating the subject metaphysically, manifests deep reflexion and science in the theory of sound; but with a total disregard to the practice of the greatest composers and performers, who have produced pleasing effects by the very means which he prohibits.

BATTERING-RAM. See *ARIES*.

BATTERING-Rams, in *Heraldry*, a bearing or coat of arms resembling the military engine of the same name.

BATTERING, the attacking a place, work, or the like, with heavy artillery. See *BATTERY*.

To *BATTER in Breach*, *battre en breche*, is to play furiously on a work, as the angle of a half moon, in order to demolish and make a gap or breach in it.

In this, they observe never to fire a single piece against the top of the wall, but all towards the bottom, from three to six feet from the ground; they also fire *par camarade*, all together, till they perceive the earth fall from behind the lining of the rampart.

BATTERING Pieces, or pieces of battery. See *CANNON*.

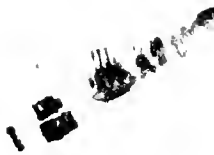

BATTERROW, in *Geography*, lies on the west coast of Africa, 2 leagues from Dixcove, and 5 leagues more from cape Three points to the north of the east.

BATTERSEA, a village and parish near London, in the county of Surry; where above 300 acres of land are occupied by the market gardeners, of whom there are about twenty, who rent from 5 or 6 to nearly 60 acres each. The gardens at Battersea pay seven shillings and sixpence per acre for tythes to their vicar. *Lysons's Environs of London*, vol. 1. p. 27.
